

# Fresh water ecosystems: meaning, types and their properties

*Bhanwar Vishvendra Raj Singh*

*Assistant Professor*

*Department of Geography, Faculty of Earth Sciences,*

*Mohanlal Sukhadia University, Udaipur, India*

## Introduction

The world's demand for fresh water is high, though there is a limited supply. How can we be more responsible with this crucial resource and its ecosystems?

# Key Words

- **DETRITUS:** Matter produced by decay or disintegration of living material.
- **LENTIC:** The vertically layered nature of a lake.
- **LITTORAL:** The region of a lake near the shore.
- **LOTIC:** Flowing water, as in rivers and streams
- **WETLAND:** A shallow ecosystem where the land is submerged for at least part of the year.

# Introduction

Fresh water starts out as water vapor that has evaporated from the surface of oceans, lakes, and other bodies of water. When this vapor rises, it leaves salts and other contaminants behind and becomes “fresh.” The water vapor collects in drifting clouds that eventually release the water back to Earth in the form of rain or snow.

After fresh water reaches the ground through precipitation, it flows downhill across a landscape called the watershed to lakes, ponds, rivers, streams, and wetlands.

More than half of all freshwater on our planet seeps through soil and between rocks to form aquifers that are filled with groundwater. The top surface of an aquifer is called the water table, and this is the depth where wells are drilled to bring fresh water into cities and homes

## Sources : **Earth's aquatic ecosystem**

It include lakes and ponds, rivers, streams, springs, bogs, and wetlands. They can be contrasted with marine ecosystems, which have a larger salt content. Freshwater habitats can be classified by different factors, including temperature, light penetration, nutrients, and vegetation.

- Lakes
- Ponds
- Rivers
- Wetland

# Component

The major components of a freshwater [ecosystem](#) are producers (plants with roots and phytoplankton), consumers (zooplankton, fish, and turtles), and decomposers (bacteria and fungi). Their interaction with [abiotic](#) components (penetration of light, water currents, dissolved [nutrient](#) concentrations, and suspended solids) forms an aquatic ecosystem. The producers supply  $O_2$  to the aquatic systems through [photosynthesis](#). This  $O_2$  is then used by the producers, consumers and decomposers through [aerobic respiration](#). The  $CO_2$  enters an aquatic system from the atmosphere and through aerobic respiration by producers, consumers, and decomposers and it's removed by photosynthesizing producers. The concentrations of [dissolved  \$O\_2\$](#)  and  $CO_2$  in water vary greatly with depth because of differences in the photosynthesis and aerobic respiration rates.

# Freshwater Resources Budget

It is interesting to know that there are nearly  $14 \times 10^8$  cubic km of water on the planet, of which more than 97.5% is in the oceans, which covers 71% of the earth's surface. Wetlands are estimated to occupy nearly 6.4% of the earth's surface. Of those wetlands, nearly 30% is made up of bogs, 26% fens, 20% swamps, and 15% flood plains. Of the earth's fresh water, 69.6% is locked up in the continental ice, 30.1% in underground aquifers, and 0.26% in rivers and lakes. In particular, lakes are found to occupy less than 0.007% of world's fresh water (Clarke, 1994).is available in rivers, lakes and reservoirs.

# India Water Budget

Overall, every year, precipitation in the form of rain and snowfall provide over 4000 cu km of freshwater to India, of which 2047 cu km return to oceans or is precipitated. A small percentage is stored in inland water bodies and groundwater aquifers. Topographic constraints, distribution pattern, technical limitation, and poor management do not allow India to harness its water resources efficiently.

# Types of Fresh Water Ecosystem

- Freshwater ecosystems can be divided into two parts
- [lentic ecosystems](#) (still water) and [lotic ecosystems](#) (flowing water).
- [Limnology](#) ( its branch [freshwater biology](#) is a study about freshwater ecosystems)

On the basis of water depth and types of vegetation and animals there may be three zones in a lake or pond: littoral, limnetic and profundal.

1. The littoral zone is the shallow water region which is usually occupied by rooted plants.
2. The limnetic zone ranges from the shallow to the depth of effective light penetration and associated organisms are small crustaceans, rotifers,, insects, and their larvae and algae.
3. The profundal zone is the deep water parts where there is no effective light penetration. The associated organisms are snails, mussels, crabs and worms.

# Threats to fresh Water

## Prime Threat

Five broad threats to freshwater biodiversity include overexploitation, water pollution, flow modification, destruction or degradation of habitat, and invasion by exotic species.

## Supplementary Threat

Recent extinction trends can be attributed largely to sedimentation, stream fragmentation, chemical and organic pollutants, dams, and invasive species. Common chemical stresses on freshwater [ecosystem health](#) include acidification, [eutrophication](#) and copper and pesticide contamination.

## Message

**Conserve water, conserve life.**

A close-up, first-person perspective shot of a diver's hand reaching out in clear blue water. The hand is wearing a black wetsuit glove with a white logo. The water is crystal clear, showing bubbles and the diver's arm. In the background, a blurry figure of another person is visible, suggesting a group activity. The overall scene is bright and serene, emphasizing the clarity of the water.
