ACKNOWLEDGMENTS

The editors wish to sincerely thank all those who have helped to bring the present venture to a successful completion. They would like to especially acknowledge the important role played by Dr. Asha Rajiv, Director, School of Sciences and IQAC, Jain (Deemed to be University), Bangalore for her relentless support and acceptance of the present book publication and Dr. Pooja Varma, co-editor of this Book, working as a Head of the Department, Assistant Professor, Psychology, Jain (Deemed to be University) for taking the publication at the departmental level.

The editors also thank diligent departmental faculty Ms. Pallavi P., Ms. Manasa Raman and Dr. Sukriti Banda, Assistant Professor, Department of Psychology, Jain (Deemed to be University) for looking after the international conference work on Healthy Ageing in collaboration with NIMHANS, Bangalore in March 2022 efficiently.

The editors would like to record their special appreciation and gratitude for the honourable Vice chancellor of Jain (Deemed to be University), Dr. Raj Singh and his team for his cooperation in taking time out of his busy schedule and contribute towards the Foreword of this book which highlights the importance of healthy ageing from all perspectives in our lives, be it physically, socially, psychologically and cognitively. In addition it brings the attention of the readers towards key content and potent researches covered in the book.

Editors

FOREWORD

The world today, inhabited by more than a billion aged people, is currently witnessing fast rise in proportions of aged people. Projections claim that by 2050 nearly one in five people in developing countries will be over the age of 60. Longer life expectancy, though heartening, this new reality seems impregnated with a host of pressing challenges in view of its failure to guarantee an experience of healthy ageing. This is especially so for those dwelling in the low and middle income countries due to the fact that lack of basic resources and amenities often deprive large numbers of them of a meaningful and dignified life. The COVID-19 pandemic has further exposed glaring disconnects in policies, systems and services. As this global demographic transition remains one of the foremost medical, social and economic concerns of the day, one that impinges upon almost every aspect of society including demographic structure, the phenomenon of 'healthy' ageing is catching the attention of researchers, policy-makers and health professionals alike. Successful or active ageing refutes the stigmatized understanding of age as a mere pathological process and the associated lurking fear that ageing leads to an inevitable decline in the quality of life. Instead it hinges on the non-judgmental concerns relating to physical-mental wellness and cognitive capabilities of aged adults along with their active engagement with life. It is believed that the reduced probability of diseases and debilities will help contain health and social care costs associated with later life. Driven by the growing need to preserve health and vitality and preserve sound lifestyle choices among the older populace, the social policy responses world over seek to foster healthy ageing by largely focusing on the following critical areas of action: social connectedness, nutritious diet and physical activity.

The United Nations Decade of Healthy Ageing (2021–2030) offers a robust platform for concerted decade-long global action on healthy ageing. The initiative intends enhancement of possibilities of engagement with elderly people besides enabling them to realize their potentials, participation and autonomy in a healthy, protective and age-inclusive environment. Resonating with the spirit of UN SDGs, WHO had come forward with its Global Strategy and Action Plan for Ageing and Health for 2016–2020 and its continuation with the WHO programme The Decade of Healthy Ageing 2020–2030. In its ongoing support towards advancement of functional ability and well-being in older age WHO has prioritized country planning and action, research promotion and collection of global data on healthy ageing, aligning health-care systems to the needs of older people, ensuring human resources necessary for long-term integrated care, undertaking a global campaign to combat ageism, and enhancing global network for age-friendly cities and communities.

I am delighted that this publication is on its way to a timely fruition. The critical issue of healthy ageing is multidimensional, influenced heavily by the society and the environment we live in particularly, the people and relationships in our lives together with the attitudes and values we and others around us hold. Successful ageing, therefore, calls for perceptual change among differentiated sets of stakeholders on either side of the spectrum. Set against the backdrop of post pandemic "new" normal the volume contains a rich collection of empirical essays which I am sure will contribute towards a sensitive and nuanced understanding of the phenomenon of ageing from diverse perspectives from an inter-disciplinary approach. The articles reflect a range of rich discussions on value of social support, unconditional self-acceptance and compassion, disciplined spiritual practices, soul-consciousness, emotional intelligence, inner resilience and mindfulness in combating depressive disorder and loneliness syndromes. Contributors candidly spell out simple aerobic exercises, self-care activities and personal hygiene habits for nurturing higher self-esteem, physiological wellness and psychological fitness. The book also has dedicated chapters that elaborate on effective Ayurveda-inspired techniques and smart ICT enablement mechanisms to cope with ageing in the modern world.

Developing holistic and insightful understanding of the problem of 'ageing' is a work in progress and a collective endeavour. The book opens up broader avenues for engagement with our personal journeys of acceptance and adaptations to ageing process both within and without. And, the pieces therein rest on the hope for seizure of these opportunities at its best.

Dr. Raj Singh

Abstract

Background: Aging is a progressive physiological changes in an organism that lead to senescence, or a decline of biological functions and of the organism's ability to adapt to metabolic stress. A roof over the head is a critical need of the elder who are destitute, sick and abandoned by family and those uprooted by disasters. The rapid urbanization of communities and nuclearization of families adds to the old age-related difficulties leading to many elderly shifting to Old age homes (OAH) safety and care. Female elderly faces many difficulties in daily life whether they are living in an Old age home or with family. The living environment along with the adjustment, coping and Quality of Life (QoL) are the main focus of this study.

Aim: To assess and compare the relationship of Quality of Life (QoL), Coping, and Adjustment among female elderly living in old age homes and within a family setup.

Methods and Materials: Forty Elderly female living in Old age homes, and forty female elderly living in the family from the community. They were assessed using WHO QoL Scale-BREF (Hindi version) Global Adjustment scale (GAS) and the ways of coping scale.

Result and Conclusion: Findings of this study indicated that female elderly living in old age homes had a better quality of life, coping, and adjustment in comparison to female elderly living within the family setup. It is not possible to conclude if the Old age homes is better than the community for female elderly. However, there is a need to replicate the study as these can have some influence on policy making for female elderly.

Keywords: Aging, Coping, QoL, Mental health

Introduction

Old age is a challenging period of human life and is associated with many health-related psychological, social, and economic difficulties. Nowadays, Older adults (OA) are highly vulnerable in society (Devi & Roopa, 2013). Their vulnerability increases with age, particularly for females. The elderly female suffer from emotional alienation while living with their son/daughter and grandchildren. Urbanization has caused a drastic change in the socio-economic scenario of the country, leaving the younger generation with no time to interact with the elderly in the family. It is weakening Indian society's traditional bonds between grandchildren and grandmothers thereby making older people more vulnerable due to lack of employment, financial insecurity, ill health and social neglect (Amonkar et al., 2018). The traditional concept of family in India to provide support to the OA is changing with the disintegration of joint families. In past many studies have reported better QOL of the elderly in the family setup as compared to OAH (Roby & Sullivan, 2000). However, with changing social scenario this aspect needs a review.

Elderly female face age-related discrimination, and abuse due to a lack of awareness about their rights and the support system. A typical Indian woman being dependent on others for social, financial, emotional needs is, vulnerable and soft target of wrongdoers. They are forced to lead a life full of distress due to lack of social protection and poverty. Their financial needs are a major concern with the increased life span of elderly female (Neale et al, 1996). Though financial abuse is hard to define, it is reported to be widely prevalent among elderly female. Financial exploitation is the most frequent form of perpetrator-related elder abuse in the US (Jackson, 2017; Sandhu & Arora, 2003).

QoL is widely recognized as an important concept and measure of outcomes in health care, and the concept is emerging more and more often also in connection with long term care. Amonkar et al. (2018) reported higher satisfaction and quality life among elders living in institutional settings than non-institutional settings. Significant differences between the institutional and non-institutional elderly men and women in the area of physical, psychological, level of independence, social relationship, and environment domains of QoL

Adjustment processes in old age are difficult because of the declining physical and mental abilities. Dubey et al. (2011) reported most of the women in OAH were staying there unwillingly. The primary reasons stated for decision to stay in OAH were not having anyone to take care of them at home and not willing to stay with married daughters as per social norms.

Elderly female living in families had a positive attitude towards old age but simultaneously felt it to be a period of dependency. There is yet a lack of consensus about the attitude of the younger generation with their duties towards their older generation is being eroded - and has led to the rapid increase in their institutionalization (Koul, 2015; Singh et al., 2014).

However, there is no consensus about if the family or OAH is a better place to live for the elderly. Kotwal & Prabhakar (2009) found that some of the physical and behavioural symptoms reported by the inmates of OAH are tearfulness and sadness, irritability, social isolation, sleep deprivation, exacerbation of pre-existing pains, and the pains caused by the increase in muscular tension, loss

of appetite, difficulty in sleep, loss of sexual activity, and the loss of interest in daily activities that produce pleasure. Sethi et al. (2013) found that OA who live with family faced more health problems compared to those living with families. Kalavar & Jamuna (2011) reported emotional difficulties of women in OAH. They felt more closeness to their daughters than sons wile staying in OAH However, many felt well away from family in OAH. Thus there is a complex interplay of the social and psychological attributes determine the satisfaction of the Elderly female with living arrangement.

There are lots of gaps in the knowledge regarding the status of elderly female concerning their adjustment, coping, QoL living in families, and OAH. Geriatric health is an upcoming discipline in India. The knowledge is required given the rapidly changing social structure and upcoming need of OAH. The knowledge can be helpful in better designing the psycho-social environment in the OAH for better QOL of elderly female. Hence, we preferred to carry out this study.

Method

Aim: To assess and compare the QoL, coping, and adjustment between elderly female living in OAH and within a family setup.

Methods and Materials: A cross-descriptive research design method was adopted for the study. The study was conducted on OAH and Elderly females residing in families at Rohtak, Haryana. Forty elderly females from authorised OAH and 40 Elderly female from family were selected for this study. Two areas of Rohtak namely, Ram Gopal Colony and Meham were identified for sampling elderly females living in the family. Purposive sampling using the following inclusion and exclusion criteria was followed for collecting the sample. The participants were informed that their participation is purely voluntary and they may withdraw from the study at any stage. They were also assured of confidentiality about the personal information, A written informed consent was taken before enrolling the participants in the study.

Inclusion criteria: The female subjects were considered for inclusion if they were

1. age range between 60-80 years
2. educated up to 5th standard
3. living with family members
4. living in OAH between 2- 5 years (for subjects from OAH)

Exclusion criteria:

1. History of major physical/ psychiatric illness or neurological illness.

Tools:

Socio-Demographic Data Sheet:

It is a semi-structured, self-prepared performa especially drafted for this study. It contains information about socio-demographic variables like age, religion, education, marital status, and domicile.

QoL Scale (WHOQoL-BREF, Hindi version (Saxena et al., 1998)

The Hindi version WHOQoL-BREF Scale was used to assess QoL. This is a short version of the WHOQoL-100 questionnaire contains only 26 items. It can assess QoL in the domains of physical health, psychological health, social relationships, and environment. Higher scores correspond to better QoL. This scale has been widely used for QoL research in India.

Global Adjustment Scale (GAS) (Vohra, 2012)

The adult form of Global Adjustment Scale was used to assess adjustment is valid for subjects aged 20 years and above. The adult form tries to obtain information from the individual regarding Family relationships, Health, Social environment, Emotion, Occupation, Sex-related behaviour, higher scores mean lower adjustment.

Ways of Coping Questionnaire (Lazarus & Folkman, 1988)

It assesses thoughts and actions individual uses to cope with the stressful encounters of everyday living. Ways of Coping Questionnaire has 66 items measuring confronting coping, distancing, self-controlling, seeking social support, accepting responsibility, escape-avoidance, painful problem solving, and positive reappraisal on a 4-point Likert Scale.

Procedure: The subjects were assessed in a single session. The session with each subject lasted for approximately 60-80 minutes.

Bivariate statistical analysis was carried out. Student's t-test and chi-squared test were used for continuous and categorical data respectively.

RESULTS

Table-1

Socio-Demographic Variables between Elderly Females Living in OAH and with Family Setup

Variable		Group		Df	t/x^2
		Old age home	Family		
Age in years (*Mean±SD*)		68.90±6.92	68.37±7.71	79	0.27 NS*
Religion	Hindu	20(50%)	24(60%)	2	1.63 NS*

**NS= Not Significant*

Table 1 shows the socio-demographic variable between Elderly females living in an OAH and within a family setup. In socio-demographic variables, there were no significant differences between both groups.

Table -2

Comparison of QoL between Elderly Females Living in OAH and within Family Setup.

Variable	Group		*t*
	OAH (*N*=40) Mean ± *SD*	**Family setup (*N*=40) Mean ± *SD***	
Physical Health	24.85±3.34	18.22±5.014	6.82**
Psychological Health	24.65±4.38	17.67±3.23	8.09**
Social Health	3.05 ±0.87	2.27±1.06	3.56**
Environmental Health	25.50 ± 3.48	19.62±4.96	6.12**
Total QoL	78.05±4.88	57.80±8.52	10.62**

**=significant at 0.05 Level*

***=significant at 0.01 Level*

Table 2 shows the mean scores and comparison of QoL (domain wise) between Elderly females living in OAH and within the family setup. Significant group difference was found in term of social health and environmental health between elderly females living in OAH and within a family setup. It shows that the mean score of social health of elderly females living with the family was better than the elderly females living in OAH. There were significant differences in scores on all domains. Elderly females living with the family were having better social health than those living in OAH. The mean score of environmental health between Elderly females livings in OAH was better than the elderly females living with family. Its indicate that Elderly females living in OAH were better in environmental health than the elderly females living with family. The mean score of QoL between elderly females living in OAH were better than the elderly females living with family. In the physical health domain, the finding suggested that the mean score of persons who live with family was lower than persons who live in OAH.

Table- 3

Comparison of Global Adjustment between Elderly Females Living in OAH and Family Setup

Variable	B		t
	OAH (*N*=40) Mean ± *SD*	Family (*N*=40) Mean ± *SD*	
Emotional Adjustment	14.90±3.90	23.50±6.21	7.41**
Health Adjustment	16.65±6.72	25.17±8.99	4.80**
Social Adjustment	15.95 ±5.63	25.30±7.82	6.13**
Total Adjustment	47.50±9.92	73.97 ±10.48	7.35**

***=significant at 0.05 Level*

Table shows the comparison of Global adjustment (domain wise) between the groups of elderly females living in OAH and within a family setup. Significant group difference were found in terms of health adjustment, social adjustment, and total adjustment between elderly females living in OAH and within a family setup. Elderly females living with family faced more emotional problems. That's the result they faced more emotional problems in comparison to elderly females. Who lived in an OAH.

Table-4

Comparison of Coping and its Domains Among Elderly Females Living in OAH and within Family Setup:

Variable	Group		*t*
	OAH (*N*=40) Mean ± *SD*	Family (*N*=40) Mean ± *SD*

Coping	54.55±6.99	44.67±10.83	4.84**

***=significant at 0.01 Level*

Table 4 shows the mean score and comparison of coping scores (domain wise) between elderly females living in an OAH and within a family setup. Significant group differences were found in term of distancing, seeking social support, escape avoidance, positive re-appraisal, and total coping.

The mean scores for the elderly females in OAH were significantly higher for all coping domains except for domains of 'seeking social support' and 'positive reappraisal'.

Discussion

India is going through a rapid population change due to industrialization and urbanization of the communities. Consequently, the OA are generally left alone to take care of themselves. The situation is particularly tougher for elderly females due to the feminization of the elderly population and more dependency needs of women (Pande, 2020). Therefore, we aimed to assess the QoL, global adjustment and coping among elderly females living in OAH in comparison to counterparts residing in the community.

We didn't found any difference in the sociodemographic characteristics of the women living in family and OAH in this study (Table-1). However, those the living in OAH reported better QoL on all measures of WHOQoL-BREF than those living with family (table-2). As this comparison is not addressed in many studies, we can simply speculate the reasons. The elderly females living with family is likely to face more emotional problems (Brock & Lawrence, 2011; Geo, 2019). This can be troublesome especially if she is the only representative of her elderly age group. Emotional isolation due to younger people not interacting sufficiently may add to her problems, she might also not be able to confide thereby having no vent to her distress. Further, asymmetrical power dynamics are already being perceived as stressful for the spouses (Mehra et al., 2005; Rayirala, 2016). Though the both the groups didn't had any difference in the marital status (Table-1)Though both the groups didn't have any difference in the marital status (Table 1), even then the same may hold for married women in our study. On the other hand, a person living in an OAH with equal relationships with the same age can share her feelings. The study by Mehra (2005) lend support to our findings and reported that females in OAH had better physical health as well as the psychological health of people living in OAH than people lived with the family. They reported stressful family relationships and lack of family care precipitates poor psychological well-being in the family. However, due to small sample of the current study limits the power of study, we would prefer to deal with our findings conservatively despite good support from literature. The other reasons for not attempting to generalise the findings is that many other studies have reported contrary findings too. A study revealed that elderly females who were living alone had a higher level of financial strain, more depressive symptoms and low level of life satisfaction (Chou & Chi, 2000; Dutta, 1989; Top, 2015). Study has shown that elderly females living in community faced many psychological problems. Social health was good for those respondents who were living in the family because of interactions with many people in the family and visiting relatives, neighbours, religious places etc. In OAH social deprivation, negligence, a sense of isolation and poor social health may reduce the subjective social worth of the individual (Jamwal, 2016; Varma, 2010). Poor social health in OAH can be seen because of reduced religious activities and interaction

with community people. They also noticed good environmental health in OAH .This can be attributed to the fact that the management of any authorised OAH has essential responsibilities for maintaining housing, sanitation, electricity, water (Dey, 2012; Lee, 2020; Whitelock & Ensaff, 2018). The QoL women living in OAH were better than those who were living with family. We feel that the environmental attributes may be playing a role in it. Besides that no family burden, having a peer group, and regular cultural activities may also be contributing to it. People often engage the whole day in these types of activities. Goswami and Deshmukh (2018) conducted a study on OAH and rural community people and found that people living in an OAH had higher QoL than people living in a rural community. Dubey et al. (2011) also reported better QoL in institutional settings for the elderly people. However, it was found that poor QoL, more loneliness, and psychological distress can be seen among the inmates of institutions than those living with families in urban areas of Jammu.

We also aimed to study the social adjustment between the groups of FAO living in OAH and within a family setup. The global adjustment scale was used for this purpose. The Table 3 depicts that the elderly females living in the OAH had better adjustment on all domains. The reasons again are speculative as not many studies have touched this aspect of life in OAH. The elderly females living with family faced more emotional problems people living in an OAH had higher QoL than people living in a rural community most of the day when younger members of the family are either at schools or work place during day. This also restricts their movement outside the home due to their physical and psychological dependencies. The findings of Dubey et al. (2011) ruled that people living in OAH had better emotional adjustment than elderly living with a family member also supported this study. The health adjustment was significantly better for those respondents who were living in OAH primarily because of the availability of doctors on the panel to look after their health as a minimum standard is required for an old age home. Otherwise, the elderly are likely to take their health casually (Akbar et al., 2014). In developed countries sufficient resources are available to the elderly living alone and they can manage themselves. However, this is not the situation in the developing countries (Gupta & Kohli, 2011; Kulkarni, 2009). The OAH facilities in that way may be superior than those available to the community residents. We can say this due to the fact that as per minimum requirement guidelines from the department of social welfare, the OAH besides having facilities like food, care, recreation; they must have a visiting doctor to look after the health of inmates. Availability of these essential services facilities should lead to better physical and psychological health.

In current study the elderly females in the OAH had better social QoL and social adjustment (Tables 2 & 3) than those living in community. The reasons can be manifold. Most of the times the elderly deciding to stay in OAH in India find this as the last feasible option for their survival. They generally face multiple socially adverse events compelling them to decide for staying in old age home. Kulkarni et al. (2009) had found a better social adjustment of those respondents living in family than those in old age home. O'Donnell et al. (2008) however reported low social worth, feeling of social deprivation, negligence, a sense of isolation, and poor adjustment among the inmates of old age home. Thus there appears to be discordance between the scientific observations

and media or public opinion. In the family, people certainly participate in many social occasions related to their relatives, neighbours, and community. In our culture, any visitor to the family generally interacts with the elderly persons as a token of regard. But in OAH, the inmates get little chance to attend a social gathering. In old age home, people live with the same age group so they share their feeling with each other easily. They are self-dependent to take decision about themselves. However with urbanisation of communities such trends are not as frequent as in past at any time. Thus, in coming times the social health of FAO in families may decline. Many other studies also supported this study as Singh et al. (2014) found older adults had a poor adjustment in the community.

As evident from table 4 the elderly females residing in OAH had better coping ability in comparison to the family set up. Sandhu and Arora (2003) also reported that seeking social support for coping is more used by a person living in an OAH in comparison to people living in the family. However, the analysis in the current study was not designed to find the predominant ways of coping by the FAO. In OAH, people live alone so they try to take help from different sources including inmates. Choi et al. (2012) reported that persons living in an OAH used full problem solving coping. In OAH people need to manage all alone unlike those living in family who can get help from other members. Somewhat opposite to it Heydari-Fard et al. (2014) reported that OA used positive re-appraisal coping to reduce their stress particularly in the OAH. They hypothesised that the OA live alone in OAH so they try more to cope with the situation emotionally. They further stated those living in OAH tend to take help from others in the OAH thus using social support coping more often. But many times the OA living in the family get all help from family members so they did not do an effort for any work thus having poor coping abilities in case of distress. Scientific studies are yet needed to verify this speculation.

To conclude we found better QoL, coping and adjustment among the FAO residing in the OAH as compared to their community counterparts. These findings though coming from a cross-sectional study with a restricted sample do suggest a need for educating younger generations about aging and their role in keeping the elders healthy and active. Supporting them physically, socially, and environmentally is equally important. Keeping in view poorer coping, adjustment and QoL in the community dwelling OA mental health professionals, researchers and policy makers need to play equal roles for the OA in community and OAH for preventive, therapeutic and rehabilitative health services. The findings are difficult to generalise due to small sample, non-probability sampling technique and involvement of only one OAH. However, these factors seem to provide need base and direction for further research and policy in relation to the well-being of elderly females.

We recommend that larger sample with probability based sampling covering diverse geographic areas should be selected to study the psychosocial aspects of elderly females so that the findings can be generalised and used for policy making.

2 Attitude Towards Elderly Among Mental Health Professionals

Aaliya Sultana R*, Arlene Fernandes & Dr Sukriti Banda*****

Abstract

An attitude represents a combination of sentiments, beliefs, and behaviours that one has toward a given object, person, thing, or event. Attitudes endure, but they may also change. Ageism is described as any stereotypes, prejudices and discrimination based on their age. There is considerable evidence that there is some extent of ageism present among mental health professionals and this impacts the manner in which services are offered. In order to achieve these objectives, the researchers conducted a study to determine the attitudes of mental health practitioners toward the elderly. The research included 80 mental health practitioners. The variables were measured using a standardized questionnaire namely Kogan's attitude towards old people scale (Kogan, 1961). The study adopted an exploratory research design. t-test analysis was used for statistical computation of the results and testing their significance. The result concluded from the study showed that there is a significant difference in attitude among mental health professionals with respect to living with/without the elderly.

Keywords: Mental health professionals, Ageism, Elderly, Attitude

Attitude Towards Elderly Among Mental Health Professionals

In their influential book, The Psychology of Attitudes, Eagly and Chaiken (1993, p. 1) define an attitude as 'a psychological tendency that is expressed by evaluating a particular entity with some degree of favour or disfavor'. Entailing in this definition is the notion that detailing an attitude includes the outflow of an evaluative judgment about an object. At the end of the day, deciding on an attitude involves making a decision about whether you like or dislike something, whether you

* Research scholar, Jain (Deemed-to-be-University), Bangalore

** Research scholar, Jain (Deemed-to-be-University), Bangalore

*** Assistant Professor, Jain (Deemed-to-be-University), Bangalore

like or disagree with something, or whether you favour or disfavour a certain problem, object, or person.

"Ageism—defined here as social stigma related to old age or older people (Widrick & Raskin, 2010)". It has been shown that ageism is connected with a shortage of mental health resources accessible to elderly adults (Bartels & Naslund, 2013) and that when unfavourable views regarding ageing are internalised by older adults, serious implications to health and well-being may result (Levy, 2009). The public understanding of the elderly is largely influenced based on their family involvement, leading to behavioural changes and attitudes toward the elderly (Cilingiroglu & Demirel 2004; Akdemir et al., 2007). Society's attitude towards advanced age is extraordinarily impacted by certain qualities including the person's age, previous encounters, social convictions, values, and instructive foundation (Akdemir et al., 2007).

Many variables, including older people's attitudes about mental health care and ageism, are theorised to contribute to elderly people's under-utilization of mental health services (Lagana & Shanks, 2002). According to Lagana and Shanks (2002), there seems to be a general propensity among the present elder generation, as well as the general community, to regard psychological issues as a natural part of the ageing process.Since the early 1960s, there has been documented evidence of professional bias or therapists' inability to connect with older clients. This trend is likely to continue to have a negative influence on therapists' work with older clients in the future (Kastenbaum, 1964). (Danzinger & Welfel, 2000; James & Haley, 1995; Meeks, 1990; Woolfe & Biggs, 1997; Zivian, Larsen et al., 1992).

Misguided judgments regarding ageing and negative attitudes of that populace may impede behaviour towards more older adults, correspondence, and the quality and viability of services provided (Gething et al., 2004). For a reasonable public advancement plan and fruitful execution, nations need to decide how their general public, especially the mental health professionals, see advanced age and the assumptions about the elderly.

Research Problem

The number and percentage of India's elderly are increasing, and programmes designed to assure the comfort and safety of this part of the population should rise in tandem, according to the Ministry of Statistics and Programme Implementation's 'Elderly In India 2021' study. According to the estimate, India would have 138 million senior citizens in 2021, with 67 million males and 71 million women. In 2021, the population census showed an increase of nearly 34 million elderly people compared to the 2011 census. By 2031, it is anticipated that this number would have increased by 56 million (Nahata, 2021). With an increasing population of elderly individuals, there will undoubtedly be a greater need for mental health care. Despite this danger, statistics indicate that mental health professionals are undeserving the elderly (Tomko & Munley, 2013). As many as 63% of older persons with mental problems are not receiving the treatments they need, while just 3% of older adults report visiting a mental health professional, according to the American Psychological Association (2003).

Rationale for the Study

The phenomenon of ageism, shown in the forms of age discrimination and age stereotypes, is believed to be a domain-specific phenomenon (Voss et al., 2018). Ageism in health care and long-term care has been extensively studied (Wyman et al., 2011 & Buttigieg et al, 2018). There has been little emphasis on ageism in the mental health profession. Despite this, a number of research conducted over the past three decades have indicated that mental health professionals have unfavourable opinions of elderly persons in general (Bodner et al., 2018). As a result, mental health professionals' views about the elderly should be taken into consideration and whether living with/without the elderly has an impact on the attitudes of mental health professionals

Review of Literature

From the 1950s to the present, an extensive study on attitudes toward the elderly has shed light on the status, development, and impacts on attitudes toward the elderly. This section discusses mental health professionals' views about the elderly.

Chonody et al. (2014) investigate students', academic teaching staff's, and practitioners' comfort levels while spending time with older persons. The purpose of this study was to establish if terror management theory helped predict fear of being around older adults. They also looked at ageism, interaction with older persons, and established demographic characteristics linked with attitudes toward older adults. The findings revealed that dread of ageing, positive ageism, negative ageism, engagement with older individuals, and sex were all key indicators of comfort when interacting with older adults. Educational initiatives addressing common misconceptions about ageing and older individuals may lead to increased comfort when interacting with older adults.

In order to obtain a better knowledge of the characteristics that impact future psychologists' interest in working with older clients, Koder and Helmes (2008) investigated predictors of student intention of working with older clients. A study of 431 postgraduate psychology students in Australia was assessed training, contact, and attitude factors with respect to the elderly. The strongest predictor of interest was having or expecting to undertake a placement in an aged care facility, with the confidence in dealing with the elderly and favourably anticipating old age being attitude characteristics connected to higher interest. According to hierarchical regression analysis, the amount or quality of interaction with older persons, as well as formal education via ageing-related courses, failed to predict interest. The implications for future psychologist training emphasise the necessity of meaningful therapeutic interactions with elderly clients above mere teaching.

Specifically, the research conducted by LEE et al. (2003), which is presented here, aims to investigate this problem among the future generation of clinical psychologists: those who are presently enrolled in graduate school. The responses to questionnaires provided to 25 clinical psychology training programmes in the United Kingdom comprised 371 trainees. The trainees were asked, among other things, why it could be difficult to recruit to the older adult speciality and how recruiting can be improved. According to the findings, many trainees think that clinical psychology, despite many recent breakthroughs, has less to offer older people than other age

groups, despite many recent advances. The comments demonstrate ageism as well as a dread of ageing and death. The most common suggestions for improving recruitment into the older adult clinical psychology specialization were better placements and training, better promotion by clinical psychologists practising in this speciality, and better support, terms, and conditions.

Research Gap

The existing literature shows that there is an unfavourable aptitude among mental health professionals towards the elderly. However, there is a dearth of studies when it comes to inspecting the component of living with or without the elderly. Therefore, keeping this variable as a significant factor this study aims to explore the attitudes of mental health professionals towards the elderly.

Research Question

Is there a significant difference in attitudes of mental health professionals toward the elderly?

Methodology

Aim

To study the attitudes of mental health professionals toward the elderly.

Specific Objective

To study the difference in attitudes of mental health professionals toward the elderly among those living with/without the elderly.

Hypothesis

H_1: There is a significant difference in attitudes of mental health professionals toward the elderly among those living with/without the elderly.

Research Design

An exploratory research approach was used for the investigation.

Variables

Grouping Variables

Living with/without elderly

Test Variable

Attitudes of mental health professionals

Operational Definitions

Elderly

Individuals who are 65 years or older are commonly referred to as 'elderly' since they have completed a natural process that has been measured chronologically (Orimo et al., 2006).

Mental Health Professionals

Mental health professionals are specialists in providing treatment, rehabilitation or support to people with a mental illness or disability (National Standards for Mental Health Services, 2010).

Attitude

Attitude is an acquired tendency to persistently respond positively or negatively to a certain event (Fishbein & Ajzen, 1975).

Sample

Description

The sample consisted of psychologists, counselling and clinical psychologists identified as practitioners within the age range of 25 to 40 years

Sample Size

The sample consisted of 80 mental health professionals, 42 living with the elderly and 38 living without the elderly were included the study

Sample Method

Snowball and Purposive sampling methods were used in this research.

Inclusion and Exclusion Criteria

Individuals having a minimum of one year of experience as a practitioner in the fields of psychology, counselling, and clinical were included in the research. Individuals pursuing their undergraduate and postgraduate in the field of psychology were excluded.

Tools for Data Collection

Consent Form

The use of an informed consent form ensured that the participants were participating voluntarily in the study. The information obtained was only for the objective of academic or research endeavours.

Socio-Demographic Sheet

A socio-demographic data sheet was constructed to obtain information about the participants, including name/initials, age, gender, urban/rural, educational qualifications, years of experience in the mental health field, living with/without old, marital status, and employment.

Kogan's Attitude Towards Old People Scale

The Kogan Attitude Towards Old People Scale is a 34-item self-report questionnaire designed to assess attitudes toward older adults in a variety of settings (Kogan,1961). Seventeen questions are framed negatively, whereas seventeen are phrased favourably, forming the Older Adult Positive and Older Adult Negative subscales. The response options are given utilizing a 6-point added Likert-type scale (1 = strongly disagree, 6 = strongly agree), with a score of 4 given on the occasion a respondent neglected to address an inquiry. Higher ratings suggest that people have an

unfavourable view of the elderly. Researchers have shown a high degree of test-retest reliability. Cronbach's alpha was found to be .81.

Procedure for Data Collection

Mental health professionals residing in Bangalore and Chennai were approached for data collection through Google form. Prior to participating in the study, the researcher obtained informed consent from the individuals. The Kogan attitude toward elderly scale was used to obtain data from participants (Kogan, 1961). The instructions for filling out the form were provided to the participants and the responses were obtained.

Procedure for Data Analysis

The collected responses were scored and interpreted in accordance with the established criteria. The outcomes of the test were tabulated and evaluated using a statistical tool for social sciences (SPSS) (SPSS- 21 Version). Descriptive statistical measures, such as measures of central tendency, variability, skewness, and kurtosis, were used to analyse the data set. As the current study aimed to explore the attitudes of mental health professionals towards the elderly, t-test analysis was used for statistical computation of the results and testing their significance

Ethical Consideration

A consent form was filled out by every participant in the study. The participants were assured of confidentiality. The participants were given the right to withdraw if they were not willing to continue as mentioned in the consent form. The data was exclusively used for academic reasons.

Results & Analysis

Descriptive Statistics

The present section attempts to analyse the descriptive statistics to determine measures of central tendency (Mean), standard deviation and measures of skewness and kurtosis of the Participant's attitudes toward the elderly

Table 4.1

Results of the Descriptive Statistical Analysis of the Variables of the Study

Dependent Variable	*N*	*Mean*	*SD*	Skewness	Kurtosis
Attitude Towards Elderly	80	135.74	31.029	-.386	-.120

From the above table, it can be inferred that the mean score of the attitude towards the elderly was found to be 134.74 with an SD of 31.029. The skewness and kurtosis were -.386 and -.120 respectively, which clearly indicates that the measures of skewness and kurtosis were identified between the range of -1.96 and +1.96., hence the distribution of data is normal.

Inferential Statistics

The present section attempts to analyse the significant difference in attitudes of mental health professionals with respect to living with/without the elderly

Table 4.2

Results of the Independent Sample t-test

Test Variable	Living with/without Elderly	*N*	*Mean*	*SD*	*t*	*df*	*Sig.*
Attitude Towards Elderly	Living with Elderly	42	154.88	20.973	7. 609	78	.000
	Living without Elderly	38	114.58	26.317			

For the research sample (N=80), the mental health professionals living with the elderly (M=154.88, SD=20.973, n=42) has obtained a higher score on the attitude towards elderly than mental health professionals living without elderly (M=114.58, SD= 26.317, n= 38) and was significant at 0.01 level. Therefore, p<0.001, hence the alternative hypothesis that there is a significant difference in attitudes of mental health professionals with respect to living with/without the elderly has been accepted.

Discussion

The aim of the study is to study the attitudes of mental health professionals towards the elderly. The hypothesis stated that there is a significant difference in attitudes of mental health professionals with respect to living with/without the elderly. *t*-test analysis was used for statistical computation of the results and testing their significance. The results obtained indicated that there is a significant difference in attitudes of mental health professionals with respect to living with/without the elderly. Thus, the formation of attitudes, with the role of family and living circumstances has a substantial impact on the development of these attitudes towards the elderly among mental health professionals. It can also be inferred from the evidence that mental health therapists continue to be less prepared to engage with and provide therapy to older persons than younger adults, have typically unfavourable attitudes about older adults as psychiatric patients, and lack appropriate professional understanding of the geriatric population. Additionally, internalised ageism has an effect on older patients' relationships with the mental health care system and might lead to an unwillingness to seek mental health care services (Bodner et al., 2018). The study has scope for further research with respect to its sample size and also the inclusion of other demographic details.

Limitations and Directions for Future Research

Mental health is one of the contemporary topics that is widely discussed and every individual should have equal access to the same. Professionals working in this field have an important role to play in order to spread this awareness. Therefore, it becomes essential that these professionals have an unbiased attitude towards the entire population. According to research conducted over the past

30 years worldwide, many mental health professionals are unwilling to engage with older adults, have misconceptions about the efficacy of geriatric psychotherapy, and lack professional expertise in the geriatric population (Bodner et al., 2018). Keeping this as a basis, this study explored the attitudes of mental health professionals toward the elderly population and the results obtained helped determine whether living with/without the elderly is influential in shaping these attitudes. However, the study also has a few limitations which will broaden the scope of further research for this study. The sample recruited for this study was minimal in nature and therefore the aspect of generality of the results remains as a limitation to the study. Also, many of the demographic details and environmental factors which play a crucial role in the development of attitudes were not taken into consideration. Larger sample sizes with equal representation from various Indian states could be recruited for future studies. To acquire qualitative data to validate the conclusions of the research, interviews may be done with mental health experts. These interviews can also be used to investigate the many variables that influence their attitudes about the elderly. On the other hand, from the various research evidence, it can be taken into consideration that mental health professionals should be encouraged to seek training programmes for dealing with the elderly. The validity of mental health diagnostic criteria and accessible assessment tools requires more research. Improved cooperation and exchange of information among health professionals in the area of gerontology may result in improved evaluation and treatment capacities in serving the elderly.

Conclusion

The aim of the study was to study the attitudes of mental health professionals towards the elderly. The hypothesis stated that there is a significant difference in attitudes of mental health professionals with respect to living with/without the elderly. t-test analysis was used for statistical computation of the results and testing their significance. The results obtained indicated that there is a significant difference in attitudes of mental health professionals with respect to living with/without the elderly. However, there are certain limitations with respect to the sample recruited and the inclusion of other demographic variables which will further act as directions for future research in this area.

3 Relationship Between Self-Compassion and Psychological Wellbeing among Geriatric Population in India

Aditi Dubey* &
Aparajita Chakraborty **

Abstract

In the last few decades, advancement in the field of medical sciences and technology has changed our understanding of the process of aging. Studies suggest increased life expectancy as more individuals are entering into a ripe and active old age. There are multiple interpersonal and intrapersonal factors behind it, one could be self-compassion. Self-compassion (SC) is a construct to describe healthy self-to-self relation, which involves a non-judgmental attitude toward one's pain, inadequacies, and failures, along with the perception that these are part of the greater human experience. It encompasses three fundamental components: (1) self-kindness (2) common humanity and (3) mindfulness. There are growing studies indicating the role of self-compassion in a wide range of desirable psychological outcomes, at inter and intrapersonal levels, especially among adolescents. However, very few studies have been done on the geriatric population. In this regard, the present study investigated the relationships between self-compassion and psychological well-being among 65 old adults (Mean age 67 yrs) using Self-Compassion Scale for Adults Short form and the Psychological Wellbeing Scale (Ryff 18 items). Results indicated that self-compassion is and a few of its components are positively correlated with psychological well-being and few of its components indicate its wider role and application in this population as well and it also throws light on the probable usage of self-compassion-based psychotherapies among this population.

Introduction

The 14th Dalai Lama, known as Gyalwa Rinpoche said, "We can never obtain peace in the outer world until we make peace with ourselves".

With the advent of technology, exponential industrial growth, development of advanced medicine health care facilities, enhanced lifestyle, healthy nutrition, and exercise there has been an increase in life expectancy of human beings because there are modern equipment and assistant services readily available for the old people. However, studies have found that during late adulthood, many factors like impairment due to declining in health, being widowed, having a low religious commitment are linked to lower self-esteem (Giarrusso and Bengston, 2007) and consequently affect immunity (Walston et al. 2009) putting them at risk of physical illness(Bauer, Jeckel and Luz, 2009). Hence, it is necessary to explore the protective factors that can play a pivotal role in the conceptualization of cases, understanding the goals of psychotherapy, and eventually enhance the overall well-being and quality of life of the elderly. In this regard, a construct called Self-compassion can be introduced. Derived from ancient Buddhist concept, it is a "healthy self-to self-relation", comprising of three core components, namely self-kindness (exhibiting warmth and kindness towards oneself as opposed to harsh criticism); Common humanity (it stands for universality and unavoidability of basic human emotions like pain and suffering) and Mindfulness (Paying attention to the emotions at present without being overly attached to it)(Neff, 2003; Hollis-Walker and Colosimo, 2011). Self Compassion turned out to be a health-promoting behavior as many studies found its link with enhanced optimism, adaptive coping, emotional intelligence, and health benefits as well. (Neff, 2003). A study by Ashley and Mark (2013) on 121 participants with a mean age of 76 years predicted the effect of self-compassion on the positive response towards aging. It is also associated with well-being in later stages of life (Allen et al. 2012). There are studies suggesting a mediating role of self-compassion between adult attachment style and well-being. (Moreira et al., 2016; Neff & Faso, 2015). Psychological well-being or Eudamonic Well-being is a concept developed by Ryff (1989) which describes the optimal functioning of a human being with respect to developmental, personal, and humanistic tradition, thereby focusing on the fulfillment of human potential. (Keyes et al. 2002). Ryffs' model of psychological well-being is based on life-span development and comprises 6 components namely: Self-acceptance, Autonomy, Purpose in life, Environmental mastery, Personal growth, and Positive relation with others. (Homan, 2016). Interestingly, a study by Bendre (2020) on the Indian population found that older adult women were more self-compassionate with better well-being than middle-aged women. As psychological well-being emphasizes the pursuance of human potential, its associated factors are needed to explore as well such as self-compassion.

However, there are very few studies on the Indian population to explore the relationship between self-compassion and psychological well-being. Therefore, the study aims to explore the relationship, if any, between self-compassion and psychological well-being in the geriatric population.

Objective

To explore the relationship between self-compassion and psychological well-being among older adults.

Hypothesis

1. *Ho*: There is no significant relationship between self-compassion and psychological well-being among the geriatric population.
2. *Ho*: There exists no significant relationship between Self-compassion and Self-Acceptance among the geriatric population.
3. *Ho*: There exists no significant relationship between Self-compassion and Autonomy among the geriatric population.
4. *Ho*: There exists no significant relationship between Self-compassion and Purpose in Life among geriatric population.
5. *Ho*: There exists no significant relationship between Self-compassion and Environmental Mastery among the geriatric population.
6. *Ho*: There exists no significant relationship between Self-compassion and Personal Growth among the geriatric population.
7. *Ho*: There exists no significant relationship between Self-compassion and Positive relations with others among the geriatric population.

Methodology

It is a correlational, cross-sectional, non-experimental, and quantitative study with the objective to assess the relationship between self-compassion and psychological well-being among the geriatric population, in India

Participants

65 older adults (45 males and 20 females), of Indian nationality, aged 60 yrs and above, of both sexes, participated in the study, who self-reported to have no current psychopathology or history of psychiatric illness. Data was collected through an online platform with the snowball method.

Measures

1. Self-Compassion Scale Short form of 12 items was employed to assess the self-compassion, developed by Raes et al. (2011) on a 5 point Likert scale ("almost never" to "almost always"). Items were reversed and scored accordingly. This scale has good internal consistency (Raes et al., 2011) and a near-perfect correlation with the original scale (Neff, 2003)
2. Psychological Well-Being was measured by the Psychological well-being scale of Ryff et al. (2010) with 18 items. It comprises 6 domains namely Self-acceptance, Autonomy, Purpose in life, Environmental mastery, Personal growth, and Positive relation with others and was measured on a 7 point Likert scale.

   In the present study, the reliability of these scales were 0.79 and 0.75 respectively with subscales ranging between 0.54 to 0.79.

Results

Table 1

Demographic Details of the Participants

Domain	*Mean*	*SD*
Age	67 yrs	4.7

Table 2

Indicating Correlation between Scores of Self-compassion and Psychological Well-being

Variable	*N*	1	2
Self-Compassion	65	-----	
Psychological well-being	65	.448**	-----

** p < 0.05*

*** p < 0.001*

DISCUSSION

The data was found to be normally distributed as the scores had significant value on Kolmogrov-Smirnov's test(0.200) and Shapiro-Wilk value (0.25) was > 0.005, hence parametric statistics were used. To assess the relationship between these two variables (Self-Compassion and Psychological Well-being), Karl Pearson's correlation was used.

From Table 1, which is describing the demographic details of the participants, it can be inferred that 654 older adults (454 males and 20 females) participated in the study with a mean age of 67 years. Their age range is between 61 and 82 years where 57.8% of the participant's hem reported having any form of physical illness at present such as diabetes (42.9%), heart conditions(17.1%), or others (40%).

From table 2, it can be inferred that there exists a moderate strength of positive correlation (r = 0.448) between the scores of self-compassion and psychological well-being, which is significant at 0.001 level of significance. Hence it can be indicated that an increase in self-compassion will enhance psychological well-being as well. This finding is consistent with the findings of a study by Allen et al., (2012) and Homan (2016), indicating a significant relationship between self-compassion and Eudamonic or psychological well-being. Hence first alternate hypothesis is accepted indicating that there exists a significant relationship between Self-compassion and psychological wellbeing among geriatric population, in India. nstead of being resentful towards the process of ageing, a self-compassionate outlook enables adaptive coping with the aid of kindness, care,deep understanding shared human experience and with objective perspective on negative feelings and emotions (Neff, 2003) Autonomy can be understood as a state of setting and following one's own rule, (Evans, 1983) but the process of ageing has detrimental effects in the latter stage of life. Hence, self-compassion can be one important factor associated with autonomy, as it helps in acceoting the senescence, as a feeling of common experience, universal and inevitable in nature.

From table 3, it can be inferred that self-compassion has a weak but positive correlation with Autonomy among the geriatric population (r=0.300) significant at 0.05 level. As a healthy and functional being, auntonmy plays a crucial role during the process of aging (Perrig-Chiello et al. 2006) Hence, instead of being resentful towards the process of ageing, a self-compassionate outlook enables adaptive coping with the aid of kindness, care,deep understanding shared human experience and with objective perspective on negative feelings and emotions (Neff, 2003) Autonomy can be understood as a state of setting and following one's own rule, (Evans, 1983) but the process of ageing has detrimental effects in the latter stage of life. Hence, self-compassion can be one important factor associated with autonomy, as it helps in acceoting the senescence, as a feeling of common experience, universal and inevitable in nature.

There is a weak positive correlation between self-compassion and positive relations with others (r = .309) which is significant at 0.05 level. As understood by Socioemotional selective theory (Laura Carstensen, 2008), that in due course of time, the older adults become selective about their social network therby giving emphasis to emotional satisfaction from rewarding relationship to enhance positive experiences; Self-compassion can be associated with it as it has interpersonal benefits

like altruism, empathy and social connectedness (Neff et al. 2007; Welp and Brown (2014))

There exists a positive correlation of moderate strength between self-compassion and self-acceptance, siginifcant at 0.001 level. (r = .358) Self compassion comprises of Self-kindness as one if its core elements, which lays emphasis on treating oneself with warmth and care amidst adverse situation. Therefore, it has a relationship with self-acceptance, because they are closely related. Studies found that treating oneself with forgiveness after acceptance will enhance interpersonal relations (Homan, 2016)

Rest subscales of Psychological well-being that is Environmental mastery, personal growth, and purpose in life had positive correlation with self-compassion but not at a significant level. Study by Kim et al (2010) found association between self-compassion and self-appraisal that were associated with growth outcomes.

From the current study, self-compassion was found to be related with psycholigical well-being and few of its domain, among the older adults. Therefore future studies can focus on the effect of these varaibles and on ways of enhancing self-compassion . There are amny studies that show beneficial effect of self-compassion on the eudamonic well- being and promote overall psychological functioing. (Leary et al. 2007; Albertson et al. 2014; Baker and McNulty 2011;) Lastly, psyhotherapies can emphasis on this construct in establishing the goal for treatment to enhance mental health and well-being.

Conclusion

The process of aging has its own challenges to be met. There are extensive researches trying to explore and find protective factors to enhance and facilitate a better experience for the senile. Here, Self-compassion can play a crucial role as it was found to be positvely correlated with psychological well-being and few of its domains like autonomy, positive relations with others and self-acceptance, in the current study. Therefore, more studies can explore its role in therapies to promote well-being among the older adults.

4 Psychological Distress among Elderly Naga Cancer Patients in Relation with Hope and Social Support

Sashirenla Mollier*

Abstract

Objective: The study was conducted to determine the prevalence of psychological distress among elderly Naga cancer patients and find its relationship with Hope and Social support.

Methods: The study followed purposive sampling method which included 48 elderly Naga cancer patients presently undergoing treatment in various hospitals across Nagaland. Data were collected using Herth Hope Index (HHI) for assessing the levels of hope, Berlin Social Support Scale (BSSS) and DASS-21 (Depression, Anxiety and Stress scale-21) to assess the levels of depression, anxiety and stress. The data was analysed by using SPSS-v21.

Results: Out of the 48 cancer patients, there were 36 males and 12 females. Among the total, it was seen that 45%, 60% and 66% of the patients were having some levels of depression, anxiety and stress respectively, while the others were found to be normal. Pearson Product Moment Correlation revealed that there was significant negative correlation between hope and psychological distress i.e., depression (r= -.644, p< .001), anxiety (r= -.498, p< .001) and stress (r= -.479, p< .001) of elderly Naga cancer patients. On the other hand, the study showed no significant correlation between social support and psychological distress of elderly Naga cancer patients (p<.01).

Conclusion: Psychological distress is found to be prevalent among elderly cancer patients. The findings of the study highlight the need for psychological care in the treatment of elderly cancer patients.

Introduction

Cancer is life threatening, fear, despair and dejection associated, and its diagnosis is perceived by many to be their death sentence. It is a disease causing a biological disturbance where there is no organ in the human body in which cancer cannot develop. It is reported in study done by Given & Given (2009) that approximately 60% of cancer incident and 70% of cancer mortality occurs among adults aged 65 and older. This shows that cancer affects the elderly people greatly as much as it affects the younger ones. Coupled with the burden of being aged and weary among the elderly, the symptoms of cancer will much affect physically as well as emotionally and psychologically adding more despair to one's life. It is important that psychological distress particularly depression, anxiety and stress be considered a necessity for patients to undergo screening as it remains to be a strong contributor in interfering with the patients' health promotion.

Nagaland is reported to have enormous growth of cancer patients and today it has become like a trend among the Nagas on being diagnosed with this disease. When observed, the older generation in general tend to have very light concern in undergoing regular medical check-ups or in particular lack knowledge about cancer. This could be a reason why illnesses such as cancer remain undiagnosed and untreated among the older people. Additionally, we might also find that many people live within a limited budget provision hampering one to go ahead for treatment. Due to these possible reasons, high prevalence rate of cancer is seen among the elderly Nagas where many are diagnosed only in late stage, resulting in high rate of morbidity and mortality. It should also be understood that with increasing severity of the illness, psychological disorders on the other hand also ushers wherein, a patients' quality of life is likely to worsen. Thus along with treating the disease, mental health should also be considered important. The present study thus felt the need to find out the levels of psychological distress such as depression, anxiety and stress among elderly Nagas afflicted with cancer and how hope and perceived social support as a positive aspect is helping one to cope with the illness.

Objectives

1. To find out the prevalence of psychological distress among elderly Naga cancer patients.
2. To find out the correlation between Hope and psychological distress levels of elderly Naga cancer patients.
3. To find out the correlation between Perceived Social Support and psychological distress levels of elderly Naga cancer patients.

Methodology

Sampling technique: The study was conducted by following purposive sampling method which is a non-probability sampling method in which a researcher selects the respondents according to his/her convenience that is based on the typicality of the cases to be included in the sample.

Sampling size: It included 48 elderly Naga cancer patients presently undergoing treatment in various hospitals which has provisions specifically for treating cancer patients across Nagaland. Besides, data were also collected from patients who were being monitored at home. These were

patients availing treatment from outside the State of Nagaland or those who visit hospital only on a basis of monthly regular treatment. The study excluded patients who were admitted in Intensive Care Unit (ICU) at the time of data collection and those who exhibit symptoms of mental disorders. Data were collected between the years 2021.

Tools used: Data were collected using DASS-21 (Depression, Anxiety and Stress scale-21) to assess the levels of depression, anxiety and stress, Herth Hope Index (HHI) for assessing the levels of hope and Berlin Social Support Scale (BSSS) to assess the levels of social support. The data was analysed by using SPSS-v21. Mean, standard deviation, Pearson product correlation was used to analyze the data.

Results

Out of the 48 elderly Naga cancer patients, there were 36 males and 12 females. Among the total, it was found that 45%, 60% and 66% of the patients were having some levels of depression, anxiety and stress respectively, while the others were found to be normal. The following Figures (Figuresno.1, 2 and 3) show the severity levels of depression, anxiety and stress precisely according to DASS-21 scale.

Figure 1

Showing severity of depression among elderly Naga cancer patients.

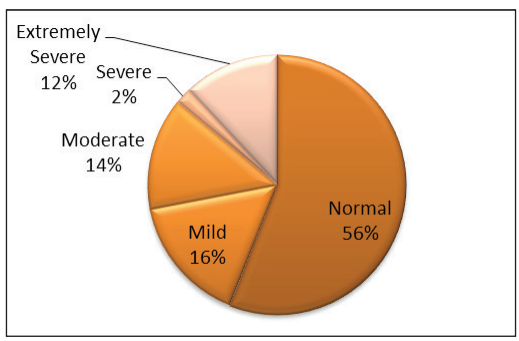

Figure 2:

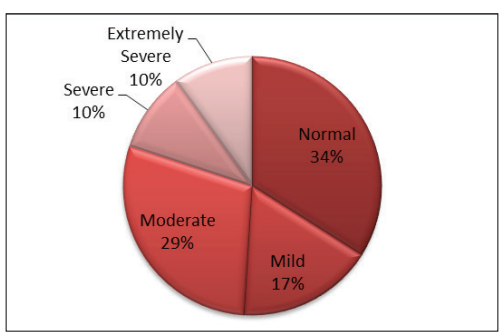
Showing severity of anxiety among elderly Naga cancer patients.



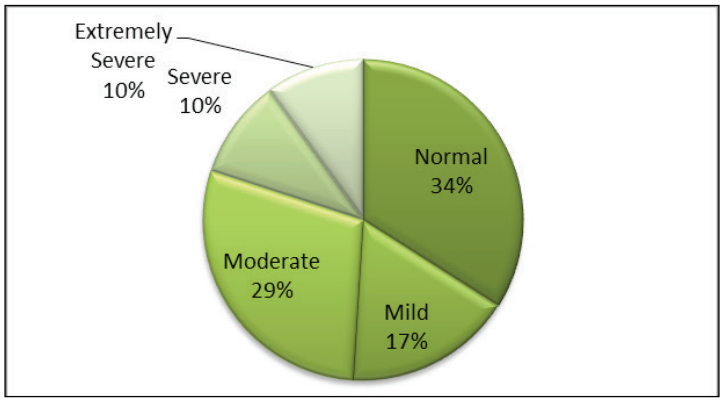


Figure 3:

Showing severity of stress among elderly Naga cancer patients.

To evaluate the correlation between hope and psychological distress, Pearson Product Correlation was used which revealed that there is significant negative correlation between hope and psychological distress depression (r= -.644, p< .001), anxiety (r= -.498, p< .001) and stress (r= -.479, p< .001) of elderly Naga cancer patients. This shows that an increase in hope leads to decrease in depression among elderly Naga cancer patients. Table 1 shows mean, standard deviation and correlation between hope and psychological distress among elderly Naga cancer patients.

Table 1

Mean, Standard Deviation and Correlation between Hope and Depression Among Naga Cancer Patients.

Psychological Distress	*Mean*	*SD*	*r*
Depression among cancer patients	2.02	1.39	-.644
Anxiety among cancer patients	2.29	1.38	-.498
Stress among cancer patients	2.48	1.33	-.479

*p< .001

To evaluate the correlation between perceived social support and psychological distress, Pearson Product Correlation was used which revealed that there is no significant correlation between social support and psychological distress of elderly Naga cancer patients (p<.01).

Discussion

Palliative care to elderly people with cancer includes Palliative care to elderly people with cancer includes several issues. It will include the treatment to win over cancer, dealing to overcome psychological distresses which usually come as a package with cancer diagnosis and along with

the general old age care. The findings of the present study showed that there is prevalence of psychological distress namely, depression, anxiety and stress with 45%, 60% and 66% respectively while the others were found to be normal. Similar finding was reported by study done by Hong el al. (2015) which shows that psychological distress is exhibited among elderly cancer patients to some degree. Study done by Jahanara (2007) reports that hope is positively related to psychological well-being and negatively correlated to psychological problems. The result of the present study is consistent with this finding which shows that hope and psychological distress are negatively correlated. This could be so because hope is regarded as a feeling that allows one to sustain belief in dire circumstances. Perceived social support which is considered as an individual feeling of being valued, cared and loved by others showed no significant correlation between social support and psychological distress of elderly Naga cancer patients ($p<.01$).

Conclusion

The findings of the study highlight the need for psychological care in the treatment of elderly cancer patients through various ways such as giving frequent counselling and also providing support by professionals, caregivers, families and friends. It is important to note that psychological distress is common among elderly cancer patients and can greatly affect them in various ways. The result also suggests that hope and perceived social support may be considered an important dimension in reducing psychological distress and its symptoms.

5 Diabetes and the Elderly in the Post-Pandemic World

Pavithra Parthasarathy* &
Dr. Pooja Varma**

Abstract

This paper aims to discuss the impact of COVID-19 on the management of diabetes in the elderly. The initial days of the pandemic focused on identifying treatments and controlling the spread of COVID-19. Individuals with pre-existing chronic conditions, like diabetes and those older than 60 years, were a high-risk population and to experience more severe symptoms of the disease. COVID-19 has led to the development of the new normal. This population has dealt with changes both physically and mentally. Apart from problems relating to diabetes, social isolation, dependence on technology, lack of access to health care and medication, lifestyle changes, loss of family/ friends to COVID, changes in the economic conditions in the family are some of the issues addressed in this paper. On the psychological aspect, dealing with the stress due to COVID, anxiety, depression, fears, contamination, social isolation, lack of social support, emotional outbursts, helplessness , and sleep issues are common symptoms that directly impacted lifestyle therefore on their diabetes management. While the development of psychological issues is on the rise, lack of awareness and the stigma attached to seeking help adds as an additional cause of concern among patients with diabetes. This paper highlights the key issues of elderly diabetic individuals in the post-pandemic world.

Keywords: COVID-19, Elderly, Diabetes, Lifestyle management, Post-pandemic world

Introduction

Diabetes mellitus is a complex chronic disease that occurs when the pancreas does not produce enough insulin or the body cannot use its insulin. In 1985, 30 million people suffered from diabetes, 537 million in 2021 and it is estimated to affect about 783 million by 2045. (Abdi et

* Research Scholar,Jain (Deemed-to-be University), Bangalore

** HOD, Department of Psychology, Jain (Deemed-to-be University), Bangalore

al., 2020, International Diabetes Federation , 2021). In 2021, about 74.2 million Indians were diagnosed with diabetes. ("Down to Earth", 2021). While diabetes was considered to affect the "wealthy Western" nations, it has become a major cause for concern among the low and middle-income countries affecting even the younger age groups (Pradeepa & Vishwanathan, 2021) Physical inactivity, imbalanced diet and abdominal obesity are important risk factors for the development of type 2 Diabetes mellitus (T2DM). Despite the obvious magnitude of the problem, only around 50-75% of Indians showed an awareness of the condition (Deepa et al., 2014). The macrovascular (strokes, peripheral vascular diseases and coronary artery disease) and microvascular (neuropathy, nephropathy and retinopathy) complications further add to the woes of people with diabetes (Misra et al., 2014). The key factors that play a role in diabetes management include food insecurities, homelessness, literacy, language barriers, psychological factors like cognitive dysfunctions, personality factors, health literacy and health behaviours.

The spread of COVID-19 began in December 2019 with a catastrophic growth by 2020. The World Health Organisation declared it as a state of a pandemic in March 2020(Cucinotta & Vanelli, 2020). The first case in India was declared in January 2020(Andrews et al., 2020). With the spread of the pandemic, the government initiated social distancing and travel restrictions. In a short period, a complete lockdown was announced in India. People were asked to stay indoors and avoid contact with the outside world. The government arranged for the essentials to be available in all areas, to avoid crowding and the spread of COVID.

The psychological impact of COVID is far worse than the medical impact. Society as a whole experienced panic, anxiety, fear, emotional outbursts, stigma and mass hysteria(Banerjee, 2020). People with chronic health conditions like diabetes and the elderly were especially vulnerable to these symptoms. American Diabetes Association has identified that the presence of diabetes increases the severity and complications of symptoms of COVID (American Diabetes Association, 2020). Along with the risk posed due to chronic illness, psychological symptoms can accelerate, leading to the development of psychiatric/psychological disorders. The strain of psychological illness in turn will worsen the experience of symptoms. Post- COVID/post-pandemic refers to the time after the third wave of COVID. This paper aims to understand the psychological issues in the post COVID world, in the elderly patients of diabetes in India.

The objective of this paper is to identify the common problems faced by elderly patients with diabetes in the post-pandemic world.

Methods

Secondary data were accessed on PubMed and Google Scholar for studies between 2020- 2022 Feb:

- Elderly diabetes self-care
- Elderly diabetes self-management

- Elderly diabetes self-management education
- Elderly diabetes self-management India
- While all studies included contained patients of diabetes, there were limited information specific to self-management behaviours in the elderly population.

Key findings

The initial search for diabetes self-management during COVID-19 identified many challenges faced by individuals with diabetes. No studies specifically targeted the elderly population. This article compares and contrasts the effects of covid faced by elderly patients with diabetes.

Studies during the pandemic suggested that contracting covid lead to increased blood sugar levels. (ADA, 2020) This finding suggests that covid has a direct impact on blood sugar levels. Individuals with pre-existing diabetes were more vulnerable to serious symptoms of covid. The risk increases with age and therefore it is important to address the issues faced by elderly patients with diabetes. Diet, physical activity, medications and monitoring – the key factors in diabetes self-management are discussed in comparison with the initial pandemic period.

The first and second waves of covid had a strong impact on the lifestyle of people with diabetes. Lack of contact with the external world led to increased emotional experiences, loneliness, frustration and boredom (Banerjee et al., 2020). Increased access to information regarding no of positive cases, number of deaths and local containment zones lead to increased fear and anxiety. This circular relationship of boredom, information overload, lack of motivation and a sense of helplessness caused erratic changes in sugar levels. Among older adults, the magnitude of such problems increased multifold. Digital solutions lead to increased reliance on technology, which has been an added burden for the elderly due to the digital divide.

1. **Diet:** Initial lockdown period led to major changes in eating patterns. While the pandemic has fuelled unhealthy food practices, some positive changes were also noticed. Studies indicated increased food quantities and food groups among patients with diabetes. Lack of availability of diabetic diet, increased access to unhealthy food, erratic meal timings, increased quantity of food, snacking, increased food cravings, changes in sleep patterns, loss of appetite, no socialising, comfort eating are some common changes noticed during the lockdown period. Kishimoto et al. (2021) and Ruiz-Roso et al. (2020) state that it involved potential health consequences, especially on patients with Type 2 Diabetes Mellitus (T2DM).

   Among the older adults, mixed results were obtained on eating patterns and diet quality. Older adults were able to maintain dietary patterns better than the younger population but increased sugary foods and increased snacking led to worsened glucose levels. (Nicklett et al., 2021).

2. **Physical activity:** Lockdowns and travel restrictions have had a huge impact on the physical activity level among older adults. Unhealthy nutritional needs along with increased sedentary behaviours have resulted in erratic blood glucose levels.(Grabowski et al., 2021) Disruption of daily life activities along with lack of physical space created problems in reaching the optimal level of physical activity. From regular exercise, cessation of all forms of physical movement

caused increased weight gain and problems associated with weight management. Physical activity not just helps in blood sugar control but also in the prevention of complications and building immunity.

The elderly population specifically faced greater problems in managing their physical activity regimes. Inability to go out, fear of covid along with the need to maintain their sugar levels and overall health acted as an additional stressor.

3. **Medications and monitoring:** Access to medications took a major turn during covid. Inability to visit doctors, non-availability of doctors, lack of transportation and restrictions led to changing trends in diabetes management. Monitoring of glucose levels and other testing parameters were not available. This led to more wait time for testing and delayed results. Monitoring day to day changes in the sugar levels along with the other changes in diet and physical activities caused increasing stress levels. With a lack of boundaries between work and personal life, monitoring was not considered a priority.

   Among the three main factors in diabetes management, diet and physical activity seemed to have more impact in comparison with medications and monitoring. Changes in the financial conditions of the household, the loss of family members and friends resulted in a change in mindset. Now, after the end of the third wave, a new normal has set in. While elderly diabetes patients had an initial difficulty managing the changes, learning newer coping mechanisms along with the added advantage of having social support from family and friends, has led to better management of blood sugar levels. The use of technology like home monitoring kits, apps to manage diet, physical activity, sleep trackers, step trackers which narrow the digital divide have become a boon in the post covid world. Initial studies indicated that older adults had better emotional regulation and resilience, the long-term effect especially among elderly diabetics needs to be studied (Vahia et al., 2020).

Conclusion

The post-pandemic period has resulted in a better understanding of diabetes management among the elderly. Lockdown resulted in making healthier food choices. Understanding the role of nutrition along with a need to stay healthy promoted the development of healthy behaviours. While restrictions lead to innovation in managing physical activity, online yoga, Zumba classes, devices to track activity levels have assisted in the improvement of healthy behaviours. As with any major event, COVID-19 initially lead to many complications and problems. With time, individuals have learnt to cope and even improve living conditions.

6 A Positive Psychology-Based Intervention Model (C. A. R. E) for Pain Catastrophizing and Well-being among the Elderly during the pandemic: A Randomized Control Trial

Sudha. R* & S. Gayatridevi. **

Abstract

Ageing is a natural process in life. Ageing brings with it experience, wisdom, courage, knowledge and on the flip side pain, illness and loss. This may bring psychological ill-being and stress. Positive Psychology postulates that the absence of "Negative", that is the absence of disease, does not ensure Well-being. Applying this construct, an intervention model was constructed and named "The C. A. R. E intervention Model". C. A. R. E is an acronym that can be expanded as follows:

C: stands for Compassion and Self-Compassion

A: stands for Achieving a Purpose in Life

R: stands for Relationship Building

E: stands for Enhancing Positive Emotions

The C. A. R. E intervention consisted of activities and exercises designed to develop compassion and self-compassion, achieve a sense of purpose in life, build relationships and enhance positive emotions.

The sample of 68 elderly persons both male and female who were COVID survivors was selected through purposive sampling. They were then randomly assigned into an experimental group and a waitlist control group of 34 elders in each group. They were assessed initially using the Pain Catastrophization Scale (Sullivan, 1995), and the WHO Well Being Scale (WHO, 1998).

* Ph. D Research Scholar, Department of Psychology, Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore

** Professor and Head, Department of Psychology, Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore

The C. A. R. E intervention was then administered over the duration of 28 sessions, four days a week for the experimental group. The assessments were repeated after the intervention. Results indicated that the C. A. R. E intervention was successful in reducing the severity of the pain and also improving the Well-being of the elders in the experimental group.

Keywords: Pain Catastrophization, Well-being, Positive Psychology, Intervention

Introduction

Old age is a period of life that brings physical ailments, pains and aches and many other issues. By the time people reach the age of 60 or 65, many of them become insecure due to loss of employment due to retirement, leading to economic dependence on their children. When this is combined with physical ailments, fatigue and exhaustion over reduced functionality, and a sense of insecurity, the problems multiply and tends to have an effect on the well-being of the elderly. An additional burden may be emotional and psychological troubles caused by family issues or illness or the loss of a spouse. All these varied issues lead to a lack of a feeling of wellness or stress, anxiety, depression and various other psychological issues. Such an influx of negativity calls for building positive thoughts and emotions to cope and strengthen their well-being. Aches and pains are a coming problem in ageing. Many times such pains are combined with worrying or rumination about the pain. This combined onslaught causes pain catastrophization. Catastrophization can be defined as, "an exaggerated negative mental set brought to bear during actual or anticipated painful experience" (Sullivan et al., 2001). This explanatory style (how one interprets and explains events to oneself) of an individual yield a clear idea of an individual's worry about the pain, accompanied by feelings of helplessness experienced or the magnification of the sensation of pain, which all leads to catastrophization of the pain. As the elderly face the pain, their mental health deteriorates and they start thinking and worrying about the pain, which in turn, intensifies the pain.

Positive Psychology is a relatively new branch of psychology founded by Martin Seligman and his colleagues. This branch of psychology postulates that the absence of negative does not ensure positive well-being. Well-being needs to be built by ensuring "Flourishing", that is, a state of mind characterised by positive emotional and social functioning. This state of flourishing that equates to a very high form of well-being can be created by deliberately focusing on constructing and maintaining positive thoughts and emotions. This paper attempts to create one such positive psychology-based intervention model to alleviate the pain catastrophization among the elderly and hence build their well-being. Applying this construct, an intervention model was constructed and named "The C. A. R. E intervention Model". C. A. R. E is an acronym that can be expanded as follows:

C: stands for Compassion and Self-Compassion

A: stands for Achieving a Purpose in Life

R: stands for Relationship Building

E: stands for Enhancing Positive Emotions

The C. A. R. E intervention consisted of activities and exercises designed to develop compassion and self-compassion, achieve a sense of purpose in life, build relationships and enhance positive emotions.

A brief review of available literature was conducted by the researchers in order to better understand the constructs taken up for study. In a study on the effect of positive psychology-based intervention modules in elderly participants, Bar-Tur (2021) developed a Mental Fitness programme and found it effective for the well being of the elderly. In a review on the effectiveness of positive psychology interventions for positive ageing, Marks (2021) reported that such interventions have the maximum effect when they are given in the residences of the elderly. It was also reported that such positive psychology applications are a cost-effective and promising means to ensure health promotion ventures for the elderly. These positive psychology interventions help to reduce the negative psychological complications associated with ageing such as depression and loneliness. Verhiel et al. (2019) in a study of the efficacy of positive psychology intervention for pain intensity and physical limitations among the elderly, reported that among all the positive psychology constructs, satisfaction with life and mindfulness played important roles. Also, skill-based interventions focusing on building mindfulness was found very effective in reducing pain intensity.

In a study on the response to the COVID crisis, Scheibe et al (2021) found that the response of the aged population was better as they used the time of crisis for personal growth. This was manifested by the better resilience scores of the older participants compared to the younger participants. An earlier study by Rowe and Kahn (2017) also reported that interventions enhance the successful ageing process as the concept of ageing is multidimensional involving physical, social and psychological domains. Reker and Wong (2012) reported that psychosocial adaptation among the elderly can be better achieved by enhancing the concept of the personal meaning of life. This concept of personal meaning is said to comprise a global meaning that is generalized and a situational meaning of life that is dynamic and changes as per situational demands. In a comparative study of self-reported well being, it was reported by Hillman (2015) that the ages 82 to 85 could have the maximum well being if they are given targeted practices to develop their character strengths and virtues. Sudha and Gayatridevi (2021) in a positive psychology-based intervention study on COVID survivors found that intervention based on compassion, achieving a purpose in life, relationship building and enhancing positive emotions are effective in reducing negative psychological complications such as depression and loneliness.

Based on the above review of literature it can be inferred that the elderly are a population that is highly vulnerable due to their physical, psychological and social decline. Positive psychology focuses on enhancing positive constructs such as happiness, optimism, hope and compassion will have an effect on a satisfied, and contented ageing process.

Method

The study on "A Positive Psychology-Based Intervention Model (C. A. R. E) for Pain Catastrophizing and Well-being among the Elderly during the pandemic: A Randomized Control Trial" was conducted with the objectives of identifying the correlation between pain catastrophization

(levels of rumination, magnification and helplessness) and well-being among the elderly and understanding the efficacy of the C. A. R. E intervention using a randomized control trial. The hypotheses framed for the study were as follows:

Ho There is no significant relationship between rumination, magnification, helplessness and well-being among the elderly

Ho There is no significant difference in the Pre-test and Post-test phases of the experimental group in the levels of rumination, magnification, helplessness and well being among the elderly

Ho There is no significant difference in the levels of rumination, magnification, helplessness and well-being of the elderly between the experimental group and the waitlist control group.

The sample consisted of 68 elderly persons both male and female who were COVID survivors selected through purposive sampling. They were then randomly assigned into an experimental group and a waitlist control group of 34 elders in each group. They were assessed initially using the:

1. The Pain Catastrophizing Scale (PCS) (Sullivan, 1995) consists of 13 items with a five-point scale and three subscales namely, rumination, magnification and helplessness. Reliability established through Cronbach alpha values is 0.87 and validity are established through construct validity. (Sullivan, 1995)
2. WHO Well Being Scale (WHO-5, 1998) consisting of 5 items measuring the well-being of an individual.

C. A. R. E Intervention Module

It includes Relaxation Exercises such as Counted Breathing, Deep Breathing, Breathing from the Stomach, and Jacobson's Progressive Muscle Relaxation (for a period of 30 to 40 minutes every day in the morning)

The C. A. R. E intervention with a sample of the activities used in the intervention is given below:

On day one, the focus of the activities was on developing Compassion. This activity required the participant to choose a kind task (Donate money/time/clothing, smile and wish someone when they least expect it, show concern to someone, give your time and pleasantness to someone from your family).

Day two consisted of activities striving to build Optimism. The participant is asked to deliberately consider an adverse event that has happened to them in the past 15 days and look at the advantages/positives deliberately hidden behind the negative emotion associated. (Examples given to the participants). They are then required to write down a thought opposed to the negative thinking associated with the adverse event.

Day three comprised of helping to build Resilience. Here, the participant must think of a stressful situation weighing them down. They are asked to write it down in detail. Also, to write down ways in which they believe they can challenge themself and bounce back from the negativity. They are asked to imagine that the stressful event is a cloud spreading over them. They are then required to break through the barrier and build on thoughts focusing on building the strength to bounce back.

Similarly, each day comprises activities to build one particular positive psychology construct. The constructs included were creating a sense of purpose, building good relationships, constructing one positive emotion of their choice, developing self-compassion, understanding and practising gratitude even for small things in life, exploring their strengths through an activity, building hope and happiness, spreading smiles, and overcoming obstacles in the path to positivity.

The sample comprised of 68 elderly persons both male and female who were COVID survivors were selected through purposive sampling. They were then randomly assigned into an experimental group and a wait-list control group of 34 elders in each group. They were assessed initially using the Pain Catastrophization Scale (Sullivan, 1995), and the WHO Well Being Scale (WHO, 1998). The C. A. R. E intervention was then administered over the duration of 28 sessions, four days a week for the experimental group. The assessments were repeated after the intervention.

Results

The data collected was analysed using the SPSS statistic version 21. Initially, the descriptive statistics were analysed.

Table 1

Mean and Standard Deviation for Rumination, Magnification, Helplessness and Well-being among the Elderly

Variables	*Mean*	*SD*	*N*
Rumination	14.71	1.67	68
Magnification	11.16	1.02	68
Helplessness	22.35	1.65	68
Well-being	35.46	11.66	68

Table 1 shows the mean and standard deviation of the variables taken up for study. The Shapiro-Wilk test of Normality was conducted to ascertain if the sample was normally distributed. The Pearson's Product Moment Correlation was computed to understand the relationship between variables.

Table 2

Correlation between Pain Catastrophization and Well-being

Variables	*N*	1	2
1. Pain Catastrophization	68	---	
2. Well-being	68	-0.25*	---

** $p < 0.05$*

Table 2 indicates that there is a significant negative correlation between pain catastrophization and well-being among the elderly. It can be interpreted that as pain catastrophization increases, the well-being decreases and vice versa. Hence, the Hypotheses, "There is no significant relationship between rumination, magnification, helplessness and well-being among the elderly" is rejected.

Paired samples t-test was conducted to understand any significant differences between the pre-test and post-test phase scores of rumination, magnification, helplessness and well-being levels of the experimental group and the control group.

Table 3

Paired Samples t-test of Rumination, Magnification, Helplessness and Well-being in the Pre-test and Post-test Phases of the C.A. R. E Intervention for Experimental Group

Pairs Variables		*Mean*	*N*	*SD*	*t*
Pair 1	Rumination pre-test Experimental Group	14.53	34	1.745	18.42**
	Rumination post-test Experimental Group	5.76	34	2.001	
Pair 2	Magnification pre-test Experimental Group	11.18	34	.999	29.09**
	Magnification post-test Experimental Group	4.32	34	1.273	
Pair 3	Helplessness pre-test Experimental Group	22.21	34	1.737	20.05**
	Helplessness post-test Experimental Group	7.53	34	3.277	
Pair 4	Well-being pre-test Experimental Group	36.03	34	12.951	9.74**
	Well-being post-test Experimental Group	64.91	34	16.101	

$^{**}p < 0.01$

Table 3 indicates that there is a significant difference between the pre-test and post-test phase scores of rumination, magnification, helplessness and well-being levels of the experimental group. The mean levels of the rumination, magnification and helplessness levels have reduced in the post-intervention phase, while the mean of the well-being levels increases in the post-intervention phase. This indicates that the C. A. R. E intervention is very effective in reducing the rumination, magnification and helplessness concepts of pain catastrophization. Also, at the same time, the C. A. R. E intervention is very effective in improving the well-being levels of the elderly.

Hence, the hypothesis, "There is no significant difference in the Pre-test and Post-test phases of the experimental group in the levels of rumination, magnification, helplessness and well being among the elderly" is rejected.

Table 4

Paired Samples t-test of Rumination, Magnification, Helplessness and Well-being in the Pre-test and post-test Phases for Waitlist Control Group

Pairs Variables		*Mean*	*N*	*SD*	*t*
Pair 1	Rumination pre-test Waitlist Control Group	14.88	34	1.591	1.47_{NS}
	Rumination post-test Waitlist Control Group	15.18	34	1.218	
Pair 2	Magnification pre-test Waitlist Control Group	11.15	34	1.048	0.52_{NS}
	Magnification post-test Waitlist Control Group	11.24	34	.987	
Pair 3	Helplessness pre-test Waitlist Control Group	22.50	34	1.562	1.29_{NS}
	Helplessness post-test Waitlist Control Group	22.88	34	1.200	
Pair 4	Well-being pre-test Waitlist Control Group	34.88	34	10.365	0.15_{NS}
	Well-being post-test Waitlist Control Group	34.97	34	9.183	

NS= Not significant

Table 4 indicates that there is no significant difference between the pre-test and post-test phase scores of rumination, magnification, helplessness and well-being levels of the waitlist control group. Independent samples t-test was conducted to understand any significant differences between the experimental and waitlist control group in the post-intervention phase.

Table 5

Independent Samples t-test of Rumination, Magnification, Helplessness and Well-being in the Post-test Phases between the Experimental Group and Waitlist Control Group

Variables	*Groups*	*Mean*	*SD*	*t*
	Experimental Group	5.76	2.001	23.43^{**}
Rumination	Waitlist Control Group	15.18	1.218	
Magnification	Experimental Group	4.32	1.273	25.03^{**}
	Waitlist Control Group	11.24	.987	
Helplessness	Experimental Group	7.53	3.277	25.64^{**}
	Waitlist Control Group	22.88	1.200	
Well-being	Experimental Group	64.91	16.101	9.42^{**}
	Waitlist Control Group	34.97	9.183	

$^{**}p < 0.01$

Table 5 shows that there is a significant difference between the post-intervention scores of rumination, magnification, helplessness and well-being between the experimental group and the waitlist control group. This indicates that the C. A. R. E Intervention is very effective in reducing the rumination, magnification, and helplessness concepts of the pain catastrophization and at the

same time also effective in improving the well-being levels of the experimental group. No such change is evident in the waitlist control group.

Hence the hypothesis, "There is no significant difference in the levels of rumination, magnification, helplessness and well-being of the elderly between the experimental group and the waitlist control group" is rejected.

Discussion

The results section above clearly indicates that the C. A. R. E intervention module is very effective in reducing the pain catastrophization levels and helps in building well-being among the elderly. Pain among the elderly is a common feature. Physical pain often manifests itself in various psychological aspects such as stress and anxiety, depression or also simply catastrophization of the pain due to high levels of worry about the pain and its intensity. Such catastrophization often has a detrimental effect on the well-being of the elderly. Positive psychology is a branch of study that focuses on building positive emotions in an effort to reduce the negative psychological effects. The C. A. R. E intervention is one such effective module that is a simple to use, time effective and user friendly intervention that helps build positive emotions, hope, savoring, gratitude, compassion, a sense of achievement of a purpose in life among many other positive psychological constructs. Similar findings were reported by a study where positive psychology interventions of gratitude and kindness building activities were given to elderly participants (above 50 years old) who suffered from arthritis. These interventions were very effective in reducing the pain intensity and also in reducing the psychological contributors to pain in the participants. (Hausmann et al. 2018).

The present study is a randomized control trial that compares the effect of the aforesaid intervention model among a randomized experimental and waitlist control group. This trial effectively establishes the validity of the intervention module taken up for study. There are a few limitations to this study as it uses a limited number of participants and tests only limited psychological issues of the elderly. Further studies using the same intervention can look to overcome these limitations.

Conclusions

The study on "A Positive Psychology-Based Intervention Model (C. A. R. E) for Pain Catastrophizing and Well-being among the Elderly during the pandemic: A Randomized Control Trial" yields the following conclusions:

- There is a significant negative relationship between pain catastrophization and well-being among the elderly. As the pain catastrophization levels increase, the well-being decreases.
- The C. A. R. E intervention module is effective in reducing pain catastrophization and increasing the well-being among the elderly as validated by the randomized control trial conducted.

The above conducted randomized control trial effectively paves the path for the C. A. R. E intervention module to be used for the reduction of negative psychological concepts and enhancing positive emotions and well-being of human beings.

7 Unconditional Self-Acceptance and Psychological Well-Being among Older Adults

Priyanga A* &
Dhivyadharshini G**

Abstract

Even though there are many factors that affects a person's psychological well being, accepting oneself as he/she is helps the individual to attain a higher psychological wellbeing in life. Accepting oneself as they are may become difficult for people as they grow older mostly depended on others, to live without their spouse and so on. Being unconditionally self accepted helps people to achieve hope, and to satisfy their own desires. Self acceptance plays a vital role in Rational Emotive Behavioral Therapy (REBT), it is not often measured in experimental manner. The current study examines how unconditional self acceptance affect psychological well being in older adults. The participants completed the Unconditional Self Acceptance Questionnaire (USAQ) by Chamberlain & Haaga, 2001, 20 items and the Ryff Psychological Well Being Scale (RPWB) 18 items. The data were collected from one hundred and thirty (130) Older adults by random sampling method. The study reveals that there is a relationship between unconditional self acceptance and psychological well being among older adults.

Keywords: Unconditional self acceptance, Psychological well being, Older adults

The unconditional self acceptance in an individual is concerned with the acceptance of one's own self without concerning other people love, respect, and approval (Hill, Hall, Appleton, & Kozub, 2008). The term unconditional self acceptance referred to things which we accept without any demand even it may be right or wrong. Self acceptance is an individual's satisfaction about himself or herself and is considered important for good mental health (Rogers, 1951; Scott, 1968). Self acceptance is a subjective measure and it may differ from individual characteristics termed as "Unique value" (English and English 1958; Jersild, 1960). This unconditional self acceptance must be noticed among older adults, where they feel inferior about their physical and the mental

* B.Sc., Psychology, Department of Psychology, Theivanai Ammal College for Women
** B.Sc., Psychology, Department of Psychology, Theivanai Ammal College for Women

abilities. The thoughts of the older adults focus on the weakness of themselves. Psychological well-being of an individual tends to be affected with the level of unconditional self acceptance of an individual. The need for the self acceptance among the elderly people is must to maintain their psychological well-being. The decrease in the psychological well-being will surely affect the person's emotional and physical well-being. In the most of the cases, the older adults will always have a conflict in accepting things as it is, where they might have any inconvenience in accepting the things. Self acceptance plays a major role in the psychological well-being because once the individual starts to accept things they will no more suffer for any reason. The unconditional self acceptance makes a positive attitude towards facing problems, especially in older adults. The unconditional self acceptance is even after having any weakness and deficiencies. Self acceptance is said to be more realistic in nature where the positive and negative concepts are taken into count.

Unconditional self acceptance

The Unconditional self acceptance is the condition which the individual accepts himself or herself in spite of having any weakness. Unconditional self acceptance includes oneself without any concern about others love, respect, and approval. Unconditional Self Acceptance is one of the determinable factors of Well-being. This makes an individual a positive approach to their life. The unconditional self acceptance is said to be more influential in all aspects of human life, especially in older age people. When the older adults develop conditional self acceptance there they may suffer from the issues of love, care and support lacking given from others. The regardless acceptance of the one's self is most important for older adults

Psychological well-being

Well being depends on both the individual and the environment, during childhood and adolescents. The psychological well-being of an individual is determined by many factors, but when it comes to older adults certain variables that affect the psychological well-being of an individual in the late age. Well being specifically relates to happiness, life satisfaction and positive affect. Psychological well being is a diverse multidimensional concept which develops through a combination of emotional regulation personality characteristics, and identity and life experience. Psychological well-being is the subjective measure the individual feelings and thoughts are valid in assessing the psychological well-being. It can be affected by many factors, social factors will mainly affect the psychological state of an individual it includes things such as what they see, what they do, where they live. All these factors influence the person's psychological well-being of older people.

Methodology

In the present study, samples from older adults in and around, Villupuram were taken

Participants, Procedure and Data collection

In this study one hundred and twenty older adults were taken taken in to count. The purpose of the study is to find the correlation between unconditional self acceptance and psychological well-being among older adults. The response for the study was collected randomly in older people in and around Villupuram, Tamilnadu.

Demographics and its measures

In the present study the participants are asked to provide the demographics information through self-reporting as part of the different questionnaire.

The unconditional self acceptance scale has 19 items with 7 point Likert scale range from 1 (almost always unture) to 7 (almost always true). The item total correlations ranged from .40 to .72

The tool used to measure psychological well-being among elderly people was Ryff's Psychological well-being scale developed by Ryff and Keyes 1995. The scale consists of 18 items rated on 7 point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). The score range of 18-126. Some questions have been reverse scored and scores represents the high and low level of psychological well-being

Statistical analyses

In the present study used the Pearson correlation coefficient to analyze the association between the scores. The statistical significance level was set at 0.05. The statistical packages used for the present study were SPSS version 26. Our independent variable was unconditional self acceptance, while psychological well-being was the dependent variable.

Results

In the present study the correlation analysis for unconditional self-acceptance and psychological well-being helps to identify the relationship between the variables.

Table 1

Correlation Statistics for Unconditional Self-acceptance and Psychological well-being

Variables	1	2
1. **Psychological wellbeing**	---	**0.206***
2. **Unconditional Self Acceptance**		

* $p < 0.05$

Discussion

In the present study table 1 shows the correlation between unconditional self acceptance and psychological well-being. A significant positive relationship was observed between the two variables stating that, as psychological well-being increases, there is an increase in unconditional self-acceptance. A number of studies have been carried out by various researchers that exhibit an inverse relationship between loneliness and psychological well-being. People who accept themselves as they are, have higher psychological wellbeing.

Conclusion

The present study examined the unconditional self acceptance and psychological well-being among older adults. The Elderly people who have good self acceptance possess good psychological

well being. The present study has revealed that when a person has higher unconditional self acceptance, then he also possess a higher amount of psychological well being. Therefore this study finds that self acceptance enhances a person's psychological well being.

Limitations

The present study shows only the correlation between unconditional self acceptance and Psychological wellbeing. But the demographics were not taken into account only the correlation study was conducted. The sample size that was taken was in a smaller size. In future to make the study much valid samples can be taken in a larger amount.

8 Correlation between Affectivity and Coping Strategies when directly Exposed to COVID-19

Dolly Rawat* &
Mansi Agarwal Riya Iyer**

Abstract

This study is conducted during a global medical crisis called COVID-19 pandemic. The pandemic was due to COVID-19 disease which was highly infectious and contagious respiratory disease by coronavirus. This study is aiming to understand the correlation between affectivity of an individual and how it affects coping mechanisms in an individual when directly exposed to the disease COVID-19. With this data we will be able to guide and spread awareness about the impact which affectivity makes under a crisis. The population selected for this study is the middle adulthood which ranges from the age 50-65 years old serving in public and were directly exposed to the corona virus. The PANAS scale and the Brief Cope Scoring were used for the purpose of data collection. Pearson Product Moment Correlation was used for the statistical analysis of the data. The findings indicate that this age group is more effectively helpful with their presence during the crisis showing higher percentage of the sample experiencing positive affect during the crisis scenario. The results also indicate positive correlation of 0.515 between Positive Affectivity and Adaptive Coping strategies which is significant at the level of 0.01. This concludes that the middle aged adults are more likely to have active and effective coping strategies encouraging volunteers amongst them for crises and their advices for action based problem focused issues.

Keywords: Pandemic, COVID-19 disease, Affectivity, Coping mechanism, Middle Aged group

The COVID-19 (Coronavirus Disease 2019) pandemic is a crisis affecting almost all the countries in the world. All the countries have tried to incorporate strategies that will help in curbing the spread of disease (Wilder-Smith & Freedman, 2020). The strategies majorly used by the countries are social isolation, which further challenges the coping capacities of an individual. Older adults was believed to be on higher risk of commuting the disease and were specifically instructed to follow social distancing (Promislow, 2020). The study focused in understanding how they coped

* Department of Psychology, Vishwakarma University, Pune, Maharashtra

in this kind of situation. At the same time it is argued that older people have more life experience as compared to the younger adults. Throughout their life experiences, they have faced personal challenges which built up their coping mechanisms (Lind et al., 2021).Younger adults are more future-oriented whereas older adults are more past oriented. This past orientation gives the older adults access to integrate all the experiences, challenges and positive coping into an acceptable whole (Webster et al., 2014). The older adults are found to have positive reminiscence style allowing remembering negative situation and how it was dealt during those situations and also remember the positive situations helping to boost their current mood(Cappeliez et al., 2008).

The positive affect amongst the older adults also further helped them in using adaptive coping strategies which further enhanced more positive affect amongst the older adults (Vahia et al., 2020). Adverse psychosocial outcomes are the result of using maladaptive coping such as escape the feeling or using avoidant strategies (Ben-Zur, 2009). A lot of researches have also found that individuals who have higher level of pandemic uncertainty were more prone to use maladaptive coping strategies (Rettie & Daniels, 2021).

Affect and Coping shows reciprocal relationship where Positive affect predisposes an individual to see stressful situation as challenging, gain learning experiences and opportunities, whereas coping process used by an individual for dealing with stressful situation leads to generate positive affect and sustaining it for longer time (Khosla, 2006) . Coping has always been studied with negative impact in stressful situation. There is a need to study positive outcomes along with coping, as positive affect also impacts coping of an individual. If utilized meaning based coping processes, it supports in enhancing positive affect during the chronic stress (Folkman & Moskowitz, 2000). Broaden-and-build theory of positive emotion was used to understand the connection of flow and affect. Flow was found to be positively correlated with positive affect and negatively correlated with negative affect. It has been predicted that an individual who uses Adaptive coping shows higher level of flow and vice versa can be found with maladaptive coping (Sophie & Giovanni, 2013).

In a research to investigate the effect of positive affect and its relationship with problem focused coping, it was found that more use of problem focused coping, and emotion focused coping along with positive affect predicted lower levels of HbA. It was also noted that Positive affect proceeded as a moderator in the use of problem focused coping strategies (Tsenkova et al., 2008). In one of the longitudinal study, it was found that people usually experiencing positive affect succeeded in showing them as stronger without frailty. This findings paved the way to positive psychology as a protective factor against physical and functional decline (Ostir et al., 2004). A study showed evidence of biological and psychological health connection with positive affect. At the biological level, individual reporting positive affect shown to be lower cortisoloutput, as well as its association with other biological markers. At the psychological level, positive affect leads to increase in social activities building social connections amongst the people. This social connection leads a person to perceive social support, have optimistic attitude and use more adaptive coping resources. Positive affect will help a person to be resilient. Aresilient person will be able to bounce in the case of adverse physical and psychological health(Steptoe et al., 2009). Positive affect and negative affect

usually co-occurs during stressful situation. Co-occurrence of positive affect may have beneficial consequences. It is also reported that positive affect interventions are easy, practicable, acceptable and effective in outcome(Moskowitz, 2011).

During COVID-19, the situation all around the world went into lockdown and social isolation. A study was done to see how elderly people cope during this situation. The findings indicated that positive refocusing and social connectedness had positive effect whereas negative emotions such as intolerance, uncertainty and loneliness affected mental health. Further it was also seen that the maladaptive strategies lead to intolerance, uncertainty, fear and loneliness whereas adaptive strategies lead to building social support from friends and positive reframing (Lábadi et al., 2022). Another study conducted during COVID-19 indicated that Positive Religious Coping predicts Positive Affect and at the same time someone with Negative Religious Coping will develop Negative Affect. Further it was also seen that the Positive affect is positively correlated with Life satisfaction (Habib et al., 2020). Another study compared the coping and positive affect between younger adults and older adults. It was found that older age could deal the scenario of COVID-19 with less concern about developing COVID-19. They showed better well-being, greater association of the situation with positive events or outcome, and ability to cope with the stressors in the environment. On the other hand, younger and middle-aged adults found it difficult to deal the COVID-19 scenario. There were more interpersonal conflicts and higher number of daily stressors in their life. (Klaiber et al., 2021).

Method

Participants

32 participants with age ranging from 50 to 65 years old were selected as the participants for this research. Random Sampling method was used for collecting the data. The data was collected with the help of Google form as well as by visiting to places following COVID norms.

Instruments

1. Brief COPE by Carver (1997) is a shorter version of the COPE. This test consists of 28-items in a form of self-report. An individual can complete the questionnaire by self-using a 4 point likert scale. The 4 point ranges from 1 = I haven't been doing this at all; 2 = I've been doing this a little bit; 3 = I've been doing this a medium amount; 4 = I've been doing this a lot. The Brief COPE measures 14 theoretically identified coping responses. Each of these 14 subscales comprises of 2 items. Every item under the particular subscale is calculated for the total scores on each of the scales. These 14 subscales are categorized into Maladaptive and Adaptive Coping. Higher score son a specific coping style indicate more use of that particular coping strategy.
2. The PANAS scale by Watson, Clark and Tellengen (1988) is a brief scale consisting of one word items i.e. the list of emotions. It is very easy to administer on any age group. This test is used for the assessment of Positive and Negative Affect. The total item scale in PANAS is 20 items with further division of 10 positive affect markers and 10 negative affect markers describing different feelings and emotions. All the items are rated on a scale ranging from

1= very slightly or not at all, to 5= extremely. Total scores are calculated by summing up the respective 10 items under positive affect and summing up 10 items under negative affect. The scores for both the domain ranges from 10 to 50. An individual scoring high on positive affect indicate a person using more of a positive affect and vice-versa. Similarly an individual scoring high on negative affect indicate more use of a negative affect and vice-versa.

Research Design

The study is a correlational study between Affectivity and Coping strategies by using Pearson Product Moment Correlation

Results and Interpretation

After the data collection process, the scoring and analysis was done. Parametric model was used for the purpose of data analysis. The results are displayed below:

The Descriptive statistics were done by calculating Mean, Standard deviation of Positive Affect, Adaptive Coping and Maladaptive Coping as shown in Table 1

Table 1

Descriptive Statistics: Mean and Standard Deviation of Positive Affect, Adaptive Coping and Maladaptive Coping

Variables	*Mean*	*SD*	*N*
Positive Affect	34.31	7.11	32
Adaptive Coping	43.53	6.20	32
Maladaptive Coping	20.94	4.28	32

Pearson product moment correlation was calculated to find the relationship between Positive Affect, Adaptive Coping and Maladaptive Coping. The correlation analysis is shown in Table 2

Table 2:

Inferential Statistics: Correlation between Positive Affect, Adaptive Coping and Maladaptive Coping

Variables	1	2	3
1. Positive Affect	---		
2. Adaptive Coping	.515**	--	
3. Maladaptive Coping	-0.120	-0.053	---

*** p< .01*

As shown in the table, it was reported that Positive Affect is positively correlated with Adaptive Coping (r =.51) and Positive Affect is negatively correlated with Maladaptive Coping with a very low correlation value (r = -.12).

Discussion

The current study gives emphasis on Positive affect developing Adaptive Coping strategies among the older adults population. Many studies reported their findings of older adults using more positive affect and its association to the use of Adaptive Coping strategies. The current study specifically focused older adult population who was directly exposed to COVID-19disease. The previous studies also supported the relationship between Positive Affect and Adaptive coping strategies. Labadi et al., (2002) stated that maladaptive strategies lead tointolerance, uncertainty, fear and loneliness whereas adaptive strategies lead to building social support from friends and positive reframing. Habib et al., (2002) stated that during COVID-19

Positive Religious Coping predicts Positive Affect and at the same time someone with Negative Religious Coping will develop Negative Affect Klaiber et al., (2021) stated that older age could deal the scenario of COVID-19 with less concern about developing COVID-19. They showed better well-being, greater association of the situation with positive events or outcome, and ability to cope with the stressors in the environment. On the other hand, younger and middle-aged adults found it difficult to deal the COVID-19 scenario. There were more interpersonal conflicts and higher number of daily stressors in their life.

Older adults are more likely to have active and effective coping strategies. They have more past experiences, more coping strategies tried and tested, and more social contacts, etc. encouraging volunteers amongst them for crises and their advices for action based problem focused issues. They are the important source of resources to access during the times of crisis. Their services and volunteer role should be encouraged and motivate participating for the betterment of the country and the world.

Conclusion

Positive Affect is found to be positively correlated with Adaptive Coping strategies amongst the middle aged adults especially the one exposed to COVID-19.

9 Resilience and Mindfulness: Concomitants of Perceived Wellbeing of Elderly

Ms. Madhuri Vaidya* &
Prof. Urmi Nanda Biswas**

Abstract

An increasing evidence suggests resilience and mindfulness contribute to wellbeing which canpromote healthy ageing. In the context of collectivist culture, family and social support play acrucial role in the resilience and mindfulness in elderly's life. Living arrangements which include the place of stay, type of family and the interpersonal relationships within the family significantly influence the psyche and the ageing process in the elderly, manifesting into their perceived wellbeing. The present research aims to find out whether resilience and mind fulness contribute to perceived wellbeing among elderly and whether living arrangements make adifference in the resilience, mindfulness and perceived wellbeing of the elderly in the Indian context. The study was carried out on 103 institutionalized and 349 non- institutionalized male and female elderly between 60 and 75 years from Mumbai and Pune city. The hypotheses, 'Resilience and mindfulness have significant effect on perceived wellbeing among elderly' and 'The institutionalized and non- institutionalized elderly will not differ in resilience,mindfulness and perceived wellbeing' and 'There will be no significant difference between males and female elderly in their resilience, mindfulness, and perceived wellbeing' were tested by using multiple regression and independent sample t test. The hypotheses were partially supported by the findings in the study; however, living arrangements were proved to be important determinant of resilience, mindfulness, and perceived wellbeing among the elderly. The implications of the research will contribute to policymaking towards healthy ageing in the Indian context.

Keywords: Resilience, Mindfulness, Perceived Wellbeing and Elderly

Introduction

The United Nations has outlined 'health and wellbeing for all' as one of the Sustainable Development Goals to build a more prosperous and secure world. The attainment of this goal will indeed navigate the process of healthy ageing to a large extent. Addressing mental health issues of elderly is one of the primary concerns to ensure healthy ageing.

Wellbeing is one of the trajectories that takes an individual towards healthy ageing (Franco et al., 2009). Healthy ageing and wellbeing are bi-directionally related. Positive ageing perceptions benefits wellbeing; however, wellbeing is one of the major contributors of healthy ageing (Cramm & Nieboer, 2018). Natural dysregulation of immune functioning in the elderly when they experience adversities on emotional and social level, challenge their coping in the context of chronic stress. Ageing interacting with stress strengthens the risk of various chronic diseases, if not mortality (Gouin, et al., 2008; Kiecolt-Glaser, 2001).

Resilience allows to develop ability to cope with the life stressors or challenges effectively. As the possibility of such experiences in various domains of life of the elderly is very high,resilience can be considered a life skill. Resilience changes the perception of illness in the adversities helps the elderly to meet challenges successfully and maintain wellbeing among them (Connor & Davidson, 2003).

Accepting every experience as it comes is considered to be a key to wellbeing in older adults;as lack of acceptance leads to despair and reduced wellbeing(Ranzijn & Luszcz, 2011).Mindfulness is non-judgmental observation of every phenomenon, which not only regulates behaviour but allows effective coping with the grieving process among elderly promoting wellbeing. One of the effective strategies needed to withstand increasingly complex and demanding world is developing life skills such as mindfulness and resilience. Mindfulness –Based Stress Reduction and mindfulness meditation are proved to be effective techniques to develop mindfulness (Kabat – Zinn, 2013).

In Indian context although the family acts as a major defense particularly in the life of elderly when he/she faces the adversity, the support available in the family does not necessarily confirm their wellbeing (Rajan & Kumar, 2003). The institutionalised elderly may enjoy social life but may be deprived of intimacy in relationships, possibly leading to loneliness and other mental health issues (Sandhyarani & Rao, 2014).

Rationale

As the population ageing is a mark of development for a nation, addressing mental health issues becomes a necessity to ensure their wellbeing. With increasing longevity and reducing fertility, independent and healthy ageing is looked upon globally. Although social and economic challenges of the elderly are aimed to be met by the policymakers, it is essential for every common man to extend the help by protecting their rights leading to healthy ageing. The past literature in the field has suggested resilience and mind fulness predict perceived wellbeing. Resilience within an individual helps develop qualities such as equanimity, perseverance, self-reliance which enhance the potential of maintaining positive adaptation in the face of adversities. Mindfulness provides powerful route for getting oneself unstuck and take charge of one's life. Implications of this

research will be useful for creating awareness about the role of such psychological constructs in healthy ageing to build a healthy society.

Objectives

1. To understand the relationship between resilience, mindfulness, and perceived well being among elderly.
2. To study the effect of resilience and mindfulness on perceived wellbeing among elderly.
3. To examine whether institutionalised elderly differ in resilience, mindfulness, and perceived wellbeing from non- institutionalised elderly.
4. To study whether there are any gender differences in resilience, mindfulness, and perceived wellbeing of the elderly.

Hypotheses

The following hypotheses are constructed based on the literature review and the above objectives -

H1. Resilience and mindfulness will significantly predict perceived wellbeing of elderly.

H0. There will be no significant difference between institutionalised and non- institutionalised elderly in their mindfulness, resilience and perceived wellbeing.

H0. There will be no significant difference between males and female elderly in their resilience,mindfulness, and perceived wellbeing.

Design

It is a survey research with correlational design.

Variables

Predictor Variables: Resilience, Mindfulness

Outcome Variable: Perceived wellbeing

Sample

The areas of Municipality of Mumbai Metropolitan and Pune city were identified.The sample comprised of 452 elderly in the age range of 60 to 70 years, randomly chosen with convenient sampling technique from selected areas of Mumbai and Pune city. Amongst them 349 male and female elderly were non-institutionalised and 103 male and female elderly were from different institutions / homes for the senior citizens in Mumbai and Pune city. Elderly without any major psychopathological problems and locomotive disability were the inclusion criteria used in the study.

Tool description

The data were collected through the standardized psychometric tools, such as -

Connor-Davidson Resilience Scale-

CD-RISC is a measure of Resilience developed by Connor and Davidson (2003) which comprises of 25 items. Each item is rated on a five-point scale (0-4), with higher scores reflecting greater

resilience. The factor analysis of the scale yielded five factors, such as Personal competence, Trust in one's instincts, Positive aspects of change & secure relationships, Control and Spiritual influences. The scale homogeneity with Cronbach alphafor the full scale is 0.89 and 0.80, 0.75, 0.74 and 0.69 for the factors 1 through 4 respectively. Test-Retest reliability was found to be 0.87. The scale proves to have a good Construct and Predictive validity, particularly on Asian population. It also distinguishes between those with greater and lesser resilience. The Cronbach alpha was found to be 0.75 for the present sample.

FFMQ-15: 15-item Five-Facet Mindfulness Questionnaire developed by Baer et al. (2008), a short form of the 39-item FFMQ self-reported measure of dispositional Mindfulness. It includes the same five facets as the long form: Observing, Describing, Acting with Awareness,Non-Judging of inner experience, and Non-Reactivity to inner experience. The test consists of 15 items on five different dimensions developed on a five-point Likert scale. Each Facet is being measured by 3 items. Gu et al. (2016) found adequate internal consistency and high convergent validity. The Cronbach alpha was found to be 0.74 for the present sample.

Subjective Well-being Inventory is a 40-item measure of feelings of well-being/ill-being asperceived by an individual in different aspects of life constructed by Nagpal & Sell in 1992. Eleven factorial dimensions of life are measured on 3-point Likert scale. The factor analysis ofthe scale showed stability in content of factors and time. The scale has 0.79 test-retest reliability with inter-rater reliability and inter-scores reliability. The scale has 0.86 validity. The Cronbach alpha was found to be 0.74 for the present sample.

Procedure

The researchers gave basic outline of the study, and an informed consent was obtained from the participant. After establishing rapport, the researchers collected demographic information with the help of a prepared questionnaire. Prevalence of any disease was noted down, if at all,with its nature, duration, frequency and intensity. The tests were administered with 10 minutes interval to avoid fatigue effect in the participant. Then the data were compiled and analysed with appropriate statistical measures.

Results and Discussion

Table 1

Prediction of Perceived Wellbeing by Resilience and Mindfulness Among Elderly

	Perceived wellbeing		
	B	**Beta**	**t**
Mindfulness	0.57	0.36	7.39**
Resilience	0.25 z	0.30	6.50**
F	136.81**		
R	0.69		
R^2	0.44		
Adjusted R^2	0.43		

**p<.01

The findings from the Table 3 of multiple regression analysis reveal that resilience, and mindfulness to be the significant predictors of perceived wellbeing among elderly. Resilience and mindfulness together cause 43% variance; none the less, each one of them is an independent predictor of the perceived wellbeing among elderly.

Resilience is a capacity to maintain or regain wellbeing during or post adversity (Whitson et al., 2016). The past research suggests that older adults are capable of developing high resilience despite the demographic factors such as socioeconomic background or poor health and benefit with lowered depression, longevity, successful ageing (MacLeod et al., 2016). Resilience has promising effects on building health and wellbeing in later years of life, particularly among the community dwellers (Lau et al., 2018).

Mindfulness is a central element in health and human services. Perceived wellbeing is enhanced through therapeutic recreation exercise of mindfulness meditation technique. It helps the individual to live more creative and meaningful life by reducing unnecessary suffering and enhanced emotional regulation (Seligman et al., 2004; Carruthers & Hood,2011). Mindfulness is effective in nurturing one's mental health and thus, enhance wellbeing (Rybak, 2013). In case of older adults facing adversity in terms of natural disasters, mindfulness helps in developing adequate psychological resources, coping styles and maintain wellbeing(Aliche & Onyishi, 2019). Mindfulness shows magical effects in rehabilitative therapy in the form of cognitive and affective benefits, significantly preventing the decline in attentional control due to ageing (Fountain-Zaragoza & Prakash, 2017), improves visuospatial attention restraining alliedage-related cognitive impairment and promotes wellbeing leading to healthy ageing (Malinowski et al., 2017).

The findings support the hypothesis 'Resilience and mindfulness and will significantly predict perceived wellbeing of elderly'.

Table 2

The Mean Differences in Resilience, Mindfulness, and Perceived Wellbeing Among Institutionalised and Non-institutionalised Young Elderly

	Institutionalised elderly (n1=103)		**Non- Institutionalised elderly (n2=349)**		**t value**
	Mean	**SD**	**Mean**	**SD**	
Mindfulness	50.86	12.23	53.43	8.66	2.38*
Resilience	64.10	21.89	69.45	17.36	2.58*
Perceived wellbeing	84.40	19.44	93.69	13.34	5.55**

*p<.05; **p<.01

The figures in Table 2 show significant difference in resilience, mindfulness, and perceived wellbeing among elderly staying at home and / institution. The non-institutionalised elderly are more mindful, resilient and thus perceive significantly higher wellbeing than the institutionalised elderly.

Although the elderly living with the spouse and children do not necessarily share a healthy relationship with their children and find them dependable (Rajan & Kumar, 2003); when the elderly are forced to be institutionalised, they feel severely socially disconnected and that affects their overall wellbeing (Sandhyarani & Rao, 2014).

In the context of collectivist cultures, living arrangements or a place of stay plays importantrole in the elderly's life, considering the family as a major social support. With reference to social exchange theory applied to ageing process, other than age and gender, contextual factors such as retirement, relocation, loss of spouse influence wellbeing, particularly among those older adults with limitations on physical mobility and independence. Living in the institution after a certain age influences the development of social exchange, as it demands adaptation on multiple levels. Positive social exchange provides tangible/intangible support and protection from stress. Companionship, presence of a spouse, children and close friends is one such support which adds to the wellbeing in later years (Wan & Antonucci, 2016).

In a longitudinal study on institutionalized and non-institutionalized adults, positive effects of both providing and receiving support on positive affect are observed only for then on institutionalized older adults (Kroemeke & Gruszczynska, 2016). Mindfulness is found to be low in the elderly from old age homes than living with the family; and mindfulness training is effective in mitigating depression amongst them (Verma & Kumar, 2019). It supports the findings of the present research and reject the hypothesis 'There will be no significant difference between institutionalised and non- institutionalised elderly in their mindfulness,resilience and perceived wellbeing'.

Older population is vulnerable to chronic illnesses, chronic respiratory problems and neurocognitive disorders like Alzheimer's disease leading to various psychological symptoms,while moderate level of clinical depression and anxiety are found to be more common(Yohannes et al., 2000; Geiger et al., 2016). Approximately 10% of institutionalised older adults suffer from anxiety disorders, majorly Generalised Anxiety Disorder in later years of life(Beekman et al., 1998; Bryant et al., 2008). Mindfulness shows significant effect of lowering depression and anxiety (Moore, 2016; Geiger et al., 2016), alleviating loneliness and promoting life satisfaction and wellbeing among older adults (Pandya, 2019).

More than 50% of the elderly sample from an old age home showed low level of resilience as againststaying with the family(Britto et al., 2020). Resilience is an effective mediating variable in a study of effect of family life on the quality of life of the Chinese older adults indicates the role of living arrangement on the resilience of elderly(Lu et al., 2017). The type of family and the family members indeed have a role to play in building resilience in individual across the life(Singh & Gupta, 2011). The findings of an explanatory study on Korean elderly revealed family support as a significant predictor of resilience other than monthly income and standard of living(Lee & Choi, 2021).

Table 3

The Mean Differences in Resilience, Mindfulness, and Perceived Wellbeing among elderly males and females

	Male (n=201)		Female (n=251)		t value
	Mean	**SD**	**Mean**	**SD**	
Mindfulness	53.55	9.98	52.29	9.33	1.38
Resilience	71.35	18.55	65.73	18.28	3.23**
Perceived wellbeing	93.42	16.36	90.10	14.50	2.29*

**p<.05, **p<.001*

The above figures show 55% of the sample are female elderly, who significantly differ from the male elderly in resilience and perceived wellbeing. The male elderly tend to perceive more wellbeing in life as well as more resilient; however, there are not gender differences seen in mind fulness.

Various demographical factors such as age, gender, and physical activity significant influence resilience among the older adults; males are found to be more resilient and physical activity is a significant mediator variable (Martínez-Moreno et al., 2020). The findings are supporting the present research. Although the culture shapes certain trends with reference to resilience and other behavioural characteristics, the results are in favour of male elderly (Fergus et al., 2020).Trauma shows its impact on individual, familial and community level. In a study done by Sambu & Mhongo (2019) on traumatised older adults, older males were found to be more resilient, who benefitted from the intervention strategies to overcome the traumatic experiences. However, contradictory findings are found by Lakomý et al. (2020), where the older women are more resilient, partly explaining the 'gender paradox'.

Women tend to live longer but with number of functional limitations, which affect manycriteria of subjective wellbeing (Carmel, 2019); reflecting in the self-reported health measures(Boerma, 2016), weaker 'will to live' and less desire to prolong life by being dependent on medication than men (Carmel, 2001). Self-acceptance, autonomy, purpose in life,environmental mastery and more importantly self-esteem and social support are the precursors of subjective wellbeing which promote successful ageing, which are found significantly higher among male old adults than females (Matud et al., 2020).

Gender differences and perceived wellbeing has been discussed ever since Wilson (1967) proposed that 'one's happiness is not related to sex'; however, the past research focuses on the 'definition' of 'perceived/ subjective wellbeing'.When the perceived wellbeing comprises of positive affect, negative affect and life satisfaction,it is imperative to comment on the gender differences with respect to these three components separately. Shmotkin (1990) claims marginal gender differences in subjective wellbeing,confirming the findings of Larsen and Stock et al. (Batz & Tay, 2018). The findings in the present study support these researches; however partially

rejecting the hypothesis 'There will be no significant difference between males and female elderly in their resilience, mindfulness,and perceived wellbeing'.

Conclusion

The present study establishes direct positive relationship between resilience mindfulness, and perceived wellbeing among elderly which implies that mindful and resilient elderly are more satisfied with their life and experience more positive emotions and less negative emotions. The research also shows a significant gender difference only in resilience and perceived wellbeing and not in mindfulness of the elderly. The findings also reveal the importance of place of stay/ the living arrangements in resilience mindfulness, and perceived wellbeing of the elderly. The elderly living with the family are significantly more resilient, mindful, experience more positive emotions, less negative emotions and overall satisfied with the life than elderly living in the institution.

Implications

The present research confirms the importance of mental health and wellbeing in healthy ageing. The findings are useful in understanding the dynamics of wellbeing among old people. The role of resilience and mindfulness in perceived wellbeing of the elderly is highlighted. It shows a need to create an awareness of enhancing the same to build a healthy society; keeping in mind the interventions are cost-effective and thus can be practiced by the elderly across the sociodemographic variables. Institutions for the elderly is recognized as a need of an hour;however, perception towards the same needs to be made positive and healthy. At the same time,these institutions should be architecture and designed to be more and more elderly-friendly. An inclusive approach towards the elderly to be necessarily practiced at societal and national level,considering psychological concomitants of healthy ageing.

10 Narrative Analysis of Adaptive Coping in Older Couples in times of COVID-19

Meenakshi Menon*

Abstract

A strengths-based lens to the process of ageing is yet to be extensively explored and studying this is vital in today's age where the proportion of the elderly is on the rise. The present study explored the strengths-based narratives of elderly couples living in isolation (empty nest) in India, in the context of the COVID-19 pandemic. In-depth qualitative narrative inquiry and analysis were used to understand the lived experiences of older couples in terms of the developmental tasks faced by them and the adaptive coping strategies employed to deal with these tasks. The study also looked to determine whether the partner's interactions with each other have an influence on the coping strategies employed by them. The emerging themes within and across the couple's life narratives pointed out to their reflections of current developmental tasks, challenges, and strengths. Current challenges in retired life were navigated through positive reframing, continued engagement in work and activities and mutual interaction. The COVID-19 pandemic and the intersectional domains of isolation associated with it had an impact on their wellbeing. The participants reported changes in routine and psychological effects arising from situations surrounding the pandemic. Emerging coping strategies, role of community and technology and shared meaning making aided in their adaptation and adjustment. This study highlights the need for a more humane, sensitive, and nuanced approach to discerning older couples functioning. Exploring these narratives in the context of India allows for a better understanding of the experiences faced by older couples in the country.

Keywords: Ageing, COVID-19, Coping, Wellbeing

* Psychotherapist and Researcher at Kaha Mind, Bangalore MA Applied Psychology, TISS Mumbai

Ageing as a construct under the critical gerontology lens not only impacts the individual but the social organization as a whole. The COVID-19 pandemic has brought about a mental health crisis in this population. As consequent lockdowns brought about a restraint in movement and travel, the activities of older adults had been constrained, further aggravating mental health challenges during the COVID-19 pandemic.

Ageing in the Modern World

According to the 'Population Projections for India and States 2011-2036' report, the proportion of older persons in the country is projected to rise from 8.4% to 14.9% by 2036. Inadequate social support, lack of adequate infrastructure, economic dependency, accessibility to healthcare is some of the important determinants of the overall quality of life of this population.

There has been a shift in the family system with the emergence of nuclear family systems in the past decades. The proportion of elderly staying alone or with a spouse has seen a stark increase from 9% in 1992 to 18.7% in 2006. This exposes the elderly population to financial, emotional, and physical difficulties.

The imperative now lies on exploring models of ageing that are sustainable, healthy, allowing the geriatric population to remain an integral part of society and enjoy a good quality of life. These initiatives must have a strong analytical understanding of the demographic factors and processes of this population, along with being pertinent to the challenges and realities of our country, rather than adopting a 'one size fits all' perspective.

Migration of Adult Children and Health of Elderly

Some of the consistent findings on research into migration of children and health of left-behind parents points out to lower levels of physical and mental functioning in the left-behind population. An elaborate review by Thapa et al (2018) found that older adults who were living by themselves had higher depressive symptoms, lower cognitive abilities, lower life satisfaction, and overall poorer psychological health. Migration has led to lower happiness and a higher probability of loneliness in older parents (Scheffel & Zhang., 2018).

COVID-19 and the Elderly

Older adults are more vulnerable and at a higher risk for developing mental health issues like stress, anxiety, and depression during the pandemic. Difficulty in accessing regular medication and routine health care along with social isolation and lack of access to technology can worsen pre-existing medical conditions in the geriatric population. These factors could result in fear of contracting the virus, panic attacks, anxiety about death, and dying or uncertainty about the future. (Banerjee, 2020).

With reduced social networks, lack of face-to-face interaction with their friends or family, this population has been experiencing depression and generalized anxiety disorders (Armitage & Nellums., 2020; Brooke & Jackson., 2020).

The changes in health-related behaviours, relationships, work, socialization, and travel as a result of the pandemic are likely to last long after the pandemic has run its course (Scott, 2020).

A study by Verhage et al. (2021) points to older adults viewing the pandemic as being ungraspable with disruptions in their daily and social lives. There is a sense of loss and lack of purpose despite keeping themselves engaged. Coping with this involved measure to decrease infection risk as a means to gain control along with applying emotion and problem focused strategies.

There is a call for brief evidence-based interventions with a focus on prevention to be explored and implemented in centres like residential complexes, nursing centres and community spaces for the elderly or through virtual mediums for those with access to technology. Developing social support systems and cognitive skills helps enable the geriatric population to experience a sense of belongingness, enhances mental wellbeing and improves social affiliation during a crisis like COVID-19 that can be an isolating experience (Mukhtar, 2020).

With reference to the way in which the elderly describes the COVID-19 pandemic, there was a gentle proposition that the situation is temporary, with regard to the coping strategies employed by this population. Considering the population's vulnerability to contracting the COVID-19 virus as well as the associated secondary physical and mental health effects of the pandemic, there is a need to have more manageable and age- responsible measures along with associated policy making and reforms directed towards the elderly.

Method

Rationale

This study is focused on the adaptive coping employed by 'left-behind' older couples in the context of the COVID-19 pandemic. This study looks to use a strengths-based approach to understand the way in which older couples respond to the developmental tasks arising from their current developmental tasks with regard to their family life cycle stage keeping in mind the contextual factor i.e., COVID-19.

- Integrating strengths-based perspective with a systemic framework.
- Isolation as an Intersectionality.
- Unfolding of the Life Story of the couple.
- Policies and Reform.

Objectives

The objectives of the study are:

- To understand the intersectional domains of isolation, and its associated challenges arising from their current developmental stage and the COVID-19 Pandemic.
- To explore the influence of the life narrative in the couple's reflections of the current developmental tasks, challenges and strengths.
- To understand their strengths in the context of the couple's shared narratives.

Research Design

A narrative inquiry using semi-structured interviews was used for this study. It allows researchers to analyse not only meanings and motives but also how people structure the flow of experience to make sense of events and actions in their lives.

Sample and Participant Profile

Four older couples were interviewed for this study. Purposive and snowball sampling was used in this study to select participants. The criteria for inclusion were: Older couples (aged 55-75 years) belonging to a middle or higher middle socioeconomic background, residing alone whose children have moved to towns/cities for education/work and visit them occasionally but the elderly couple are on their own most of the time.

Table 1

Demographic Details of the Participants

Name* (Female/Male)	Age	Birthplace	Years together	Number of children	Age of the children
Laya/Vignesh	68/75	Palakkad, Kerala/ Palakkad, Kerala	50	2	49, 47
Uma/Prakash	63/70	Chennai, Tamil Nadu/ Kolkata, West Bengal	35	2	29, 27
Asha/ Sachin	59/66	Talacherry, Kerala/ Kozhikode, Kerala	36	2	34, 27
Indira/ Sanjay	66/75	Palakkad, Kerala/ Ponnani, Kerala	45	2	44, 40

**All names of the participants have been changed to protect their confidentiality*

Method of Data Collection

The mode of the interviews were video and audio calls using an unstructured interview guide. The broad domains of inquiry included- initial life experiences, marriage, empty nest, developmental tasks, challenges as well as adaptation/adjustment in the context of COVID-19 and mutual/ interactional experiences of the couple. The language in which the interviews were conducted was English. All the interviews were recorded.

Data Analysis

The first process of data analysis was the transcription of the taped interviews. Two levels of data analysis were conducted, the first involving restorying each narrative and identifying the emerging themes in them. The second level involved identifying the common themes and categories emerging across the four stories or narratives. The thematic analysis was conducted in order to identify patterns of meaning across the raw data that helps provide an answer to the research question that is posed.

As the stories told by the four couples that were interviewed were in a nonlinear manner, moved back and forth between the past, present and future, with limited chronology, by re-storying them, a sequential link was brought about among the ideas. Clandinin and Connelly's (2000) three dimensional space approach was used for the restorying process.

In this particular study the interactional processes between the couple were explored, also taking into consideration the dialogic process between the researcher and the partners. The current as well as past stories and experiences of the couple members were looked into. The contexts in which these stories occurred, such as their home or workplace or neighbourhood are described. After the re-storying process of each couple's narrative, the themes arising from them were detailed for each of the four couple's narratives. The context of Covid served as the primary anchor in the dialogue between researcher and participants. The context of COVID-19 also brought out unique interplay of relationship dynamics in the current scenario which were otherwise hidden from view in their life narratives.

Reflexivity: The Data Collection Process and Experiences

In qualitative research, the researcher is the major instrument in data collection and analysis (Shenton, 2004). In the current study, the researcher's ideas and interests fuelled research in this topic, along with experiences and perceptions of interviewing the four couples for the study.

Due to the age and the generational gap with the participants, the researcher was very respectful of language used during the interviews. Relational terms were used to refer to the participants as it was more culturally appropriate in this space.

Results: Across Narrative Analysis

The overarching themes across the following developmental stages- childhood, marriage, child-rearing, empty nest, retirement will be highlighted. The contextual factor of COVID-19 and the emerging themes and subthemes are delved into.

Childhood

Family Background

The couple's family backgrounds had an influential role to play in the ideas, values, and morals that they built for themselves, and carried throughout their lives, spilling over into their relational spheres.

Marriage

Type of Alliance

All the four couples that were interviewed described having an arranged marriage, that was decided by their respective families. Their similar cultural and regional affinities had a strong role to play in the match.

Interpersonal Relationship

The connections, associations, and affiliations among the partners varied across the four stories. While Vignesh is more strong-headed and absolute regarding the ideas he holds, Laya is more open to change. The couple has some similar ideas on family bonding and independence of their children and emphasizes the importance that their social relationships have in their lives. Uma and Prakash have different approaches towards responding to stressful situations. Uma emphasizes the importance of open communication and is comfortable in expressing her emotions and thoughts to Prakash, whom she describes as her *"rock*". Prakash is more reserved with his emotions and doesn't express that easily. Asha is fierce in her opinions and viewpoints and put her foot down more when she wants her way. Sachin was more easy-going in nature. Sanjay and Indira continue to grow and learn from their mutual experiences, accepting change wholeheartedly.

Child rearing

Shaping Children's Future

The four couples that were interviewed had different approaches to childrearing and parenting. However, there is a commonly agreed need to shape the futures of their children and prepare them to face the outside world. There are strongly held views on the importance of quality education and a successful job, and to empower and safeguard their children through fostering their dreams and providing them the opportunity to grow.

Empty nest

Impact of Empty Nest

All the four couples interviewed express the period of empty nest as being difficult. While they were mentally prepared for their children to move out, it still seemed sudden and difficult to process. The interviewees have accepted and made meaning of these experiences in their own unique ways. They want their children to lead independent lives, with no compulsions on their children to stay back and take up the role of caretakers.

Retirement

Challenges in Retired Life

The interviewees express that retirement brought with it challenges regarding financial security, losing perks of the job, and managing the extra time available. There exists a feeling of being unwanted and forgotten, and a lack of sense of purpose. Caring for one's own aged parents brought with it its own set of challenges and difficulties.

Level of Engagement/ Activity

All four couples interviewed are continually engaging in work and activities post retirement to keep themselves occupied and physically and mentally healthy. This includes engaging in part time work, being a part of social groups and pursuing interests in nature, arts and travel. Interviewees

have also taken up childhood art forms again during this time. The partners engage together in shared interests and passions, with one of the couple's stating that they volunteer together at an NGO and enjoy traveling to offbeat locations together.

COVID-19: Impact

Changes in Routine. For Laya and Vignesh there has been an inability to travel to meet friends and family and be a part of family functions. Their children have been unable to meet them as well due to the social distancing norms in place. Due to the lack of house help, Laya has been taking over extra household chores which she says is tiresome. Uma and Prakash's plans to travel to meet their daughter had to be cancelled. The shutting down of the amenities in the apartment resulted in their activities and engagements discontinued. Asha had to stop teaching due to the closure of colleges, and this inability to tread outside was difficult for her. There was an excessive workload due to the lack of house help. For Indira and Sanjay their yearly trips to meet their children and their families, as well as their relatives, were cancelled. They stopped going on their routine walks, and also stopped meeting friends.

Psychological Impact. While Vignesh states that while at present he does not experience any challenges, he is wary about the sustained impacts on his mental health if the pandemic continues to rage on. Laya experiences fear and worry over her family's wellbeing. For Uma, the pandemic brought with it anxiety and panic attacks. As cases began being reported closer to home, there was contagion fear for the couple. The job security and wellbeing of their children was also a cause for concern. For Asha, the pandemic has been making her feel panicky, anxious, and frustrated. The inability to break the monotony and the changing circumstances have made her feel uncertain about the future. There is loneliness and strain from the added workload around the house and panic arising from the news about the pandemic. She describes the situation as "*depressing and harassing*". There is worry over her daughter's mental health. For Indira and Sanjay, the pandemic has brought with it uncertainty and fear over their health and that of their loved ones. Watching others suffer through this has been disconcerting. There is immense sadness over losing loved ones and a feeling of "*helplessness*" over the inability to go for a condolence visit. Their increased vulnerability due to their age brings fear of being dependent. Indira is also concerned about the effect that the pandemic can have on the education sector as a whole.

COVID-19: Adjustment/ Adaptation

Emerging Coping Strategies. All the couples interviewed have been following government guidelines, avoiding social gatherings, and taking all the precautionary measures. Health is an important aspect for all of them. Laya and Vignesh have changed some of their food habits with a focus on eating healthier meals, and have been keeping themselves fit by practicing yoga. Uma and Prakash have begun taking more nutrient-rich foods. Yoga and physical activities help them keep a better frame of mind. Asha and Sachin have been avoiding ordering food from outside, and have also reduced consuming unhealthy food. Indira and Sanjay keep themselves fit through yoga and consuming balanced meals.

Laya and Vignesh as well as Asha and Sachin have been avoiding misinformation from the media by following only government channels for information. Asha has been trying not to pass on

disturbing news to others. Uma has cut down her news intake and urges her husband to do the same due to the flurry of disturbing news that added to her distress.

Laya has been taking up most of the household chores. She has been connecting with friends and resuming her activities online. Uma has been reading self-help books, chanting, and meditating to keep herself centred. She has been relying on social support through her friends, and family. Prakash's analytical approach helps her balance her emotions when she experiences anxiety. Prakash has been volunteering for social causes during this time. Asha and Sachin have taken up reading and watching movies together. Both Asha and Indira mention that their husbands have begun helping them with household chores during this period. Through keeping in touch with friends and family and taking up activities like reading, Indira and Sanjay have been coping with the isolation brought about by the pandemic. The balanced approach to stress between the couple and the unexpected visit from their son and family helped them navigate some of the loneliness and stress during this period.

Role of Community. From maintaining precautionary measures to helping vulnerable populations residing in the area, the neighbourhood or communities in which the couples live have been facilitating their adaptive response to the pandemic. The communities have helped them gain a sense of safety and security, derive feelings of positivity and resilience and help them feel more in control of their surroundings.

Technology. The four couples interviewed are adapting to virtual platforms to stay in touch with their friends and family. Their activities like yoga, dance and music have shifted online. There is a reliance on online mediums to order essentials, stay connected with social groups and family. that they are a part of through technology. They are also educating themselves to use technology in order to not feel "*left behind*".

Meaning-making. Across the four narratives, the interviewees state that universality of COVID-19 has helped place the focus now on positive thought, willpower, and mental fortitude. There is a comparison with others who are facing tougher times due to COVID-19, which brings about a feeling of gratitude and privilege. The interviewees are taking precautionary measures, helping each other cope and deriving comfort in knowing the entire world was going through the same situation.

Discussion

The present study delved into the lived experiences of "left behind" older couples in the current context of COVID-19 through a life story approach. While each couple's narratives had their unique themes and subthemes, there were certain overarching themes identified across the four narratives.

Influence of the Life Narrative in the Couple's Reflections of the Current Developmental Tasks, Challenges, and Strengths

The participants have described how their mutual interactions have played a role in their response to stress over the course of their marriages, and how they impact their coping in the context of the pandemic. The partner's complementary response styles to adversity have helped them feel centred and aided in their overall coping. Open communication was stated as the key to a strong relationship.

The participants expressed that with time they were able to navigate their differences in their relationships, and in the present day have a more linear way of approaching their lives. There has been a shared meaning-making which has helped them accept and adapt to the developmental stage of an empty nest. There is an emphasis on their agency and independence from their children which is seen across the four narratives. Adler (2012) found that the themes of agency or sense of control and communion, or good relationships in life correlate with better wellbeing.

The participants state how the relationships provided them the space to grow, how it changed their worldviews for the better, and provided them with the support to navigate their careers and passions. Through shared interests, couples have been pursuing their passions during the current developmental stage and resuming activities that they left midway in their earlier stages of life.

Navigating the Intersectional Domains of Isolation on Mental and Physical Health

The social isolation during the pandemic added to the pre-existing isolation of older couples as a result of their developmental stage. There was a general sense of apprehension over the sustained impacts of the pandemic if it rages on over several months. These views are similar to those expressed by the older adults studied by Hamm et al (2020), who are concerned about the long-term physical and financial wellbeing due to the prolonged effects of the pandemic.

This physical isolation combined with the influx of negative news reports added to the worry and fear over their wellbeing and that of their loved ones. Couples reported experiencing panic and anxiety surrounding the situation. The uncertainty surrounding the COVID-19 protocols, impacts of the virus, and vulnerability of their age group to the virus added to the existing worry. Social disconnection predicted higher perceived isolation, depressive and anxiety symptoms in older adults (Sartini et al., 2020).

Navigating this isolation through the use of technology to connect with loved ones, avail resources and stay active was identified across the four narratives. They navigated grief, worry, and fear by confiding in their friends and family and deriving positives from others as well as their surroundings.

The community or neighbourhood in which the couples reside has played a significant role in helping them navigate the *"new normal"*. From helping them procure necessities to ensuring their safety and security, the community has helped alleviate some of the worry and fear associated with these times.

Staying active through physical and mental exercise was an emergent theme across the narratives. Physical exercise plays a role in delaying immunity dysfunction, promoting immune system regulation, and thus could prevent the risk of acquiring COVID-19 infection and reduce the complications of recommended self-isolation in older adults and elderly individuals (Abdelbasset, 2020).

Conclusion

The study delved into the various developmental tasks associated with old age and with the current pandemic as well as the adaptive coping mechanisms employed by the couples to respond

to them. It not only threw light into the experience faced by this population but is a step towards future research employing a strengths-based perspective to study the geriatric population.

Limitations of the Study

This study was conducted on a small population of older couples, and as in all qualitative studies, these stories are in no way representative of the larger population of the elderly. Triangulation was not included in the research design. Furthermore, all the participants of this study are fairly educated belonging to the middle or higher socioeconomic category. Therefore, the results are limited and may not reflect the experiences of older couples belonging to varied socioeconomic statuses.

As the participants were elderly, the duration of the interviews was maintained according to their comfort. Since all the four couples had such rich and detailed relational stories, it would have required much longer interviews or multiple interviews in order to understand the countless experiences across their lives.

In qualitative research, the researcher's subjectivity is unavoidable and my personal biases and assumptions could have possibly influenced the findings of the study.

Implications of the Study

This study contributes to the limited body of research focused on the geriatric population from a strengths-based lens in India. The population has been increasingly facing isolation which has magnified in the light of the current COVID-19 pandemic. While online technology could be used to provide a sense of belonging through social support networks, due to the disparity in access and digital literacy, interventions could be in the form of simple telephone contact. Community outreach programs that provide peer support or contact with healthcare professionals involving more frequent telephone interaction could be facilitated.

Through focusing on the strengths of the elderly, policies and reform can be focused on empowering and assisting this group in overcoming the challenges that are a part of their developmental stage and influenced by the current contextual factor, COVID-19.

Future Considerations

A majority of the literature available on loneliness, ageing, and COVID-19 is from the standpoint of western countries. Further research needs to be focused on the impact of the added loneliness associated with the COVID-19 pandemic in the long run for older adults residing in the Indian subcontinent.

Mental health practitioners must recognize the importance of employing nonpharmacological approaches towards enhancing resilience, and coping, and reducing loneliness in older adults. This could include using cognitive behavioural therapies, promoting compassion training, greater connectedness, and physical activity.

11 Existential Psychotherapy as an Effective Intervention for Psychological Issues in Older Females in India

Purnima Gupta*

Abstract

Can existential psychotherapy be the answer to the issues faced by the older women in India? A look at the concerns faced by the older women who have reached to the other side of their mid-lives and the question finds its answer. A careful observation of the older women in India leads to the understanding that most of these women feel a sense of emptiness. Most of their concerns are related to their self-worth or the nature of their existence during their old age. Approaching the end or culmination is never smooth for an individual. It calls for tremendous rationality, objectivity, and resilience on one's part to be able to take stock of one's life and stay hopeful despite all that has been passed. The growing age catches up with one's psychological, emotional, and physical abilities and leaves the individual with a gaping sense of worthlessness, depression, anxiety, or some other mental health issues. The problem gets aggravated in a patriarchal society like India where women usually struggle to express their valid needs and expectations. Patriarchal atmosphere leads to intense suppression in women and the impact of which becomes visible in their older years. Such women struggle with mental health issues, psychosomatic illnesses, and emotional disturbance in their lives after middle age.

As an intervention approach for the mental health challenges of Indian older women, counselling and psychotherapy have been proven effective. Out of all the available frameworks of psychotherapy, the paper is an attempt to explore existential psychotherapy as a choice of intervention for older women. The paper also explores the nature of issues experienced by older women in India.

Introduction

Middle age years begin from 45th year of life and then go till the retirement year. Middle age is usually considered a period of substantial physical, emotional and psychological changes in an individual's life. It also is understood through detailed research that women experience significant changes beginning from the onset of their menopause making the middle years a cumbersome period for them. One of the biggest challenges during the middle age years is an unintentional visit to one's past choices and decisions. As women start moving towards their old age, they uncontrollably start experiencing the urge to take stock of their years gone by. Much of their lives in the past are governed by the norms put in place through social and cultural traditions. Their persona is a representation of their adherence to social and cultural norms. But once the middle age hits, women find themselves being rendered out of demand. They are no longer sought after by their spouse and children or other family members. Most of these women find themselves experiencing a state of worthlessness, a gaping void or vacuum and a future that appears bleak. The feeling is common to almost every woman, yet the solution is far from being approached. Many women also experience psychosomatic chronic illnesses as an expression of their inner struggle, whereas some even fail to recognize and seek appropriate interventions for the same owing to their social, cultural, and demographic limitations.

During the past 2 decades, there is a rise in the number of women approaching counsellors or psychotherapists to seek help for their psychological and physical health issues. The realization of not having lived as their true self gnaws at them as they realize that their time draws closer. While all the psychotherapies prove to be effective in supporting the women in their journey of self-exploration/individuation, this paper lays emphasis upon existential technique as a tool of psychological intervention. Existential theory propounds that the task of individuation or achieving one's true potential is easy to be attained if the individual has a purpose/ meaning for one's life. This purpose is akin to being true to one's inner conviction to the life and living with an awareness of the ultimate truths about the same. The purpose acts as a ground beneath one's feet and helps the individual move beyond the everyday drudgeries of life. The existential model of psychotherapy supports the individual in excavating his core personality through various layers of conditioning and facing the subjective truth in the form of a purpose that is sacred to an individual's existence.

The existential exploration is not about analysing the everyday challenges of an individual life rather it is about an honest encounter with what it is (Frankl, 1963). It is proposed through this paper that when applied as an approach to support the middle-aged women in exploring and accepting their true self, existential model/approach can be an effective pathway.

Living and existence sound similar but they are different from each other in the way they explain an individual's pattern of life. Living is more about being fully involved in all the matters and situations of life whereas existence is more about adapting oneself to ensure smooth, non-frictional sailing from birth to death. Some philosophers may argue that existence is deeper in meaning whereas living is just going about your routine. As a researcher with a deep interest in exploring the human existence and its various facets, I look at existence as a term that carries personal value while living is more about attributing a common value to each life and certain parameters. Following my own

personal definition of existence, I am trying to explore the existence of women in India pertaining to their middle age situations and conditions. A lot has been written, researched and documented about various problems and solutions revolving around mid-life challenges for women though, yet this research paper is my sincere attempt towards all that the women contribute in their various roles so that people like me grow up to do something substantial/ follow our dreams.

My understanding of the nature of problems faced by women in their Middle Ages comes from my own observation of my surroundings and thus, forming the basis of my argument and research. Seeing women in their Middle Ages has often ignited extreme rage and helplessness, in those who possess the capacity to feel. This research paper is attempted to put my everyday observations of middle-aged women and their woes into a perspective that can lead us become more empathetic towards the existential challenges faced by the aging women in India. I also have suggested a solution in the light of existential psychotherapy, as it addresses the issues in their entirety and provides long-term solutions.

Method

This research paper is a result of literature review method after an intensive reading and reflection of the available literature and texts in the field of existential theory. The papers reviewed for the paper include both original work and review literature. Books written by the founders of existential theory were also referred for further reflections along with the available information in the form of articles and research papers on internet.

Indian Women and the Mid-life Crisis

Women in Indian culture have long been entrusted with the responsibility of nurturing and caring for their family members. There are set paths and traditions that slowly mould young girls into the future nurturers. By the time, they reach their middle age, their sense of identity majorly relies upon the relationship they share with their spouse, children, and other family members. But the scene changes with growing age and especially when the middle years of life come knocking. Middle age for Indian women is a period of transition in many ways. This specific period not only brings significant physiological changes but also demands women to adapt themselves to a life with fewer responsibilities and more time with oneself. A sense of loneliness and worthlessness also dawns upon women as their children begin to establish their own life and identity different than their parents. It is in these times that women begin to feel unworthy, unloved, and abandoned by their family members. Their social space also paints a bleak picture for them as they realize the limited existence of their social transactions. Amidst all physiological, psychological, and social transitions, the middle age transition brings a lot of challenges for women in terms of their self-worth, identity, and purpose (Sharifi et al., 2014). With new insights pouring in, women experience a need to express their concerns and be their authentic self. The stifled expressions and earlier suppressed emotions throw them into a situation where their physical health goes downhill. An outbreak of psychosomatic symptoms in the form of chronic disorders such as rheumatoid arthritis, diabetes, hypertension, knee problems, cardiac problems become synonymous to middle age years (Ahmed, 2017). Many of these problems leave these women questioning their future as they

look at a dependent life. A dual challenge in terms of changing relationship dynamics and health issues owing to ageing pushes the women to look deeply into one's inner life and face the truth. A deep sense of worthlessness and emptiness plagues the mind of these women, pushing them into a vicious cycle of self-pity and sadness. Anxiety, depression, and other such mental health disturbances appear very common in the women around their middle age years. Conventional methods of intervention rarely provide any permanent relief aggravating the whole feeling of being rendered with no hope for their future. At the bottom of such hopelessness, lies the fear of being mortal or not being in use as a human being. This feeling is the onset of what is addressed as "existential dread" or "existential anxiety" by the existential philosophers and psychologists (May, 1977). The theory of existential intervention strongly proposes that any attempt to cure the presenting symptoms (physical or psychological) must address the underlying core of one's fearfulness or disappointment with the meaninglessness or absurd nature of the existence.

Existential Approach

The discovery of one's true self has been considered the highest goal of an individual's life and almost every culture and religion encourage its followers to walk towards their true expression of the self. Since the beginning of psychotherapy as an intervention/ solution to an individual's inner struggles, has also proposed "knowing oneself" as an effective approach to the struggles. Carl Rogers, an American Psychologist, and the founder of Client-centered Therapy wrote about the concept of "Real Self" and Ideal self (Rogers, 1961). He mentioned that the more is the gap between what a human being IS and what the human being idealizes to BE, the more challenges a human being will have in his life. The authentic expression of a human being is what brings more authenticity to the expression of an individual and the same is needed for the maintenance and restoration of balance between one's physical and psychological entities/ expression.

Another important mention in terms of existential challenges is proposed by the Austrian Psychiatrist and the founder of Logotherapy Dr. Viktor Frankl- a holocaust survivor. Dr. Frankl came up with this theory that the lack of meaning for one's life is what gives rise to anxiety, feelings of worthlessness and other similar mid-life challenges (Frankl V, 1969). He proposed that finding a purpose for one's life is what keeps the individual involved with the life and motivates the individual to face the challenges with all his might and not give up easily.

Around 1970s, Dr, Irvin Yalom also proposed his theory of what an existential crisis looks alike. According to Dr. Yalom, death, isolation, meaninglessness, and freedom are the four given conditions of human life. These 4 key areas are what determines the intensity of an existential crisis for everyone.

Rollo May was one of the earliest psychotherapists in 1950s who brought the existential movement to America and said that the root cause of all the neurotic conditions is the anxiety that one experiences regarding one's own death.

All the existential concerns point out at the sense of despair, alienation, worthlessness and lack of any direction or orientation experienced by an individual. Sometimes, the presence of a chronic illness or economic challenges pushes an individual into a crisis whereas, for most of the people, the existential crisis knocks at the door when the middle age comes calling.

During the therapeutic interactions, the focus area for existential approach is the "ultimate concern about one's disappearance or mortality", which, is believed to be the chief cause of all the presenting forms of anxiety in an individual.

One's relationship with oneself is sacred to the successful implementation of existential psychotherapy. This relationship is sacred than any other relationship the individual may be having with other human individuals and with his surroundings. This existential relationship reaches far beyond the conventional take on what it means to be oneself. It is believed that coming to terms with one's past or accepting the tumultuous past that one has had will bring ultimate peace to one's present and future. The existential approach offers a different perspective and urges the individual to explore his relationship with the "ultimate givens" of life (Yalom, 1986). The approach doesn't discard the past as unimportant but proposes that the individual answer to the fundamental questions of "what it means to be born as a human" and the conditions that surround the human existence, lies in facing it all. The existential approach has been through certain makeovers in terms of what all needs to be included in the approach as a therapeutic technique. However, the essence has largely remained unchanged.

Discussion

Effective Intervention of Mid-life Crisis through Existential Psychotherapy

Living and existence sound similar but they are different from each other in the way they explain an individual's pattern of life. Living is more about being fully involved in all the matters and situations of life whereas existence is more about adapting oneself to ensure smooth, non-frictional sailing from birth to death. Some philosophers may argue that existence is deeper in meaning whereas living is just going about your routine. As a researcher with a deep interest in exploring the human existence and its various facets, I look at existence as a term that carries personal value while living is more about attributing a common value to each life. Following my own personal definition of existence, I feel compelled to propose the use of existential psychotherapy as an influential approach by mental health practitioners to support the women, particularly those in their mid-life years, in overcoming their existential woes.

Application of existential technique demands that the therapist has a deeper, clearer understanding of the nature and intensity of existential issues. Helping a client see through her anxieties and other physical as well as psychological symptoms is more than just trying to gauge the spectrum of the issue. The client is gently nudged by an existential therapist to recognize the core concern i.e., the fear of being rendered useless or the realization of having left with a limited period to accomplish the tasks/ goals set by oneself. The whole exercise of being present to one's dreadful yet faint recognition of the limitations that exist in various areas of one's life, requires tremendous patience and above all, wisdom. The therapist must be well-versed with the experience of existential challenges and the various symptoms in an individual's behaviour that signal the presence of such an existential angst.

It is imperative to note here that the deeper one dives into one's unconscious fear of death, the more one is faced by a truth about one's being just an ordinary individual with skills, talents, and

abilities common to the entire human race. The identification of one not being special is akin to facing a mirror that reflects the truth of what one is. The day-to-day failures in various actions and behaviours are nothing but a reminder of humans being ordinary. Our failures and miseries and disappointments are a stark realization of the fact that essentially, we are not in control of anything, rather we are controlled by the life.

Existential therapy is a technique to explore all such universal yet largely ignored and forgotten truths of a human life form. The gradual uncovering of all the unconscious psychological defences ignites intense fear and dread in an individual leaving him vulnerable to the ever-present challenges around. The fact that the death anxiety is the main reason beneath all the psychological and psychosomatic symptoms is a huge discovery around mental well-being. Clinical investigations done in this area have been revealing startling facts about death anxiety being the root cause of all anxieties.

It can be suggested here that women going though their mid-life crisis can be encouraged to find a solution for their issues through existential psychotherapy and overcome their existential challenges as suggested by Viktor Frankl. According to Frankl, a human being can lead a meaningful existence by dedicating herself for a cause that she believes in, an involved relationship with another human being and adopting resilience in the face of adversities. The purpose always is personal to an individual and can neither be adopted nor can it be taught. A thorough investigation into one's inner world paves the way for a woman to come out in her full glory and grow into an individuated expression of human form.

The identification of one's underlying fear of one's disappearance from the world and later, accepting one's mortality with grace and gratitude is what brings life a full circle.

Limitations and Directions for future research

The paper is written as a conceptual paper but the limited availability of writings from an eastern perspective was felt all along. The theory, its applications and the case studies all are documented from a western cultural approach, and this offers an opportunity to explore the theory from a cross-cultural perspective. Also, there is a strong recommendation to document the case studies in a detailed manner to substantiate the future research in the area of existential psychotherapy as an effective intervention technique.

Conclusion

It is concluded that the existential method can fill the gap between middle age problems experienced by Indian Women and the intervention methods used to address them. Existential method guides and supports the women in facing their true self and shed behind their external persona (developed because of socio-cultural conditioning). The techniques of existential therapy proposed by Viktor Frankl and Irvin Yalom pave the way forward to holistic well-being for women going through their mid-life crisis. A thorough exploration and later, acceptance of one's inner world is essential to find an authentic expression of oneself.

12 Ayurveda for Healthy Ageing

R. Vasumathi*

Abstract

Humans have always been looking for techniques that help delay the ageing process. With the rapid advancements in the medical field, extending an individual's lifetime through various medications is now possible Geriatrics is a separate branch in Ayurveda called as "Jara Chikitsa" which deals with prevention and cure of problems and diseases related to old age. This branch deals with the all the physical, mental and emotional ailment that develops in Vridhopacharaneeyam" (Old age)

This research paper helps to understand the steps behind ageing healthily and happily through the various techniques in Ayurveda. Etymologically the word Ayurveda is associated with a prolonged healthy life. Ayurveda advocates healthy body through a healthy mind. It clearly mentions that if there is a disturbance in the body or mind then ailment or disease becomes prevalent. Diseases manifest mainly due to the imbalance of the tridoshas or humors present inside the body. This system believes that treatment methods are different for each individual and understand the uniqueness of an individual's immune system. Ayurveda helps an individual age naturally by combining body, mind and spirit. The methods followed in Ayurveda are not just medicines or pills to stay healthy. It is a complete holistic process offering various methods and steps to age graciously, live longer and align with the environment and nature.

Introduction

Ayurveda is the mother of all healing systems. From its eight principal branches, geriatrics explains the ways and methods of healthy ageing. Ayurveda helps lead our daily life in harmony with nature and its laws. This ancient wisdom of science aims to prevent diseases or disorders and heal disorders or diseases from the sick person.

The Ayurveda system is a holistic healing system to its truest sense (Lad, 1999). In the human body, Ayurveda advocates the balance of three vital energies or dosha's, Vata, Pitta and Kapha, to help maintain good health and a healthy mind. If the human mind constantly interacts with nature, the body and mind will self-heal or stay in their best health.

Ayurveda means "the Veda or science of longevity". It is a part of Atharvana Veda. Ayurveda advocates diet, lifestyle, relaxation, rejuvenation, cleansing, kashayams, choornams and medicinal herbs. It also gives an insight into lifestyle choices (*Dinacharya*), which helps one stay healthy or unhealthy based on their choices.

Each individual has their own or unique body properties based on the composition and balance of the three doshas. Unlike modern medicine, Ayurveda prescribes medicines based on every individual body nature and composition. It considers the external environment's influence, like seasonal changes, and the changes in our emotions, diet, and lifestyle before prescribing any medications. In order to remain healthy, both our internal and external conditions should be in harmony.

If the inner doshas are unbalanced, then various ailments develop. The imbalance of *Kapha* leads to cold and cold-related sicknesses. *Vata* imbalance leads to constipation, indigestion, gastritis, arthritis and gastric based issues. Imbalance in *pitta* dosha leads to indigestion, heartburn, rashes, diarrhoea, rash and other indigestion issues. We need to balance, juggle and adjust these three doshas accordingly not to disturb our bodily or mental equilibrium as we age. To achieve this, Ayurveda shows the path and methods to age healthily.

Ayurveda makes each individual responsible for their own life as it helps the individual attain or reach the purpose of his/her life, the final salvation or spiritual liberation. This can be achieved only through good health and healthy living.

Health issues crop up when the lifestyle of the individual is not good. Stressful work, marital issues, relationship problems, and other pressures from the environment cause imbalances in the three doshas, which leads to disease or ill health.

Ageing or *Jara*, as Ayurveda defines is a natural, inevitable phenomenon like thirst and hunger. The three doshas are prominent at various stages of life. *Kapha* dominates during childhood, whereas *Pitta and Vata* dominate during middle and older.

Composition of the body according to Ayurveda

According to Ayurveda, the human body is made up of the three humors (*Pitta, Vata and Kapha*), five essential elements (Earth, Water, Fire, Air and Space), seven tissues (*Mansa, Asthi, Rasa, Meda, Shukra, Raktha and Majja*) along with the excretory products (urine, sweat and faeces). Balance in these above compositions in different proportions is unique to each human body. The

development and the balance of these compositions depend on the nutrition one absorbs from the food, which is made of the five essential elements mentioned above. The different permutations and combinations of the five essential elements lead to the humors present in the human body, which is different for each human being. When the balance or equilibrium of the doshas are lost due to internal and external reasons like erratic lifestyle, seasonal changes, dietary issues, and so on, it gives rise to disease or chronic illness, which can be cured through *Panchakarma or Rasayana treatments*. Through these treatments, Ayurveda mainly restores the balance of the humors in the body. A healthy body leads to a healthy mind. Ayurveda prescribes medications and treatments based on the illness individually rather than generic medication to all with the same illness.

Ashtanga of Ayurveda

Eight limbs or branches of Ayurveda are known as Ashtanga Ayurveda. The eight branches are exclusive or specialised uniquely. The eight angas or ashtanga are prevalent from the olden days, which shows that Ayurveda is an advanced branch of holistic medical practice.

Kaya Cikitsa (Internal Medicine): This is also like general medicine, and it helps to maintain or restore the metabolism in the body by correcting the imbalance created by Agni (*Kaya*) – the digestive fire in the body. It also deals with treating general illnesses like cough, fever, loose stools, etc.

Vrushya Cikitsa (Fertility): This branch deals with fertility and reproductive issues and helps to get good offspring. It also improves virility and sexual prowess through proper medication and therapies.

Bala Cikitsa (Paediatrics): As the name suggests, this branch deals with health and illness related to children.

Urdhwanga Cikitsa (ENT): This branch deals with the diseases that affect the parts of the body, which are above the neck, like eyes, ears, mouth, teeth, throat, nose and head.

Jara Cikitsa (Health and Longevity): This branch is mainly for longevity, good health, graceful ageing and improving the complexion, memory and immunity. It mainly deals with preventing, managing, and treating old age issues with the help of various herbs and therapies.

Damshtra Cikitsa (Toxicology): This branch deals with the study and treatment of poisoning from animals, plants, various poisons, minerals, metals, and toxic elements from all types of pollution.

Shalya Cikitsa (Surgery): This is mainly about surgical procedures like pre-operative, post-operative, anaesthesia and sutures. This branch is the treatment for diseases like tumours, fractures, plastic surgery, and many other surgical treatments.

Graha Cikitsa (Psychiatry): This deals with psychological disorders and mental health issues.

Methodology

Aims and Objectives:

The aim and objective of this study is to understand, re-assess, discuss and elaborate on health-related problems of ageing and ageing naturally with the help of Ayurveda.

Materials and Methods:

This article is based on ayurvedic textbooks like Charaka Samhita and other books that advocate the benefits of Ayurveda for healthy living and healthy ageing. This article has also referred to various websites which explain ayurvedic concepts in detail.

Geriatrics in Ayurveda (Jara or Rasayana Cikitsa):

According to Charaka, Ageing or Jara is a natural but inevitable process that is degenerative. The deteriorating changes in the body happen during the final span of life, which is called *Vriddhavastha* (Charaka Samhitha). The energy principals or doshas dominate each phase of the human life span, divided into three phases known as *Vaya* in Ayurveda. *Kapha* dominates during *Balavastha* (childhood, 0 – 16 years), *Pitta in Madhyavastha* (Youth, 16-60/70 years) and *Vata in Vriddhavastha (Jara,* Old age, 70 years and above). When these doshas are disturbed or imbalanced due to wrong nutrition choices, senses and lifestyle, it leads to early ageing and deteriorating health. Balancing these doshas bring about good health and will delay the ageing process smoother.

During *Vriddhavasatha*, due to *Vata dosha*, there will be decaying of the physical body like wrinkling the skin, greying of hair and impairments in mental and cognitive functions. When *Vata dosha* is dominant, it leads to indigestion and does not provide the required nourishment to carry the metabolic activities due to the change in the Agni, which is called *Vishamagni* (Chakrapani). Agni plays a significant role in the ageing process as the Agni (fire) helps digest food and convert the food into its nutrients.

Ageing, as per Charaka, can be classified into two types: timely ageing *(Kala Jara)* and untimely ageing *(Akala Jara)*. Timely ageing is ageing at the appropriate age of 70 years (Charaka Samhita), whereas untimely ageing happens due to the aggravation of *Kapha and Pitta* doshas during young age. Various reasons like lifestyle issues, diet, sleep and so on are the reasons for this untimely ageing.

Jaravadhana Poshana

Modern medicine speaks a lot about the aetiology of ageing and how to prevent early ageing and to age healthily. It mentions the ageing process as a slow, continuous and insidious destruction in the structure and metabolic activities of the human being after attaining sexual maturity. However, in Ayurveda, a separate branch is dedicated to *Jaravadhana Poshana* (Healthy Aging). The natural ageing process is uniquely different for each person (Brahmanand et al., 1999).

Preventive health care is the chief aim of Ayurveda. The chief perspective of Ayurveda is to delay natural ageing (*Kala-Jara*) and prevent Premature ageing (*Akala-Jara*). From its extensive methods, Ayurveda advocates *kaashayams, Dinacharya (*daily regimen*), Panchakarma techniques (*removing toxins from the body*),* palliation and pacification *(shamanam),* wholesome diet *(Hitakara and Matravata ahara), therapies and Rasayana* care to combat premature ageing and help in healthy ageing.

Prevention of premature ageing and Healthy Aging

Ayurveda guides for preventing premature ageing and help for healthy ageing. The process of ageing rests with the correct diet and lifestyle. Untimely ageing can be prevented through following the regular routines mentioned in Ayurveda.

Regular routines

Dinacharya (Daily Regime)

Ayurveda highlights the importance of cleaning the senses, namely *Jnana* (Wisdom – five sensory organs), *Karma* (Action – five motor organs) and *Manas*, which help the soul to discover the secret of healing. Dinacharya helps to keep these five senses and mind clean. *Mahatriphala ghritam, Anjana, trataka and Netra bhasti* for eye treatment*, Karnapurana* for ears*, Nasya, Jalneti and Neti pot* for nose*,* oil pulling*, Gandusha* for mouth and *Abhyanga and Shiro Abhyanga* for body and head all helps to balance the doshas and thereby to delay untimely ageing. Excretion or removal of unwanted or toxic materials from the body is also considered an essential daily ritual in Ayurveda. It suggests removing the waste from the body as soon as possible in the morning. The domination of the doshas determines the quantity, quality and frequency of the bowel movements (Bhattacharya. B, 2011). The *purisha pariksha and muthra pariksha,* in Ayurveda*,* explain the observation of the faeces and urine in detail.

Ratricharya (Night Routines)

Ayurveda advocates good sleep for healthy ageing as sleeplessness or insomnia can lead to many chronic illnesses and cognitive impairments. It recommends ending the day with meditation, gratitude and conscious recalling of the day for peaceful *Nidra yoga*. Charaka Samhita advocates understanding and following the circadian rhythm through simple ayurvedic principles to increase longevity and age healthily**.**

Ritucharya (Seasonal Routines)

Being a system of natural medicine, Ayurveda helps to understand the seasonal changes and their effects on the bodily doshas and indriyas. Thus, maintaining a seasonal regime is essential as it aids in healthy ageing and living in harmony with the environment and the surroundings.

Vyayam (Exercise)

"*Laghavam-karmasamarthyam-dipto-agnirmedasah:-ksaya:1*

Vibhaktaghanagatratvam-vyayamadupajayate" – Ashtanga Hrdayam – Sutra-sthana;; Chaper 2, Sloka 11

"This sloka explains that the practice of physical exercise renders the body light and efficient in activities, improves digestive power, decreases obesity, and renders finely chiselled contours and consistency in body structure". (Dr. Bhattacharya. B, 2015). Thus regular gentle exercising helps balance all three doshas and increases neuroplasticity and memory.

Diet and Nutrition

Every organ works in conjunction with the biological clock and the doshic clock. Diet is explained in great detail in Ayurveda. Ayurveda books like Charaka Samhitha, Ashtanga Hridhaya, and Susrutha Samhita have detailed diet and nutrition. They explain daily diets, seasonal diets, incompatible foods, food that creates balance to the tridoshas and diet that needs to be taken at various stages in human life. Food is divided into three types *Sathvik food, Rajasic food and tamasik*

*food***,** as they have a close relationship with the three *Gunas and tridoshas***.** *Sathvik* food is light and easily digestible is usually recommended during the *Vriddhavasatha*. *Rajasic* foods are hot and spicy and increase agitation, hate, anger and temptation in the minds. *Tamasic* food leads to a lazy, lethargic and dull mind.

Good nutrition helps to improve the *Ojas* (immunity), *Varna* (Complexion) and *Bala* (Strength). The importance is given to the ideal diet that will protect the *Jatharagni*(digestive fire), prevents *Ama* (toxic, foul-smelling undigested food particles), and increase *Dhatwagni*. When the *Jatharagni and Dhatwagni* are regulated, it significantly impacts healthy ageing. A well balanced *Sattvik* diet should include carbohydrates (*Shastik and Shali rice*), Grams (*Mudga*), rock salt (*Saindhava*), *Amlaki, Gritham* (ghee), *Madhuram*(honey), fruits, milk products, nuts and minimum fats. (Chowdhury et al., 2014)

Rejuvenation and Rasayana Therapies

Ayurvedic *rasayanams* bring longevity and renewal to the cells as they give strength, vitality, and longevity, strengthen the tone, increase energy and build immunity (Lad. V, 1999). *Panchakarma purification* also helps rejuvenate, detoxify, and rebuild worn-out cells and tissues, thereby curing chronic and degenerative disorders. It also helps in healthy ageing and avoiding premature ageing through the circulation of blood and helps in preventing persistent ailments as well. Charaka identified a specialized rasayana medicine called Vayasthapana which is list of ten drug which helps to increase life span and decrease untimely ageing (Wajpeyi, S.M., 2017). *Nithya Rasayanas* (Daily rasayanas) like *Chyawanprash, Triphala and Amruth* boosts the immune system if taken regularly.

Abhyanga

Doing regular *abhyanga* or oil massage with warm oil will help maintain good health and restore the balance of tridoshas, enhancing healthy ageing and longevity.

Yoga, Pranayama and Meditation

Ayurveda recommends yoga practices as it increases the flexibility of the joints and aids in digestion and sound sleep. Yoga also helps ease menopause-related transitions, and ayurvedic herbs and therapies—meditation and *Pranayam*a help to harmonise the body, mind and soul. Meditation helps in fighting modern-day illnesses like stress, depression and anxiety. Ayurveda recommends meditation every morning or before sleeping to relax the nerves and be healthy. *Prana* means life, and the art of breathing is taught through Pranayama, which bridges the balance of the body and mind and consciousness. "*Ayurveda says that breathing is the physical part of thinking and thinking is the psychological part of breathing*" (Lad, 1999). One can lead a happy, blissful, and healthy life by controlling one's breath.

Dharma and Sadvritta:

The dharma explained through Vedas, *Sanadhana Dharma,* understands and explains the nature of laws through various scriptures and textbooks. It refers to the eternal dharma and follows the way of truth and cosmic order, which has neither beginning nor end nor limits or boundaries. (Bhattachary. B, 2011). Ayurveda follows the philosophy of *Sanadhana Dharma* with a view of

aligning the prevention and curing properties with nature. It advocates being honest and speaking the truth, and understanding the subtle messages the body communicates. Ayurveda approves that the physical urges should be expressed, whereas the mental urges should be subdued. This m*anasika vegas,* or the expression of these mental urges, leads to seven deadly sins mentioned in the *Sanadhana Dharma* due to the lack of control of the mind. To overcome this, Ayurveda advocates being sensitive to the environment, being in touch with nature, and understanding and loving oneself and others unconditionally.

Discussion

Ageing is considered a disease, and it is tried best to avoid or delay it. Ayurveda is a medical science that recommends measures to prevent premature ageing, slow down the ageing process, manage this period by palliative treatment, and treat *Vriddhavastha* as prescribed in the Ayurvedic texts. *Vriddhavastha*, according to Ayurveda, is identified as a natural process of change that happens inside the body, which can be intervened with healthy lifestyles and proper routines. Untimely ageing (*Akala Jara)* or unhealthy ageing can be avoided with the help of nutritional diets, rasayana therapies, following regular routines like *dinacharya, rathricharya and ritucharya,* meditation and yoga. When a person follows the principles of Ayurveda through simple home remedies, and with the help of proper ayurvedic practitioners, ageing naturally (*Kala Jara)* and healthily is still possible. With the current age, man has lost his connection with nature, and the interpersonal relationship has gone for a toss. There are few superfoods like *Ashwagandha, amla, Guduchi, ginseng, Basil, turmeric, methi seeds, guggul, fennel seeds and sesame seeds* to help in anti-ageing and avoid the physical and mental changes accompanied during the ageing process. (Wajpeyi, 2017).

Conclusion

Right from the age of Mahabharata, stories to delay or stop ageing (*Story of King Yayadi*) had been present to exhibit the human's desire to conquer the concept of ageing. Modern medical science, with its advancement, has increased the longevity of humans, but when it comes to the question of ageing healthily and ageing at the right time, only Ayurveda has the key to the solution. Ayurveda helps prevent and manage old age-related issues and illnesses as it is a holistic ancient medicinal science. When a person chooses to follow ayurvedic principles and techniques from his *Madhyavastha* (late adolescent or early adult stages), he can avoid premature ageing (Akala Jara) and age naturally and healthily. Thus Ayurveda helps prevent and decrease the harshness of old age disorders and age gracefully.

13 Relationship Between Functional Digital Skills and Anxiety in Geriatric Population During the COVID-19 Pandemic

Samreen K. Ahuja*
Dr. Ganesh Kumar .J**

Abstract

Since its onset, the COVID-19 pandemic has made a widespread impact on the lives of people across the world. While recurrent lockdowns and protracted restrictions may have helped reduce the spread of the virus, the adverse effects on the economy, the reduced access to healthcare facilities and the strict quarantine protocols have negatively affected the physical, psychological and social health of people and raised anxiety to unprecedented levels. To mitigate this anxiety, Information & Communication Technology (ICT) has been used to provide digital solutions for many day-to-day activities which cannot be performed physically. This has forced people to adopt new technologies to carry out routine tasks and counter loneliness and social isolation caused by restrictions. However, elderly people, who have been affected the most by both the pandemic as well as the associated confinement, are also the most ill-equipped to make use of ICT because of lack of access and the necessary skills. Thus, the COVID-19 pandemic has left a large majority of the elderly suffering from high levels of anxiety as they do not have the Functional Digital Skills (FDS) to use the digital alternatives put in place to help them. The objective of the present research was to analyse the relationship between the level FDS and the level of anxiety in geriatric population during the COVID-19 pandemic. The levels of FDS and anxiety were assessed in elderly adults visiting COVID-19 vaccination centres based on questionnaires filled by them. Statistical analysis revealed a moderate degree of negative correlation between the levels of FDS and the levels of anxiety.

Keywords: COVID-19, Pandemic, Digital divide, Digital skills, Elderly

* B.Sc Honours 2nd year, Department of Psychology, Christ University, Bangalore.

** Assistant Professor, Department of Psychology, Christ University, Bangalore

Introduction

COVID-19 pandemic has afflicted close to 400 million throughout the world, with nearly 6 million succumbing to the disease (World Health Organization, 2020). The restrictive measures like the suspension of non-essential activities, restrictions on gatherings and lockdowns forcing people, especially those over 60 years, to remain indoors to check the spread of the disease have in turn created a whole set of problems not directly related to the virus itself. While the threat of infection is producing fear and anxiety in the minds of people, closure of workplaces, interruption of exercise schedules, and extended quarantines are adding to the anxiety and posing a threat to the physical and mental health of people already under stress. Studies have documented depression, stress and anxiety as the psychological effects of the pandemic and the lockdowns (Cao et al., 2020; Rajkumar, 2020).

Cumulative data shows that approximately 74% of the deaths due to COVID-19 occur in the age group of 65 years and above (National Center for Health Statistics, 2020). Because the elderly are more vulnerable, restrictive measures have been stricter for them. This implies that the elderly are likely more affected by the restrictions as well (Armitage & Nellums, 2020). While social isolation negatively affects individuals of all ages, it affects older people much more (Jaarsveld, 2020). Social isolation often leads to loneliness and depression in elderly adults.

To mitigate the challenges posed by the restrictive measures alternatives digital mechanisms have been put in place to carry out essential activities (Jaarsveld, 2020). Online banking and shopping have enabled people to carry on their day-to-day activities without stepping out of their homes. Digital technology has enabled people to socialize with family and friends virtually to counter the negative effects of extended isolation and loneliness. Online education has helped to keep student education on track. Telemedicine has made physical and mental healthcare available online.

The elderly too have been forced to adopt new Information and Communication Technologies (ICT) to carry out their routine tasks and to counter loneliness and social isolation caused by the lockdowns. While ICT may have alleviated the negative impacts of the pandemic in the younger population to some extent, the situation in the geriatric population is different. The elderly often are less affluent with limited access to the digital technologies, may have co-morbidities and are usually quite aloof from digital services (Nair et al., 2020). Even when digital services are available, it is not easy for the elderly to adopt them for want of necessary skills Fisher, 2000).

Aims

This study aimed to examine the relationship between the level FDS and the level of anxiety in the geriatric population during the COVID-19 pandemic. We hypothesized that the elderly adults with lower levels of FDS tend to have higher levels of anxiety during the on-going pandemic.

Theoretical Background

The digital divide refers to the disparity in access to new technology which exists between different groups of people (Jaarsveld, 2020). In addition to the divide based on uneven material access to technology, it exists on three more levels - based on uneven motivation to use technology, uneven

distribution of technological skills and uneven ability to make use of technology (Jaarsveld, 2020). In the elderly population it may exist at all the four levels. The elderly not only have less access to technology, but also have less digital skills and motivation so that they end up making limited use of technology. The reasons for this are the changes that are present at the physical, emotional and social level (Iancu & Iancu, 2017). Vision, speech, and hearing may diminish with age. With advancing age in adults, responses to stimuli become slower and time taken to learn new skills increases. This potentially decreases the ability of elderly to adopt new technology (Nair et al., 2020). At the social level, there may be a decrease in income and isolation. These changes may lead to emotional issues like loneliness and anxiety of becoming dependent on others (Iancu & Iancu, 2017).

The COVID-19 pandemic has changed the way people use technology. The elderly, who lack Functional Digital Skills (FDS), are likely more susceptible to the negative psychological effects of the pandemic and social isolation. This underlines the need to bridge the digital divide in the elderly population, in order to mitigate the negative effects on this vulnerable section of the society (Jaarsveld, 2020).

Review of literature

Yang et al. (2020) identified elderly as being more vulnerable to the effect of the COVID-19 pandemic on mental being in view of the high incidence of pre-existing symptoms of depression in older adults and inadequate access to mental health services available to them (Yang et al., 2020). Armitage R and Nellums LB noted that social isolation makes the elderly more vulnerable to depression and anxiety (Armitage & Nellums, 2020). However, a cross-sectional study conducted by Das et al on psychological health in the elderly during the COVID-19 pandemic found lower levels of anxiety and depression in the geriatric population. They concluded that this may be due to the support of family members and the greater resilience among the older adults (Das et al., 2021).

Jaarsveld (2020) described how technology has been adapted to provide digital alternatives for performing day-to-day tasks no longer possible in the physical mode and for countering loneliness due to social isolation. Lima et al. (2020) underlined the need to use telemedicine for mental health care during the pandemic.

Friemel (2016) drew attention to the 'grey divide', among elderly (Friemel, 2016). Nair et al. (2020) observed that in India only about 47% of the mobile phone users use smartphones, while 53% are still on feature phones (Nair et al., 2020). A study by Lam et al. (2020) showed that about 40% of the elderly population lacked the skills to effectively use telemedicine Niehaves and Plattfaut (2010) highlighted the fact that a significant segment of the elderly population is largely excluded from the benefits of internet usage Dijk (2006) elaborated (2006) elaborated the reasons for this as lack of access, motivation and skills and infrequent usage Martínez-Alcalá CI et al. (2021) while noting that COVID-19 has forced older adults to adopt digital technologies, underlined that Digital Literacy is essential for all those left out of the digital transformation.

To our knowledge, no quantitative study to date has examined the relationship between the level FDS and the level of anxiety in the elderly population during the COVID-19 pandemic.

Method

The study was conducted using a quantitative research approach with non-experimental survey design.

Sampling

The data was collected through a questionnaire using purposive sampling technique from elderly subjects visiting 3 randomly selected COVID-19 vaccination centres in New Delhi. The data was collected over 15 days from 30 January, 2022 to 13 February, 2022.

Inclusion criteria

Elderly people aged over 65 years and agreeing to participate in the study

Exclusion criteria

Persons with past history any psychiatric disorder were excluded from the study.

Age

75% of the respondents were between 65 and 74 yr., 22% between 75 and 84 years and 3% were 85 years old or more.

Gender

62% of the respondents were males and 38% were females.

Education

32% of the respondents had education up to the undergraduate level, 20% till secondary school level, 14% till high school level, 12% till postgraduate level, 8% till primary level, 2% till doctorate level and 12% had had no formal education.

Procedure

Participants were explained about the background and the objectives of the study. They were also assured about the confidentiality of their data and informed consent was obtained.

Questionnaire

The questionnaire consisted of 29 questions. Q1 – 3 were general questions. Q4-6 pertained to demographic data. Q 7-9 assessed digital resources available (internet access, type of digital device available). Q 10 - 22 were designed to assess Functional Digital Skills (FDS). Q 23 – 29 were the 7 questions of GAD-7 screening tool (20).

To assess the digital skills of the participants we devised a simplified Functional Digital Skills Scale adapted from 'Digital Skills Questionnaire' developed by AAL Association (Active and Assisted

Living Programme, 2017). It assessed the participants for 13 FDS required to carry out day-to-day activities digitally – making voice call, sending message using a messaging service, making video call, searching for information online, reading emails, sending emails, filling online forms, interacting digitally with government departments, using mobile / internet banking, shopping online, using Telemedicine, playing music, videos or games on a digital device and downloading apps to a digital device. It is based on questions that are easy to understand and therefore, it is easy to administer to older adults. For each 'Yes' answer pertaining to these skills a score of 1 was awarded. A score of 0 was awarded if the answer was 'No' or 'I do not understand what you mean by that'. The total number of 'Yes' answers gave the Functional Digital Skills Score (FDSS).

The anxiety levels were assessed using the well-validated Generalized Anxiety Disorder Scale (GAD-7) (Spitzer et al., 2006). The GAD-7 comprises seven questions based on seven core symptoms of anxiety. Respondents record their symptoms based on a 4-item Likert rating scale ranging from 0 (not at all) to 3 (almost every day), such that the total score ranges from 0 to 21.

Results

A total of 105 subjects were requested to fill the questionnaire. Four of them refused to participate in the study. One participant was excluded on account of being under treatment for depression, leaving a final sample of 100 participants.

Statistical analysis

The collected data were analyzed using SPSS version 21.0. Mann–Whitney U–and Chi-Square tests were used to explore the significance of associations of internet access and smart device ownership with the anxiety levels. A p value of <0.05 was considered to be statistically significant. To assess the relationship between FDSS and levels of anxiety, we applied Spearman's coefficient of correlation.

Levels of anxiety

On GAD-7 Scale, scores of more than 10, indicating moderate to severe anxiety were present in 28% of subjects.

Table 1: Shows the Detailed Levels of Anxiety Among Respondents

Number of subjects with different anxiety levels (n = 100)		
Anxiety Level	**Number**	**Percentage**
Minimal	56	56
Mild	16	16
Moderate	14	14
Severe	14	14

Of the 100 subjects, 30 (30%) had no symptoms of anxiety, whereas subjects with mild, moderate, and severe anxiety were 16%, 14%, and 14%, respectively.

Digital Access

8% of the respondents did not have any phone, 26% had only a feature phone and 66% had a smartphone or other smart device. Statistically significant correlation was found between not owning a smart device and presence of GAD (GAD-7 score ≥ 10) (p=.012) (Table 2). Those without a smartphone device showed a 2.6 times greater chance of having GAD than those who with.

18% of the respondents did not have internet access. Statistically significant correlation was found between not having internet access and presence of GAD (p=0.016) (Table 2).They showed a 2.5 times greater chance of having Generalized Anxiety Disorder than those who had internet access.

Table 2

Association of Access to Technology and Anxiety (GAD-7 Score > 10)

Variable	Frequency (%)	Mean	Std. Deviation	Mann-Whitney Test (Sig.)	Pearson Chi-Square Test

FDSS

The average Functional Digital Skills Score was 4.96 on a scale of 0-13. There was a moderate statistically significant inverse correlation between FDSS and GAD-7 score (r= -0.341, p=0.001) (Table 3). Participants, who were less proficient in Functional Digital Skills, displayed higher levels of anxiety.

Discussion

The present study explored the relationship between the levels of Functional Digital Skills possessed by the elderly for carrying out day-to-day activities and their anxiety levels during the COVID-19 pandemic.

In a study on anxiety and depression in older adults due to COVID-19 pandemic in Chandigarh the percentage of elderly with anxiety was 8.7% (Armitage & Nellums, 2020). In another study on the effects of COVID-19 lockdown on the psychosocial health of elderly population in Kerala, 37.9% of the elderly showed significant anxiety symptoms (Balasundaram et al., 2020). In our study 28% of the elderly showed moderate to severe levels of anxiety, which correlates well with other studies.

Among the study participants, 34% either did not have a smartphone or other digital device. 19% did not have access to the internet. Univariate analysis showed that those who did not have access to a smart device had 2.6 higher the risk of having GAD, while for those who did not have access to the internet the risk was 2.5 times higher. There was found to be moderate negative correlation between the levels of FDS and the levels of anxiety. This is quite understandable as people with low levels of FDS or lack of access to digital resources cannot make full use of the digital solutions available to interact with family and friends digitally, to seek medical and psychological support virtually or to perform on digital platforms day-to-day activities like banking or shopping, which may not be possible physically during lockdowns, which adds to their anxiety.

While there have been many studies documenting the low levels of digital literacy among the elderly (Agewell Foundation, 2017; National Academies Press, 2000) and high levels of anxiety among elders during the COVID-19 pandemic (Balasundaram et al., 2020; Ho et al., 2020), few quantitative studies has been conducted so far to establish a statistical correlation between the levels of digital skills and of anxiety in the elderly during the pandemic. Our hypothesis posited that the elderly adults with lower levels of Functional Digital Skills tend to have higher levels of anxiety during the on-going pandemic. The results of this study corroborated this. Hence our hypothesis was proved.

While this study reiterates that digital literacy among the elderly is a necessity during the pandemic, it will continue to be in the future as well. Government agencies, NGOs and businesses must get together to ensure that elderly have access to affordable devices and connectivity and elderly friendly software and hardware. Family members and volunteers must support the elderly through training and hand holding to enable them to handle digital technology independently.

Limitations and Directions for Future Research

The study has some limitations like the small sample size, which reduces the statistical power. Although in this study the Functional Digital Skills Scale was used to assess the digital skills for the sake of its simplicity and easy comprehension by the elderly, it has not been validated. The Functional Digital Skills Score is only indicative and may not provide absolute digital skills values, but we believe it represents functional indication of the competencies of the elderly required for carrying out day-to-day activities digitally. Apart from digital skills, other factors affecting the level of anxiety like the presence of comorbidities, family support, economic status etc. were not

studied in the current research. Further studies with larger sample sizes and including the above factors may be needed in the future to conclusively establish the relationship between Functional Digital Skills and anxiety in the elderly even after the current pandemic is over.

Conclusion

Lower levels of functional digitals skills are moderately correlated with higher levels of anxiety in elderly adults during the COVID-19 pandemic. Not owning a smart digital device and lack of internet access are significantly associated with GAD in the elderly during the on-going pandemic. Bridging the digital divide among the elderly is the need of the hour.

14 Understanding Implications of Comorbidity of Major Depressive Disorder and Conversion Disorder/Functional Neurological Symptom Disorder: A Case Study with the Elderly

Shraddha J Kamble* & Dr. Pooja Rai**

Abstract

Major Depressive Disorder is a common mood disorder which leads to a wide range of emotional and physical problems as well as reducing an individual's ability to perform tasks. At times, symptoms of depression can become so severe that they impact person's life to the point where they commit suicide or attempt suicide. The most prevalent psychological comorbidities with depression are anxiety disorder, personality disorders, Obsessive Compulsive disorder, somatic symptom disorder and functional neurological symptom disorder. The purpose of the study is to understand the implications of comorbidity of major depression disorder in elderly. In the present case study of 65y/o female who has complaints of feelings of sadness, loss of interest in household work, difficulty in sleep, loss of appetite and she also has suicidal ideations, along with the complaint of feeling tingling sensations in hand and neck with constant headache. Patient also had a complaint of left side body ache. The single-subject case study design was used. The detailed case history was explored and a mental status examination was administered on the patient to make an accurate diagnosis. Patient is under the impression of major depression disorder with conversion disorder/functional neurological disorder. In order to relieve the symptoms, treatment plans utilized for the patient are psychopharmacology and psychotherapy.

Keywords: *Major Depressive Disorder, Conversion Disorder, Comorbidity, Symptoms, Diagnosis, Elderly*

Introduction

Major Depressive Disorder (MDD) is known as a common mood disorder and a significant mental disease that has an adverse effect on an individual's way of thinking, feeling and behavior. It can result in a wide range of emotional and physical difficulties as well as reducing one's capability to operate at work or home settings. Females are found more prone towards depression than males. There are other types of depression namely Disruptive Mood Dysregulation Disorder (DMDD), Major Depressive Disorder (MDD), Bipolar and related Disorders, Persistent Depressive Disorder (Dysthymia), Premenstrual Dysphoric disorder (PMDD), Depression related to another medical condition, Substance/Medicine Induced Depression Disorder, Other specified Depressive Disorder and Unspecified Depressive Disorder (American Psychiatric Association, 2013). Sad mood, difficulty concentrating and making decisions, anxiety, loss of sleep, fatigue and suicidal ideations are the most common symptoms of Major Depressive Disorder.

The Greek physician Hippocrates, the father of modern medicine suggested a theory in 4th century BC that human emotions mainly had physiological foundation and differences were due specifically to fluctuations in bodily fluids called "humors". And these humors were called yellow bile, black bile, phlegm, and blood. In Greek dialect, the meaning of the term "Melancholy" is black bile. Hippocrates theory of melancholy proposed that imbalance between these bodily fluids lead to emotional disturbances. He classified mental illnesses in three different categories that mainly encompasses mania, melancholia(depression) and phrenitis (brain fever). It's from this perception of melancholia that our current view of depression ultimately evolved. Subsequently, Greek philosopher and physician Galen expanded upon the Hippocrates theory by pointing out that personality types resulted from an excess of one of these four fluids.

During the late 19th century, a Prominent German psychiatrist named "Emil Kraepelin'' made a significant contribution to the understanding of mental illnesses using natural scientific notions. Kraepelin introduced a binary approach toward mental illness, he separated depression into two distinct forms: dementia praecox and manic depression. He pointed out that 'dementia praecox' is an organic disease caused by anatomical or toxic processes. Whereas, he believed "manic depression" as an episodic condition which does not result in long-term brain damage (Ebert, A., & Bär, K. J., 2010). The two primary classification manuals, the International Classification of Diseases (WHO) and the American Psychological Association's DSM-Classification, have relied on Kraepelin's concept until now. (K Haddad et al., 2008) Later, Sigmund Freud, the father of psychoanalysis, elaborated his view stating that depression is a result of an individual's retaliation towards an event of a loss, where the individual attributes the lost object as a way of belonging to it.

Today, the diagnosis of Major Depressive Disorder is conducted on the basis of International Statistical Classification of Diseases and Health Related Problems (ICD-10 depression criteria) and Diagnostic and Statistical Manual of Mental Disorders fifth Edition Classification system (DSM-V). Fatigue, impaired concentration, weight gain/loss, low mood, sleeplessness, loss of interest, feelings of worthlessness, psychomotor agitation, and recurring thoughts of death or suicidal ideation are all diagnostic criteria for major depressive disorder, according to the DSM-V

system. Five or more symptoms out of nine should be present for a diagnosis of Major depressive disorder (MDD). Whereas, in the ICD-10 system core symptoms include depressed mood or persistent sadness, lack of pleasure or interest, lack of energy or experiencing fatigue. And out of ten symptoms, at least 4 or more symptoms are required for making diagnosis and formulating treatment (Ijaz & Saqeeda, 2018).

Functional Neurological symptom disorder (FND), which is also known as conversion disorder, is defined as a mental illness characterized by symptoms and signs impacting voluntary motor or sensory functions which cannot be explained by any neurological or medical condition. The Father of Psychoanalysis, Sigmund Freud, Suggested the term 'Conversion' stating that the development of certain symptoms is not explainable by bodily causes that reflect unconscious conflicts. The process of substitution of Somatic Symptoms for a repressed belief is called Conversion. He also believed that FND is a conversion disorder as he thought it has been a mental illness that is converted into a neurological disease. Conversion symptoms include paralysis, blindness, Psychogenic nonepileptic seizures, difficulty in walking, hallucinating, tingling sensations, numbness, loss of senses, chronic pain, headache/migraine (Ali et al., 2015).

The belief of hysteria to conversion are often traced back to 5th and 4th centuries before the Christian era (BCE), when the Father of Medicine, Hippocrates, elucidates hysteria as a condition in which a dehydrated womb wanders around the body looking for humidity. The uterus pressing on other organs, he said, would then develop the symptoms. Furthermore, in the 17th century, Rene Descartes posited mind-body dualism, in which the mind and body are two distinct entities that cannot coexist. This led to the establishment of a reductionist medical model with a dualistic perspective on symptom management. Whereas, in the 19th century, the emerging theories focused on the association of the central nervous system with hysterical symptoms. Psychodynamic theories also played a role because of Freud's description of symptom formation, in which converted bodily complaints are the result of unconscious conflict and effective motive. Thus, psychodynamic theory helped the study of hysteria and prepared the way for the concept of conversion symptoms. (Ali et al., 2015)

Individuals with Functional Neurological Symptom Disorder have a pathophysiological etiology in which their brain is unable to send and receive signals effectively. Interference in the lobe functioning and emotional processing is seen. Brain functions like memory, concentration, cognition and the processing of sensations can all be impaired. Psychogenic nonepileptic seizures and functional movement disorder are the two main types of Functional Neurological Symptom Disorder.

Diagnostic and Statistical Manual of Mental Disorders, fifth edition classifies Functional Neurological Symptom disorder (FNSD)/ Conversion disorder is categorized under the Somatic Symptom and related Disorders. According to the DSM-V, Functional neurological Symptom Disorder/Conversion Disorder is marked by having at least one symptom of altered voluntary motor or sensory function, no organic cause (neurological condition, substance use or physical disease) should be present which may explain the symptoms and lastly, symptoms are resulting in crucial distress in one's important areas of functioning such as social, occupational, personal (Boeckle, Liegl, Jank, et al., 2016).

Various research studies have revealed that panic, anxiety and depression disorders are the most commonly occurring co-morbidity disorder with conversion disorder (Khan, 2005). One of the research study results indicated that patients with conversion disorder presented symptoms of anxiety and depression as well. And patients who were diagnosed with Conversion Disorder, they were needed to be managed for symptoms of depression as well as anxiety for better end result (Kazan-Kizilkurt, MertAkgul, Izci, 2018). One of the studies revealed that a patient with Conversion disorder and Major depressive Disorder comorbidity benefited from pharmacotherapy and Psychodrama techniques and utilizing these two therapeutic approaches helped in the effectiveness of the treatment. It is seen that there is less emphasizes on a holistic formulation of treatment plan for managing symptoms of Conversion disorder as well as Major depressive Disorder. Therefore, the present study aims to understand implications of comorbidity of major depression disorder and conversion disorder: A case study with the elderly.

Methodology

Research design

Single case study design was used in this research

Sample

In current study, 65 y/o married female, came to visit the Psychiatric Out Patient Department (OPD). Patient A has studied till standard 7th and she belongs from a lower-middle class background. Patient is Hindu by religion and she resides in Mumbai, Maharashtra.

Materials

Case history and Mental status examination was administered on the patient. And DSM-V was used for diagnosing the patient.

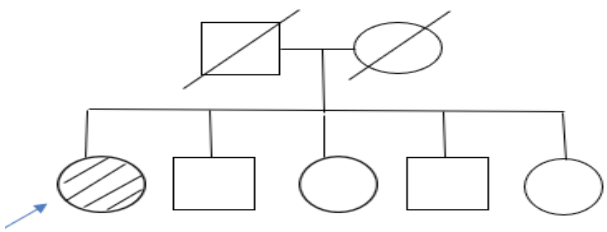
Procedure

Initially, rapport was established with patient A. Patient's data was collected by administering case history and mental status examination to make an accurate diagnosis. Patient A was debriefed about the present study's objective, potential risks and harms and right to withdraw. Informed consent was taken place. Also, she was notified that her detailed responses and data will be kept anonymous and confidential including patient's decision to withdraw from the study at any period of time.

Results

In the present study, a 65 y/o female came to visit the Psychiatric Out Patient Department (OPD) with depression symptoms. She had complaints of feelings of sadness, loss of interest in household work, insomnia, loss of appetite and recurrent thoughts of death along with the other physical complaints of tingling sensations in hand and head with constant headache. She also stated that her left body aches. She was experiencing these symptoms from the last 5-6months.

History of presenting illness



Patient informant states that she feels tensed about her sons and that they won't take care of her. Patient's sons left her and started living as a nuclear family in the year 2019. Also, she has a feeling that everyone will betray her and leave her alone. Patient A states that she is not able to sleep as she always worries about her children. And she doesn't like doing anything and is unable to feel pleasure in usual activities. Informant also confirms that she took 20 tablets of diabetes medication so that she can die.

Past medical or Psychiatric History

H/O hypotension and diabetes

N/H/O psychiatric illness

Family history

N/H/O any psychiatric illness in family

Personal History

Childhood- patient was a normal delivery child with no complications. All developmental milestones were achieved.

Occupational History- Patient studied till seventh standard and she is a homemaker

Psychosocial History- Patient is happily married and she is an outgoing person.

Sexual history: Menses Stopped 15 years ago

Mental Status Examination

Attitude and General Appearance: Patient is constantly falling down her head on the table. Patient is not cooperative. Patient seems irritable, seductive and apathetic

Mood: SAD, hopeless, depressed, anhedonia, fearful and suicidal

Affect: Anxious

Speech: Loud, High pitch, incoherent

Thought: Suicidal

Perception: intact

Orientation: Oriented to Place, Time and Person

Intelligence: Below average

Judgment: Intact

Insight: grade III (patient was aware about her being sick but she was blaming it on external factors)

Diagnostic approach

Patient A was experiencing symptoms of Conversion Disorder as well as Major depressive disorder. According to the DSM-V, patient A has the symptoms of Major Depressive Disorder (MDD) and Conversion disorder. She was experiencing feeling of sadness, difficulty in sleeping, loss of appetite, diminished interest or pleasure in her daily activity, and passive suicidal ideations. The symptoms have caused significant distress in her social functioning. Her symptoms aren't caused by a substance's physiological effects or by any other medical disorders. Also, she fulfilled the criteria for Conversion Disorder/Functional Neurological Symptom Disorder, as she was having somatic complaints which affected her sensory and motor functions. She was experiencing somatic complaints such as tingling sensations in her hands and head, left-side body ache and recurrent headache as it was seen that patient A was constantly falling her head on table during case study and MSE taking. Therefore, the patient was under the impression of Major Depressive Disorder and Conversion Disorder/Functional Neurological Symptom Disorder (FNSD).

Treatment approach

Considering, patient's provisional diagnosis comprised of two mental illness, a holistic treatment approach will help in managing patient's A complex symptoms and dysfunctions. Psychopharmacological approach for treatment can be used for patient A's condition. Whereas, there are various Non-psychopharmacological approaches that can be utilizes for the treatment of patient A.

Psychodynamic treatment: Hypnosis and free association therapy techniques can be used to understand repressed thoughts or emotions that resulted in the mental disorder. Patient A's unconscious unresolved conflicts which contributed to current condition of conversion symptoms (Left-side body ache, headache, tingling sensations) can be understood utilizing psychodynamic therapies.

Other Psychotherapies: Cognitive behavioral therapy helps in understanding, modifying and restructuring of irrational thoughts or beliefs. In the present case study, patient A feels that everyone is going to leave her and she will be alone, CBT can be helpful in identifying her cognitive distortions and maladaptive behaviors, and replacing these emotions, thoughts and behavior with rational thoughts and behavioral. Also, CBT is effective for major depressive disorder as well as conversion disorder. Family therapy, group therapy and dialectical behavioral therapy can also aid in effective management and treatment of mental disorders.

Complementary and Alternative treatments: Complementary and Alternative treatments emphasize on individual as a whole and various aspects altogether such as physical, emotional, social and spiritual. And these treatments are designed to support the natural innate healing functions of the human body. It includes Yoga, Mindfulness, Naturopathy, Ayurveda, Nutrition therapy, homeopathy, relaxation techniques, reiki, acupuncture and Expressive Art therapies etc.

Discussion

Patient was experiencing key symptoms of depression according to the diagnostic criteria. In the present study the patient was suffering from insomnia, lack of interest/pleasure, sadness, recurrent thoughts of death and loss of appetite. Patient was experiencing other symptoms like tingling sensations in hand and head, left-side body ache and recurrent headache. Patient's informant stated that she worries about her sons and now that they have left her and she has started leaving alone, the patient feels and fears betrayal. Patient feels that everyone will leave her and she will be left alone. Informant also claims that she ate 20 diabetes tablets at once so that she can die. Her informant also stated that she is not able to do her daily household work. Patient was experiencing a lack of energy and drive to care for herself and engaged in less physical activities.

In the Case history, the patient reported that there is no presence of any medical or psychological illness in her family. She has a history of Blood Pressure and diabetes. There is no history of OCD and mania/hypomania. Patient's menses stopped around 15-16 years ago.

Patient was constantly falling on her head on the table and she wasn't cooperative while conducting case history and MSE. On the Mental Status Examination, her general appearance and attitude was conscious, communicative, apathetic, seductive. As the patient has studied till standard 7th, her intelligence has been found below average. She had passive suicidal ideations. Patient's Judgment and perception is intact. Whereas, her level of insight is graded III. she had passive suicidal thoughts. She presented combined signs and symptoms of Conversion disorder/FNSD and Major depressive Disorder. Patient A, was given a provisional diagnosis of MDD and Conversion Disorder/ Functional Neurological Symptom Disorder as she met required diagnostic criteria's for both mental disorders. She was experiencing feeling of sadness, difficulty in sleeping, loss of appetite, diminished interest or pleasure in her daily activity, and passive suicidal ideations. And her symptoms have caused significant distress in her social functioning. Also, symptoms weren't produced or caused by any substance's physiological effects or by any other medical disorders. She had few somatic complaints such as tingling sensations in hand and head, left-side body ache and recurrent headache which indicated symptoms of Conversion Disorder/ Functional Neurological Symptom Disorder.

The formulation of treatment plan for patient A included psychopharmacological approach to manage her physiological dysfunctions. Though, her provisional diagnosis included two mental disorder that are Major depressive disorder and Conversion disorder. So, incorporation of Non-Psychopharmacological treatment along with Psychopharmacological treatment would help in managing her complex symptoms. Non-Psychopharmacological treatment involves Various Psychotherapies which emphasizes on identifying maladaptive behaviors, cognitive distortion's, irrational belief, interpersonal conflicts and coping patterns which are adversely contributing to the presenting illness such as Cognitive Behavioral therapy, Family therapy, Dialectical Behavioral Therapy, Psychodynamic therapy and Group therapy. One of the research studies revealed that family/marital/couple therapy and counselling, psychoeducation, exercising problem solving therapy, guided self-help, and behavioral activation treatments, acupuncture, computerized Cognitive behavioral therapy are the treatment elements are the treatments which has adequate level of evidence-based options for managing depression (Dirmaier, J., 2012). Also, there are

Complementary and Alternative interventions/therapies which can aid patient A in coping with the side effects of the medications, relieving her conversion symptoms of headache and left body ache, managing her stress and symptoms using various relaxation techniques (Biofeedback, Guided-Imagery, meditation), building a positive outlook towards life, regulating emotions in a better way, increasing general health and well-being.

Results of a research study indicated that yoga-based intervention can be one of the treatments utilized under Non-psychopharmacological approach in patients with Somatoform disorders (Sutar, R., Desai, G., Varambally, S., & Gangadhar, B. N., 2016). Yoga can be helpful in managing conversion symptoms of Tingling sensations in hands and head, headache and Left-body ache in the case of patient A. There are various Complementary and Alternative interventions comprises of Mindfulness, Yoga, Ayurveda, Acupuncture, Reiki, Naturopathy, Homeopathy and Expressive Art expressive. Holistic approach of treatments for patient A can aid in improving and promoting healthy behaviors alongside managing the physiological symptoms of existing disorders using psychopharmacological medicines.

Conclusion

This study emphasized on understanding implications of comorbidity of Major Depressive Disorder and Conversion Disorder/Functional Neurological Symptom Disorder in elderly. It is found that patient A was given a provisional diagnosis of Major Depressive Disorder and she needs to be managed for Conversion Disorder and Major Depressive Disorder symptoms appropriately utilizing psychopharmacological and Non-psychopharmacological treatment approach. Psychopharmacological approach will assist in managing the physiological symptoms of depression and Conversion Disorder/Functional Neurological Symptom Disorder. Whereas, Non-psychopharmacological approach will aid in cultivating Adaptive behavior, managing the side effects of the medicines, Positive attitude and coping styles, reducing pain both psychological and physiological, and overall psychological well-being of patient A.

15 Emotional Intelligence in People with Elderly

Sowmya B R* & Dr. Pooja Rai**

Abstract

Introduction : Emotional Intelligence is the competency of a person to understand, control, express, evaluate a person's own emotion and also that of the others in day to day interaction with the world around them. The development of emotions is a lifelong process which starts right from the time a baby is born till we grow old. However, it has been seen that there is an overall emotional decline in people with elderly. Thus, the objective of the present study will help understand whether the emotional quotient (EQ) or components of emotional intelligence (EI) of a person in his golden years declines or does it increase as they grow old.

Method: For this present study emotional intelligence development among the geriatric population is being reviewed using specific keywords. Out of 30 articles, 10 articles have been finalised to understand the impact of age on the development of EI.

Result: The articles for the review are studies that are based on the hypothesis that certain components of emotional intelligence increase as people age. Studies are consistent with this hypothesis and reveal the experiences people gain during their developmental stages and their interaction with other people. The paper will discuss different psychological assessments to measure emotional intelligence scales to assess the different components of emotional intelligence.

Conclusion: Emotional Intelligence and some of its components increase with age and help the elderly to deal with their and others emotions better when compared to what they were able to do during adulthood.

Keywords : Emotional Intelligence, Ageing

* Research Scholar, Department of Psychology, School of Sciences, Jain Deemed-to-be University, Bangalore

Introduction

Emotional Intelligence is the competency of a person to understand, control, express, evaluate a person's own emotion and that of the others in day to day interaction with the world around us. Wanye Payne was one of the first person who coined the term EI in his doctoral thesis. This term was later used by others like Keith Beasley, Beldoch and leuner. The term was popularised by Daniel Goleman with the publication of his book titled "emotional intelligence". Emotional intelligence is based on three models – the ability model which was proposed by John Mayer and Peter Salovey, mixed model by Daniel Goleman and the trait model was by K V Petrides. Emotional intelligence is studied by two types of tests – self-report tests and ability tests. The Mayer –Salovey – Caurso emotional intelligence test (MSCEIT) is an ability based test which includes the assessment of a person's skill. This assessment usually involves responding to a situation. The emotional and social competence inventory (ESCIII) is a self assessment scale where in the person himself or someone who knows the person rates the individual under different emotional situations.

Method

In this review paper and attempt is made to understand whether emotional quotient or the components of EI increase or decrease as the person grows old .Factors such as stress ,physical aliments ,illness and mental wellness are also affected by the development of EI.

Emotional Intelligencefrom development perspective

Research pertaining to the life span perspective and many other inquries have found a positive correlation between EI and age i.e. as people age their emotional quotient or competencies also increase (Salovey & Mayer 1990, Goleman 1998, Maddocks & Sparrows 1998). Emotional intelligence is made up of many components, the research work done on emotional intelligence in relation to older people addresses these components which have also been used as variables for study. One component is the psychosocial and physical factors in the elderly and its effect on emotional intelligence (Galdonna et al. 2018). The study emphasises that physical, psychological and social health are important factors that play an important part in the growth of EI.

Emotional intelligence components increase with age. while some elements of emotional intelligence are developed by giving training. One study showed that the emotional quotient in the elderly is more compared to people of other age groups, it is an ability that is developing and most likely the higher score on the assessment is due to the accumulation of the experiences that helps them to be better adjusted or more empathetic as they grow older (Fariselli et.al. 2008). In the work place also EI plays a major role in how a person interacts with the client and this is called as emotional labour strategy which refers to the rules of expressions of the organisation which can be very different than what that person is actually feeling. The outcome of the study indicated that there was a positive relationship between age and emotional labour strategy, which also in turn had a positive effect on their well-being. Older people showed more strategy when compared to people of other ages (Sliter et.al. 2013).

Education and Emotional Intelligence

A person's educational level is also another component that has shown a positive effect on the growth of emotional intelligence as people grow older. People who had a University education had more emotional quotient score compared to people who had only primary or secondary education. People who had studied upto the primary or the secondary level fared better on other elements of emotional intelligence using the Mayer – Salovey emotional intelligence scale (Cabello et.al. 2014). Emotional maturity, emotional competency and emotional sensitivity which are components of emotional intelligence, their growth was linked to ageing. Elderly people were seen to be more competent, sensitive and mature in their expression of emotions as compare to other age groups. In a study where the sample was clustered into three age groups and continuous statistics was taken for every respondent, the age group between 35 to 60 showed higher level of emotional intelligence compare to 17 to 23 year group and 24 to 34 year group (Sharma 2017).

Mental Health and Emotional Intelligence

Subjective well-being (SWB) which includes both satisfaction in life and emotional well-being, is one of the components that was measured in relation to ageing. The outcome of the study showed a positive relationship between age and subjective well-being (Chen et.al. 2016). Old age is also the age where we can see both physical and cognitive decline. Many research works support the fact that while there is decline in the cognitive and physical area, emotional ageing seems to improve as people grow older. Results of the present study indicates that if there is a shift in the way cognitive processing of emotional situations are done and motivation of emotional components are enhanced, this may curb the decline seen in cognitive development during old age. People with low EQ sores and also who lacked in social interaction skill, were found to have lower levels mental wellness (Tafti et al. 2018). Older people have many adjustment problems like inclusion of new family members. They also go through losses like losing of the spouse. EI was found to be helpful in using problem based method of coping, which results in increase of positive mood and better adjustment psychologically. The results in the study showed that promotion of EI activities can help improve the lifestyle of elderly persons.

Life satisfaction has a positive correlation with components of EI (Mostafaei et. al. 2019). Components of EI include relationship management, being aware of social situations, managing and being aware of others' emotions as well as self. There is also a positive correlation between psychological capital (resilience, hope, optimism, self efficiency) and life satisfaction.

Social support and important component among elderly people. Good social support helps people by giving them strength to plan and to lead their life successfully. A positive relationship between AI and support social support has identified that elderly people with IQ changing circumstances of life which also helps in maximising their well-being(Elsherif et al. 2021)

Emotional Intelligence as a coping mechanism

Old age is also a phase where the body becomes weak and people develop some common diseases and disorders. Some common diseases include blood pressure, diabetes, heart problems,

paralysis etc. Disorders like Parkinson, Alzheimer's and dementia cause more problems, which in some cases can lead to institutionalisation of old people as they cannot be taken care of at home. A comparative study where the EI, SWB and cognitive style of both institutionalised and non-institutionalised people where compared to understand whether there will be any significant differences among these factors (Bhattacharya et al. 2010). Ageing successfully is related to many factors and EI is one of the main factors. Stressful events of the past were used as a variable to understand whether it has an effect on successful ageing. But the results indicated a negative correlation between ageing and stressful past events, while emotional intelligence emerged as the main factor for ageing successfully (Guirado, 2021). Emotions have been used to solve problems in a much better way as people age. Their experiences lead to increase in emotional intelligence which helps in problem-solving and studies have shown that females are much more adept add using emotions for solving problems (Atkins, 2005).

Result

The studies reviewed for this paper all agree with the hypothesis that certain components of emotional intelligence increased with age. Some of the variables include psychosocial and physical factors, accumulation of experiences and developing emotional ability, emotional strategies, the education level of a person, emotional maturity and emotional sensitivity. Subjective well-being is one very important variable that is being studied in the recent years which is linked to life satisfaction also. High EQ scores of a person helps them to cope better with diseases and many stressful events be it past or the present. Emotional intelligence and its training during the developmental stages helps in curbing cognitive decline in elders and also helps them in better decision making and problem-solving.

Conclusion

Emotional intelligence in elders as compare to its development in the earlier years has helped the elderly in understanding, controlling, expressing, evaluating one's own emotion and emotion of others.

About the Editors

Dr. Pooja Varma is working currently as Head of department, Psychology and Assistant Professor of Psychology at Jain (Deemed-to-be) University. She specializes in Applied psychology (Gold Medallist) with work on Indigenous therapies, Expressive therapies, Health psychology, Developmental psychology, Clinical psychology and Counselling psychology. She has over a decade experience in teaching undergraduate and postgraduate courses in Psychology at a university level after completion of her Ph.D. in 2007. She has published more than twenty research papers in edited books, national and international journals. She has guided and taught PhD students as well as guided PG dissertations and PG diploma projects. She has conducted various workshops and guest lectures on various potent concerns and arenas of psychology. She is currently practising counselling psychologist working as a freelancer. She has organized various national and international conferences in the field. One of the successful event organized recently was an international conference on Healthy ageing with a key focus on geriatric health in collaboration with NIMHANS which was the sole reason for the conceptualization of this valuable book.

Dr. Alka Ranjan is an Assistant Professor of Psychology at Jain (Deemed-to-be) University. Her specialization is in Counselling Psychology and Public Health. She has 10 years of experience in teaching undergraduate and postgraduate courses in Psychology. She has more than 10 research papers in edited books, national and international journals. She is supervising PhD students and has guided undergraduate research projects and more than 100 master's dissertations. She has conducted various workshops, seminars and community outreach programs. She has organized 10 National and International Conferences. She is a practicing consultant psychologist and has qualified the exam for the licenced graduate professional counsellor in U.S.A. She has cross-cultural experience of working in the field of Counselling Psychology and Community Health in Singapore, U.S.A. and India.

Dr. Pooja Rai is an Assistant Professor of Psychology at Jain (Deemed-to-be) University. She specializes in Gerontology, cognitive disorders, memory, cognitive neuropsychology, neurodegenerative diseases, cognitive neurosciences, executive functions and neuropsychological assessment. She has immense experience in teaching undergraduate and postgraduate courses in subject like Clinical Psychology, Biological processes, Research Methods, Developmental psychology and so on. She has published more than 10 research papers in edited books, national and international journals in UGC, Scopus and web of sciences. She has guided and taught PhD students as well as guided PG dissertations. She has qualified UGC net and post doc fellowship in her field. She has conducted various workshops, seminars, conference, research based discussions and guest lectures on Neuropsychology and related fields.

PREFACE

Students in the social sciences, business, education, public health, and other relevant fields may find this book to be an excellent resource for learning about the steps involved in conducting scientific research. our lecture materials that we generated over the course of a decade of teaching the subject on Research Methods provide the foundation for this book. Students, young researchers, and professors who offer courses on research techniques make up the primary audience for this book. However, older researchers may also utilize this book as a useful and compact reference source.

The first and most crucial question that prospective readers of this book should have is, "How is it different from other text books that are now available on the market?" To be clear, there are two primary distinctions.

To begin, in contrast to other textbooks, this one is not just about "research techniques" (empirical data collecting and analysis), but also about the "research process" in its whole, from the very beginning to the very conclusion. The research technique is only one step in the whole research process, but perhaps the one that is least difficult and most regimented. The majority of textbooks provide an in-depth discussion of research methods, but they omit topics that are more difficult, less structured, and possibly more significant. These topics include theorizing and thinking like a researcher, both of which are frequently prerequisites for empirical research. In my experience, the majority of students are able to develop a reasonable level of research procedure competence, but they struggle to develop research topics that are engaging or relevant or to construct scientific ideas. In order to make up for this shortcoming, we have dedicated whole chapters to subjects like "Thinking Like a Researcher" and "Theories in Scientific Research," which are fundamental abilities for a young researcher.

Second, the book was written in a way that makes it concise and easy to carry. When we were writing the book, we made the decision to concentrate exclusively on the most important ideas and avoid

cluttering the pages with side topics or irrelevant information that would draw the attention of the readers away from the primary subject matter. The majority of classes consist of a substantial amount of assigned readings culled from the relevant academic field. Instead of burdening students with a lengthy text on top of their prescribed readings, this book is intended to supplement those readings by condensing all relevant themes in a single compact volume.

UNIT I

INTRODUCTION TO RESEARCH METHODOLOGY

Meaning of Research

The Department of Education and Training in Australia offers the following explanation of what constitutes research in their country:

Research can be defined as either the production of new information or the use of data that has already been gathered in an innovative and imaginative manner for the purpose of generating new ideas, ways of thinking, and comprehensions. Either way, the goal of research is to generate new ideas, ways of thinking, and comprehensions. In another sense, research may be seen as the act of using previously gleaned knowledge in a way that is novel and creative. One possible interpretation of the term "research" is as follows: This may include putting together a summary and doing an analysis of prior research to the point where it leads to discoveries that are novel and innovative.

This definition of research is consistent with a broad concept of research and experimental development (R&D), which is comprised of creative expression initiated on a comprehensive basis to increase the stock of knowledge, including knowledge of humanity, culture, and society, and the use of this knowledge base to devise new applications. Research and experimental development (R&D) is an abbreviation that stands for research and experimental development. R&D is an acronym that stands for "research and experimental development." Another way to say "R&D" is "research and experimental development." To put it another way, research is creative work done with the purpose of adding to the body of information already available, while research and development (R&D) is creative work done with the intention of contributing to the body of knowledge already available.

This concept of research incorporates all of the subfields of research, such as fundamental research, which may be carried out for

academic or strategic objectives, applied research, and experimental development. An example of applied research would be the collecting of new information via the process of doing original research with the particular intention of working toward the achievement of a definite and quantifiable goal (including a client-driven purpose).

When doing several searches, it is necessary to conduct more searches in order to locate anything. According to one definition of the word "research," the term "research" refers to human activity that includes the application of cognitive processes in the analysis of subject matter. This is the meaning of the word "research." The primary goals of applied research are to discover, understand, and build procedures and systems for the progression of human knowledge on a wide variety of scientific disciplines pertaining to our world and the universe. Applied research also aims to advance human understanding of a wide range of topics related to the scientific study of our universe. To be of benefit to society as a whole is one of the secondary purposes of applied research. Applied research aims to: The scientific method is often used while doing research; however, this is not always the case in every instance.

The term "scientific research" refers to a more general field of endeavour that encompasses both the "discipline" of study as well as the "art form" of study. The act of obtaining new information in a way that is well-structured and consistent is what is meant by the term "learning." The definition of "research" that can be found in the Merriam-Webster Dictionary describes it as "an lengthy examination or enquiry especially by hunt for unique information in any domain of competence." A Definition of What the Term "Research" Means in Its Own Right The process of carrying out research involves defining and redefining problems, developing hypotheses or suggesting potential solutions, collecting, organising, and analysing data, drawing inferences and coming to conclusions, and, as a final step, carefully evaluating the conclusions to determine whether or not they are consistent with the developing hypothesis.

Definitions of what it means for something to be considered research M. Stephenson and D. Slesinger, writing in the Encyclopedia of Social Sciences, defined research as "the manipulation of things,

concepts, or symbols for the purpose of generalising to extend, correct, or verify knowledge, whether that knowledge aids in the development of theory or in the practise of an art." This definition describes the purpose of research as "the manipulation of things, concepts, or symbols for the purpose of generalising to extend, correct, or verify knowledge." This definition explains the steps involved in doing research. Research may also be defined as "the manipulation of things, ideas, or symbols with the objective of generalising to extend, correct, or verify knowledge," which is another way of stating the same thing. 3

"The process of doing research is one that is distinguished by a high degree of organisation as well as an approach that is methodical," This term refers to the manner in which information is structured and presented as being systematic in the sense that there is a predefined sequence of activities and actions that you are expected to follow. When doing research, there are certain steps that must at all times be followed in order to attain the highest possible level of precision in the findings that can be obtained. If this is not done, the accuracy of the findings will suffer.

The research process is a rigorous approach that helps us find new facts and information, supports us in validating the existing knowledge, and motivates us to question things that are confusing and difficult to grasp based on the material that is already accessible. If you want to be a competent manager, you need to be able to recognise solutions to difficult situations and base your judgments on the information you get from those answers. Because of this, it is vital for you to have understanding of the many different processes that are involved in the process of obtaining solutions. You may get this information by reading books or watching documentaries.

Additionally, one is able to make sense of it by considering it in terms of the following:

• Research is an endeavour that is always being pursued, both in the vast majority of academic disciplines and professional sectors. This is the case both in the United States and internationally.

• It is important to keep this in mind while doing an in-depth analysis of how our organisation operates, how we implement rules, and how we instruct individuals in the many fields in which we work.

• It is the examination of processes in a methodical manner with the aim of discovering more effective methods to carry out operations, minimising the amount of work required to reach a goal, and determining whether or not the objectives are genuine.

• In point of fact, we are always engaged in the process of doing research, whether it be in the process of acquiring items for daily use, a vehicle, an electronic commodity, or the preparation for a vacation. It makes no difference what sort of purchase is being made; this is always the case.

According to Clifford Woody, the process of doing research consists of determining and reframing questions, formulating hypotheses, collecting, organising, and analysing data, and drawing conclusions. In this section of the chapter, it is highlighted that in order for any study to be effective in accomplishing the objectives that have been established, it must be carried out in a methodical and sensible manner.

The activity known as research is described as the process of obtaining new information with the intention of determining the solutions to a problem that has been posed. The two components of the word "research" are the words "re," which means "again," and "search," which means "find." Together, these words signify that we are engaging in an activity in order to look at an element once again or that we wish to seek out some new information about something. Together, these words signify that we are researching. [Case in point:] [Case in point:] [Case in point:] [Case in point:] The term may be understood to imply any one of these things. A Front Office Executive needs to educate themselves on the facilities, timings, and important characteristics of items and services that are available at the hotel in order to become an excellent sales professional in addition to being a host. For example, a person who wants to become an excellent sales professional in addition to being a host. These may be discovered in the many things and services that the hotel provides. " Curiosity is the seed

from which all creation springs; it is the place from which all else originates. It is better to have a reasonable level of healthy scepticism rather than an excessive quantity of self-assurance on occasion. Having an excessive amount of self-assurance might be dangerous. This is due to the fact that reasonable scepticism inevitably results in questioning, and questioning inevitably results in innovation "is a well-known proverb from Hudson that, when taken into consideration in the appropriate context, makes it simple to comprehend the significance of carrying out research. [Citation needed]

Different researchers, depending on the area in which they have chosen to concentrate their efforts and the resources that are available to them at any given point in time, have comprehended and described research in their respective fields in a manner that is unmistakably unique to themselves. This is the case regardless of the field. You will find that the background knowledge and major importance of each of these definitions are equal to one another, which is one of the things that you are going to discover. The only thing that really differentiates these definitions from one another is the technique that each author utilised when doing research inside their respective unique domains. This is the only factor that makes a difference.

The findings of the research that Thyer conducted back in 2001 may be summarised as follows: "The word "research" is broken down into its component parts, which are the syllables "re" and "search." These syllables, when put together, make up the phrase. The prefix "re" may have two distinct meanings: the first one is "once more," while the second one is "over and over again." The process of searching for something might imply to investigate something in depth and attentively, to test something out and see how it works, or to do more research on something. All of these are examples of what it means to "look for" something. They combine to form a phrase that, according to the definition found on dictionary.com, refers to "an attentive, methodical, and patient study and examination in any area of knowledge, carried out with the intention of establishing facts or principles.""

According to the edition of the Merriam-Webster Dictionary that is available online, the term "research" originates from the Middle

French word "recherche," which literally means "to go about searching." The first known written reference to the term dates back to 1577, when it was first documented.

Research is defined as "an structured investigation that makes use of trustworthy scientific procedure in order to solve difficulties and produce new information that is relevant across a range of situations," according to one definition of the term.

According to Martyn Shuttleworth, who offers a comprehensive definition of research when he says, "In the fullest meaning of the term, the definition of research covers the collecting of data, information, and facts for the progress of knowledge," the term "research" refers to the process of gathering information for the purpose of furthering one's understanding of a particular subject. A thorough comprehension of what it takes to do research has been shown here. According to Creswell's definition, research is "a series of approaches used to gather and evaluate information in order to expand our knowledge of a subject or situation." This definition of research is not the only one available; nonetheless, it is the definition that is most often used. The following are the three separate stages that may be split down into it: Following the formulation of a question as the first phase, the subsequent step is the collecting of pertinent data to address the issue in question, and finally, the question itself needs to be answered.

Research also contains the characteristics that are included in the following list:

a) The investigation has been given careful consideration, and it has been organised (a formal step-by-step procedure or sequence to carry out research activity is designed to assure the accuracy of data and the validity of processes). The categorization of the data, the act of making observations, and the interpretation of those findings are the three processes that are considered to be of the utmost significance in the scientific method. The amount of formality, rigour, verifiability, and general validity of the techniques used to get the conclusions that are attained through the use of scientific processes is what determines the findings that are obtained. The findings that are obtained can be used to draw conclusions about a variety of topics.

b) The challenges that it tackles are approached in an appropriate and respectable scientific manner (the technique used ought to be able to yield repeatable findings under situations that are comparable).

c) It should provide new information that may be used in a variety of various contexts and circumstances. (The results should be of the form that they are not unique to a particular problem or a set of circumstances; rather, they should be capable of being generalised for application to problems that are related.)

d) Due to the fact that it is a creative process, it helps to contribute to the development of a greater understanding of people, as well as social and cultural challenges and economic concerns.

e) Other individuals who seek to make use of the findings in the creation of new policies or applications of the findings of a research project for the benefit of the general public should find it advantageous.

The Aims and Objectives of the Research

If you describe the kinds of essential questions that are going to be taken into consideration during your investigation in your research objectives, you may be able to discover the overarching purpose or primary focus of your investigation. This may be possible because your research objectives will help direct your investigation. You are, in effect, telling me of the things that it is required for me to explore and analyse when you provide me with a description of the goals of your research. In spite of the fact that they are only different methods of referring to the same thing, the significance of the study may also be referred to as its objectives. It discusses a broad variety of topics, some of which are listed here for your convenience:

[Question: What are the objectives of the study, and why is it necessary to carry out research in the first place?] [Answer:]

1) To discover the truth in its purest form As we are all well aware, each and every type of research has its own objective, but the fundamental goal of the research is always to discover or obtain the information from the relevant marketplaces, societies, and the amount of people who participated in the study. A researcher will either conduct an analysis of the material that they uncover or seek for

information that is real or accurate in order to give answers to our inquiries that are relevant to the situation.

2) To accomplish new ideas: This aim of the study emphasises that anybody could come up with new ideas as a consequence of the research; hence, the objective is open to different interpretations. The process of discovering specific knowledge by making effective use of observation, optimization, and experimentation is referred to as research. Research refers to this kind of work that is carried out.

These are the scientific procedures that may be used in order to either identify the information or assess it, both of which are very essential in order to figure out how to proceed with the activity.

3) To evaluate the information: The initial purpose of the study is to locate the information, and then to evaluate it in a way that is suitable or effective so that they can easily construct the research issue and also solve it. This will allow them to easily construct the research issue and also solve it. This is done in order to facilitate the easy construction of the research issue as well as the solution to it.

A researcher will analyse the content by using a broad variety of scientific approaches and methods, statistical analyses and methods, as well as a significant number of tables and graphs.

4) To put a theory to the test in the methods that follow: During this phase of the investigation, the researcher will determine the correlational and causal linkages that exist between all of the different variables (it can also be said that the hypothesis testing research studies). In order to validate the hypothesis, the following is a summary of the total number of instances that were analysed as part of this research:

(a) as an integral component of the procedure for releasing an official statement,
(b) Figuring out the right significance level to use,
(c) Figuring out how to make distribution work for you in the most effective way possible,
(d) Choosing a random sample that is representative and establishing the lowest value for which there is an acceptable threshold,

(e) The analysis of the many potential events that could take place,
(f) doing an investigation of the disparities that exist among the different probabilities.

5) To design or carry out the study: As soon as all of the information has been gathered, the researcher will develop the framework of a research design that the organisation may employ. As a consequence of this, the organisation will have the capacity to quickly explain or recognise the framework of a certain area of research. When doing research, it is important to keep in mind that there are options available for both experimental and non-experimental designs. These are the two groups that may be used for the purpose of classifying the various research designs. As soon as the fundamental structure of the research project has been established, the researcher will start applying the findings to the issue at hand and will decide which of the available options is going to be the most useful in resolving the problems that have been uncovered.

6) To have a better understanding: This objective of the research seeks to have the researcher have a much better understanding of the topic at hand while also asking what else needs to be supported before the research can be considered purposeful, or what knowledge could be gathered from a more focused investigation, or scrutiny of the findings that have already been discovered. 7) To have a better understanding: This objective of the research seeks to have the researcher have a much better understanding of the topic at hand while also asking what else needs to be This objective of the study leads to the development of a more in-depth grasp of a particular issue on the part of the researcher.

The Importance of Motivation in the Scientific Process

Every inquiry starts with a collection of concepts, which are then researched further and drawn from a wide range of different scenarios and circumstances. In addition, the purpose of research is to approach an issue in an orderly way with the idea of discovering viable solutions to that problem. Research is a procedure that entails developing an in-depth study as well as completing investigations of crucial areas in order to discover a solution to an issue. The goal of this process is to

find a way to solve the problem. This is done in the interest of locating responses to various inquiries. In general, research is a procedure that involves an approach that is methodical. Its purpose is to ensure that the information acquired is reasonable and that it is supported by qualitative information. Accuracy in the information obtained is intended to be the result of this endeavor's primary focus. The establishment of a research technique, the collection and description of data, and the procedure of reporting information to the proper parties are all included in this step of the process. Research has the potential to provide solutions that will solve problems that have been brought about as a consequence of a problem in this way, and it can do so in a way that will clarify things up.

One of the most essential occupations in the modern academic world is teaching, but other key responsibilities include doing research and publishing the findings of that study. Teaching is not the only important academic job. These three commitments are in some way or another inexorably tied to one another. Research not only provides new information but also contributes to the body of previously held knowledge while simultaneously adding to the expansion of previously held knowledge. In other words, research not only produces new information but also adds to the body of previously held knowledge. Research is not just something that must be done in order to get a degree, but it has also become something of a responsibility that must be fulfilled. When a higher education establishment demonstrates outstanding performance in the areas of research and the production of publications that are of a high grade, the status of such an establishment may be elevated. This is a fact that cannot be disputed, and it is a fact that can elevate the status of such an institution. The researcher is responsible for determining which technique of publishing is most appropriate for each and every result that is acquired and must do so for all of the results.

You should not only be a good researcher, but you should also be an amazing instructor.

Every exceptional student has their very own one-of-a-kind strategy that they follow in order to be able to carry out the

responsibilities of their profession effectively. The work that has to be done by an academic is often difficult and has to be finished by a specified date in order to be considered satisfactory. It is possible that beginners may find this goal to be challenging since the activities may seem to have no link to one another. As a consequence of this apparent lack of connection, it is possible that beginners will struggle to meet this expectation. Even if a novice is capable of completing all of the tasks that have been assigned to them, the quality of the work that they produce may not be very impressive. The purpose of all of the interviews that were carried out for the purpose of this work was to collect information from productive researchers and academics about the methods that they use to organise their careers as lecturers and researchers. This information was gathered from the interviews that were carried out. These interviews, which were carried out, were the source of the information that was acquired. In order to make things easier for you, the following paragraphs provide a condensed and simplified version of a summary of the ideas and recommendations provided by those individuals who served as role models.

The driving force behind this research:

• Take responsibility for your time management, and organise your work in a way that makes sense to you. Creating a logical plan, for instance, may make life easier to manage in terms of issues such as time management. This is one benefit of developing a logical strategy. It is possible to accomplish this objective by the use of several pieces of software, for instance Google Calendar.

• It is crucial for researchers to bear in mind that the fundamental reason for the development of their study is not money but rather a deep interest in the topic on which they are working. This is because money is not the primary motivation for developing their study. This is a very important fact to bear in mind, since it is the fundamental reason why they decided to carry out their research in the first place.

• Every researcher needs to have a high degree of self-assurance and should never give up easily, even if there comes a point in their investigation when it seems as if they have reached a dead end in their search for answers. If they keep looking, they will eventually find what

they are looking for. If, on the other hand, the researcher is really interested in expanding their own body of knowledge, then the research project will, in the end, be an endeavour that is successful.

• Researchers should never keep quiet about newly obtained information and should always be happy to share information with their colleagues | Researchers should always be eager to share knowledge with their colleagues • Researchers should never keep quiet about newly found information When working on a group project, cooperation is not only one of the most valuable assets that can be brought to the table, but it is also one of the most vital things that can be done.

• It is absolutely necessary to make sacrifices of both one's time and one's energy since there is no easy way to produce remarkable study discoveries. This is because there is no shortcut.

The Inspiration Behind the Writing

• Acquiring the abilities necessary to produce writing of an exceptional and high-quality level can only be accomplished via the accumulation of experience, and this is true for both reading and writing. Reading and writing both need experience. Learning should be something that is done on a continual basis and should be something that is done on a daily basis.

• Before beginning to write, we need to give careful thought to the purpose of the writing, since the purpose of the writing defines the scope of each individual writing project. This is why we need to pay careful consideration to the purpose of the writing. • After we have identified why we are writing this, we can then go on to the first step of the process, which is getting started. • The degree to which the author is willing to dedicate oneself entirely to the act of writing is one of the most significant elements that will define the quality of the final product. This is one of the most important aspects that will determine the quality of the finished output. A piece of work that is of a high quality will be beneficial not just to the scientific community, but also to the community as a whole in its whole. This is because the scientific community is merely one subset of the larger community.

• The reader needs to have a comprehensive understanding of what should be written, and the writer needs to have a comprehensive understanding of what should be written. In order to have a higher level of desire to finish the writing, the writer should choose tasks that have shorter deadlines, such as paper works and modules.

Beginning writers may benefit from working on a paper for a conference since it may help them enhance their general writing abilities. Working on a paper for a conference may be useful. With the help of this expertise, you will be able to develop a solid basis for your writing.

• A well-respected mentor has the ability to be an effective reviewer of the work that is produced by their mentees. This is because of the high level of credibility that the mentor has.

• In order to ensure that the clients or customers are pleased with the work that has been done, it is essential that the prescribed writing format for the project be adhered to in an exacting manner at all times. This will guarantee that there are no hiccups in the execution of the project.

• If you want to be a competent writer, you need to have a firm command of the language and the ability to interpret research data in a way that will have a huge influence on the people who are reading your work in a manner that will have a major impact on the people who are reading your work.

Plagiarism is a serious crime, thus it is imperative that authors never lift the concepts or words of others and use them in their own writing without giving proper credit. It is essential for writers to never steal the concepts or phrases of others in their work. Authors have an extra obligation to ensure that their works are fully original by implementing the appropriate safety measures. They have a duty to bring to the attention of the audience any instances in which they have taken ideas from the works of other authors and explain how they have done so.

The Value of Inspiring Others in a Learning Environment

• If you want to be a successful educator, the first and most crucial thing you need to do is develop a love for the work that you do.

This is the single most significant thing you can do to improve your teaching abilities. Work that is performed with passion will inspire the individual performing it to put up their best effort while they are working on the task at hand. It is possible to nurture interest, even if there is a lack of it, by becoming more cognizant of the responsibilities that come with being a professor. • When it comes to becoming a successful teacher, one of the most crucial talents to acquire is the ability to manage one's time efficiently. This is one of the most vital abilities to develop. Because time spent in the office is frequently devoted to other pursuits, such as meetings and lectures, lecturers should make more room in their schedules for writing in order to get the most out of the time they spend in the workplace. This will allow them to maximise the value of the time they spend there. To keep their level of competence in their respective professions at a high level and to continue to develop it, educators need to make research a mandatory part of their professional lives. This is done with the expectation that the findings of the research will result in innovations in the field of study, which will ultimately be to the advantage of the nation.

Tips to Become A Successful Academic

Teaching, doing research, publishing academic work, offering academic advice and services, and giving services to students are the five fundamental academic activities that educators and researchers are obligated to take part in. Participating in all of these different kinds of activities will be challenging, especially at the beginning of the process. However, as time goes on, there will be a significant reduction in the difficulty of effectively carrying this out.

• In order for lecturers to cultivate their competence in their respective professions, they should place a high priority on their fundamental responsibilities, which include instructing students, doing research, and writing. They will be able to better serve their pupils as a result of this. It is critical to do empirical study on novel ideas that have not been investigated to an adequate level up to this point in time. It's conceivable that ideas that have been used in the past or that are recycled might have their worth diminished as a result. Never give in to your hesitance or wait for the backing of others before starting a new

enterprise. Both of these things will only hold you back. You won't go very far with either one.

• In order for researchers to successfully complete their study, they need to be prompt and active because, if the time span is too long, other researchers who are working on similar projects will publish their findings before the researchers who are doing the original research. If the time span is too long, the researchers who are doing the original research will not be able to successfully complete their study. This is due to the fact that other academics who are working on similar topics will publish their results before the researchers who are undertaking the original study publish theirs. On the other hand, one cannot only presume that the degree of research that was carried out met the necessary criteria and proceed from there.

• Because we do not want other people to find any rationale to throw doubt on the validity of our results, the principles of research ethics need to be adhered to stringently throughout the whole of the project. This is because we do not want to compromise the integrity of the study. Because of this, it is very necessary that the guidelines for ethical conduct in research be followed.

Why should someone go through the trouble of doing research?

To provide insight into prospective courses of action, to compile evidence in support of hypotheses, and to make a substantial contribution to the expansion of knowledge in a particular area of study are the fundamental goals of research. This article demonstrates the value of research, as well as the different reasons why it is vital for all people—not just students and scientists—to engage in it. In addition to this, the essay emphasises the multiple reasons why research is necessary for everyone. To provide a more precise explanation, the main emphasis of the article is on the significance of doing research.

In spite of the fact that it would seem to be self-evident that research is essential, a substantial percentage of individuals continue to steer clear of it like the plague. On the other hand, doing research is not simply useful for individuals who aspire to study in any subject, regardless of whether or not they are members of a research institution;

rather, it is an absolute must for such individuals to carry out such research.

Why does it make a difference to do research, and why is it so important for our day-to-day lives?

- It is a tool that makes the process of education more manageable while also extending one's intellectual frontiers and increasing one's intellectual horizons.
- It is a tool that assists individuals in better comprehending challenges, while at the same time elevating general public knowledge of issues of this kind.
- The success of our company may, in part, be attributed to this component, which contributes to our overall success.
- It affords us the opportunity to debunk urban legends and strengthen our cases for why the reality is more compelling.
- It is a tool for locating possibilities, evaluating the worth of those chances, and seizing those opportunities when they become available.
- It encourages a love of reading, as well as self-confidence in writing, reading, and comprehending material, as well as the capacity to convey this knowledge with other people.
- As a direct result of this, the mental capabilities are both nourished and exercised, which is beneficial.

Research is essential for all kinds of people, whether they are students, academics, professionals, or those who are not in those professions. However, those in the academic world and students aren't the only ones that need it. It is a tool that may facilitate easier learning and help one's existing knowledge become more comprehensive. It is essential for aspiring authors as well as established writers, and it does not matter if they write offline or online; either way, it applies to both groups. It is necessary for all of them, regardless of whether or not they decide to publish their work.

By engaging in research, persons who are not experts but who place a high value on education have the chance to gain information about the world as well as skills that will aid them in surviving and improving their life in ways that will be beneficial to them. On the

other hand, in order to find an interesting subject to talk or write about, professionals and writers need to look for sources of inspiration other than their own personal experiences. This is necessary in order to discover an interesting topic to speak or write about. One of the many reasons research may be done is to find out what the general public would be interested in learning or what academics want people to understand or think about. This is only one of the many reasons research might be done. This is only one of the many different reasons why research might be carried out. As a consequence of this, doing research is a necessary step in the process of acquiring new knowledge, and the same is true when it comes to the accumulation of new information.

It is common parlance to characterise one's knowledge as a truthful assertion that is kept inside one's own head. It is a reference to the facts that are processed by the human brain and are derived through either objective insights or the results of investigations. A simple definition of it would be anything that makes reference to facts. It is possible to acquire it through a variety of different means, such as through the reading of books and articles, the observation of experts in person or on television, the observation of investigative or documentary television shows, the participation in social activities, and the performance of scientific experiments. All of these methods can be utilised to acquire it. One technique to check the validity and correctness of the information collected via research is to cross-reference one set of research results with another set of sources. This is an example of a cross-reference.

Numerous Articles and Research Studies Covering a Wide Range of Topics Concerning the Necessity of Conducting Research

David Truncellito, an associate professor of philosophy at Yale University, outlines his findings in a paper titled "Epistemology," in which he distinguishes between three separate types of knowledge (n.d.). There are three main types of knowledge, which are as follows: procedural (also known as competence or know-how), acquaintance (also known as familiarity), and propositional knowledge (description of "a fact or a state of affairs").

Brain Research UK, a medical research charity that is situated in the United Kingdom and was previously known as the Brain Research Trust, recognises the importance of research in the process of gathering new information. Brain Research UK was originally known as the Brain Research Trust. Before changing its name, Brain Research UK was known as the Brain Research Trust. Research is considered to be of utmost significance in terms of the importance of identifying effective remedies for illnesses as well as approaches that may be employed to prevent individuals from acquiring diseases in the first place. As a consequence of this, it is vital to do study in order to determine whether or not previous studies support one's beliefs and whether or not these concepts still need more evidence in order to be called knowledge.

In 2016, a group of researchers interested in the field of psychology joined together to carry out an investigation with the purpose of discovering whether or not there is a correlation between obtaining adequate sleep and being able to retrieve memories that have been stored in the past. In "The researchers came to the conclusion that "interleaving sleep between learning sessions not only cut the amount of practise needed by half but also secured much improved long-term recall." This research was presented in a publication with the title "Relearn Faster and Retain Longer: Along with Practice, Sleep Makes Perfect." This finding was stated in the study article that was published under the title "Relearn Faster and Retain Longer: Along with Practice, Sleep Makes Perfect." It is a well-known fact that getting some shut-eye after a learning session is beneficial; however, research has shown that sleeping during the time frame in which one learning session is followed by another is much more effective." This research lends credence to the theory that people are better able to retain knowledge for longer periods of time after engaging in activities that include both repetition and sleep. Specifically, the research demonstrates that people are better able to retain knowledge for longer periods of time after sleeping on it. In particular, the study shows that individuals are able to remember information for longer stretches of time once they have had time to reflect on it while they were sleeping. Their results also highlight how critically crucial sleep is to the proper functioning of a

healthy brain, which is another significant takeaway from their research.

1) A Way to Gain a Deeper Understanding of the Issues at Hand and Raise Awareness Among the General Public

Employing Research as a Tool to Acquire a Greater Comprehension of Existing Problems in Order to Better Prepare for Future Challenges

In both fictional and nonfictional episodes and films that are shown on television and in movie theatres, the use of research is a regular practise that is often seen. Oprah Winfrey, for example, would not have been able to achieve the incredible success that she has as a news anchor and presenter of a television programme if she had chosen not to do study on certain topics and famous persons. If she had done so, she would have had a much harder time breaking into the industry. She would have had a lot harder difficulty breaking into the business if she had done that. It would have made her job much more difficult.

2) Implementing Research in Order to Acquire a Deeper Understanding of People

Actors who work in the film and television industries frequently conduct interviews with real people in order to gain a more profound comprehension of the characters that they play on screen. This makes it easier for the actors to empathise with the characters they play. In order to receive an insider's perspective on what it's like to have a given character, actors have, among other things, collaborated with detectives, boxers, chemists, company owners, criminals, and instructors. This has allowed them to get this knowledge. Because of this, the performers are able to more convincingly convey the events that their characters go through. Some people will go so far as to put themselves in the position of their characters in order to have a deeper understanding of the difficulties those characters face. This could involve spending time in jail or a drug rehabilitation centre, beginning a strenuous diet or exercise routine, learning how to sail a sailboat, gaining a considerable amount of weight, or losing a significant amount of weight. Other options include learning a new skill, such as

how to drive a stick shift or learning a musical instrument. In addition to that, it can mean putting on a significant amount of weight. Many people read works of fiction, biographies, or diaries in order to get a better perspective or grasp of the tale that they have been entrusted to tell. This might be because they want to learn more about the subject matter or because they are interested in the topic. This might be due to causes in your personal life or reasons in your work life.

3) Using Research as Part of the Creative Writing Process in Order to Generate More Realistic Stories

There are a lot of movies, plays that are performed in theatres, television dramas, and videos that are put on the internet that portray narratives that are based on real-life occurrences and situations. Some examples of these types of media include: It is possible to find examples of these. When it comes to entertaining and enlightening audiences across a variety of media channels, a professional writer or content producer understands how important research is in substantiating the background of the story they are delivering. This understanding is based on the fact that they are aware of the importance of research. To put it another way, they are aware of the importance of the research that they carry out.

According to the concepts that Terry Freedman presented in "The Importance of Research for ICT Teachers" (2011), "Research may shine light on difficulties we didn't even know existed, and can raise concerns we hadn't even realised even required asking" (Research may shine light on difficulties we didn't even know existed, and can raise concerns we hadn't even realised even required asking) (The results of research may throw light on challenges that we were unaware ever existed, and it may also pose questions that we were unaware even needed to be asked.) Because of this, the vast majority of authors of both fictional and factual reports do research, since doing so enables them to develop intriguing stories and ensures that their credibility is maintained. This holds true for writers of both fictional and nonfictional works of storytelling.

4) The Contribution That Your Support Will Make Towards Our Achieving Financial Success

The Rewards That May Be Obtained If One Is Willing To Put In The Effort And Time Required For Research And Development (R&D)

It is possible that doing research will be beneficial to the corporate world. Research and development, which is often referred to as R & D at times, is a field that is an area of investment for many prosperous firms, particularly those who operate in the consumer goods or mass market item manufacturing industries. Research and development is another name for this particular subject area. In a variety of different sectors, including agriculture, the food and beverage industry, manufacturing, healthcare and pharmaceuticals, computer software, aerospace, aviation, and the energy business, the costs involved with research and development are rather high. This is because the scientific and engineering methods that are used in these sectors play a significant role in the production and advancement of the goods and services offered by these businesses.

5) Carrying Out Research Concerning the Market and Specifying Particular Marketing Goals

A firm may benefit from research in a number of other ways as well, including the maintenance of a favourable commercial image, the retention of current customers, and the acquisition of new customers via the use of targeted marketing. Research is the key to achieving all of these objectives, and it should be your first priority. The use of research in real-world settings has the potential to provide the benefits outlined above. Because marketing is a kind of communication, for it to be successful, companies need to have a large amount of information about the people who buy the products and services they provide.

This is typically accomplished through the utilisation of market research, which may involve, among other things, the review of psychological studies concerning consumption, the facilitation of focus groups, the beta testing of products with a specific subset of customers, the distribution of satisfaction surveys to existing customers, and the investigation of the primary competitors of the company. In general, this objective is reached through the utilisation of market research. In

most cases, this purpose may be accomplished by doing research on consumer preferences and preferences currently held by the market. The most successful companies, regardless of their size, are those who construct their product designs, service offerings, and marketing messages on the basis of the insights obtained by doing in-depth research. This holds true for both big and small firms. This is true irrespective of the size of the organisation.

6) Leveraging the Applications of Research to Make the Most of Your Current Position and Future Career Opportunities

It is essential for people who are seeking for work or who are interested in developing their careers to do research if they want to increase their chances of success. People may improve their chances of obtaining work by doing in-depth study, searching for open opportunities through job-posting websites, and getting in contact with recruitment organisations. These three actions can all be done online. This may make it easier for individuals to find jobs. Research offers a number of benefits, one of which is the potential to assist individuals in determining whether or not employment opportunities actually exist for them. A job seeker or travelling worker who is naive yet optimistic, but who does not conduct their homework, runs the risk of being taken advantage of by unethical headhunters, phoney employment offers, or even outright frauds. This is especially true if the person does not complete their investigation.

Job seekers have the ability to learn about the experiences that others have had with an employer that they are thinking about working for or a placement agency that they are thinking about employing thanks to websites such as Glassdoor and organisations such as the Better Business Bureau. Job seekers have the ability to learn about the experiences that others have had with an employer that they are thinking about working for or a placement agency that they are thinking about employing. Job seekers have the ability to learn about the experiences that others have had with an employer that they are considering working for or a placement agency that they are considering utilising when they read reviews on the Internet (BBB). Once they have identified an academic course or training for skills

development that is available for free or for a nominal fee, students and professionals are able to conduct additional research to determine whether or not they are qualified for particular roles, as well as to learn the requirements and application deadlines for those roles. This is possible once they have discovered an academic course or training for skills development that is offered for skills development. After they have identified a training programme or academic course that is available for skill development, the next step that can be taken is the one that is being discussed here.

7) Using Research to Its Full Potential in Order to Realize the Highest Possible Returns on Investment

In addition, members of civil society could gain advantages as a result of research in a variety of different ways. The acquisition of financial resources for the many initiatives and research endeavours that those who are interested in finding solutions to societal issues have planned should be a high priority for those who are serious about their pursuit of such solutions. However, not all funding organisations are accepting proposals throughout the entire year, and they are not all interested in discovering solutions to the same kinds of societal issues. As a consequence of this, it is of the utmost importance to conduct research in order to identify organisations whose goals are compatible with the goals of particular advocacy campaigns or initiatives to bring about social change.

8) Research That Backs Up the Theory and Method of Reflective Thinking

Reading and writing are two processes that are crucial components of the research process that you are required to finish. It is possible for an individual to maintain both their comprehension and their capacity for critical thinking with the assistance of these two literacy processes. The process of doing research is going to be a lot more challenging for you if you don't have these talents. Reading gives one access to a large store of knowledge, while writing teaches us how to express our thoughts and translate abstract ideas into concepts that others can comprehend. Reading gives one access to a great store of

information. Reading also offers one the opportunity to have access to a vast store of information. Reading broadens a person's perspective on the world and deepens their understanding of the world in which they live.

Reading and writing are necessary skills for doing research, but it is also necessary to be able to listen to people and communicate oneself verbally. It is difficult to conduct research without having all of these skills. We have the opportunity to collect information and develop study topics when we take part in activities such as conducting interviews, going to events where new information is created, and taking part in casual discussion. Reading and writing, in addition to all of these other activities, have an influence on our capacity for critical thinking that is analogous to that of the other activities. Hearing professionals talk about the job that they do might potentially help us look at problems from fresh angles and add new approaches to our toolset for acquiring information.

9) The dissemination of discoveries in order to promote a deeper level of comprehension among a wider population

Researchers, regardless of whether they are affiliated with academic institutions or not, now have the opportunity to disseminate their findings to a more extensive readership as a result of the internet's capacity to facilitate the proliferation of information and the interconnectivity of people and locations. This is because the internet has the ability to facilitate the proliferation of information and the interconnectivity of people and locations. This activity is considered by some as a method of bolstering one's ego, while others see it as a means of piqueing one's curiosity and motivating greater investigation into certain subjects or situations. Both of these interpretations are valid, depending on who is doing the viewing.

Research not only assists in the development of these fundamental life skills but also makes learning an endeavour that continues throughout one's whole life. Literacy helps increase a person's social and economic mobility as well as their level of awareness, and research contributes to the improvement of these core life skills.

10) Gives It the Emotional and Mental Stimulation, as Well as the Nutritional Support, That It Needs in Order to Thrive

Analyses of Reasoning and a Concentration on Both Physical and Mental Health

It is true that curiosity may be fatal, but it also serves to keep the intellect fresh and keeps one motivated to find answers to questions. "helps students gain critical thinking talents... valuable for any field of higher education," as stated in an article written by Todd Johnson and published by College Admission Partners (n.d.), the author outlines the various ways in which scientific research, in particular, "helps students gain critical thinking talents." The creative and logical qualities that are already there in each of us may be maintained via the stimulation of the brain through activities such as learning new things and taking part in critical thinking. It has been hypothesised that maintaining a busy mind might aid in the avoidance of some mental diseases, including Alzheimer's disease.

These Qualities are Commonly Observed in Scientific Investigations

The characteristics of a piece of research provide light on any underlying biases, assumptions, or subjective inaccuracies that may or may not be present in the study. [Case in point:] [Case in point:] [Case in point:] [Cas [Here's a good example:] The phrases are used rather often in research, and the achievement of a satisfactory conclusion to any study is dependant on the amount of accuracy shown by the terms. To summarise them, consider the following:

- Generalized
- Controlled
- Exhaustive
- Empirical
- Being Organized
- Reliability
- The ability to evaluate and verify the outcomes of the analysis.
- Considers the existence of the hypothesis.
- Skilled in deductive reasoning and precise expression

• A sense of veracity
• Critical

1) In general, the researcher would normally divide the population that has been identified into smaller samples. The particulars of this procedure will depend on the resources that are available at the time that the study is being carried out. Given that it is commonly accepted that this specific sample is an accurate representative of the target population, the conclusions that are formed from it should be applicable to and indicative of the target population as a whole. The diagnostic information that is gathered from the study of these samples needs to produce a credible estimate of the percentage of the entire population that adheres to a particular ideology, views, stigmatisation, driving force, etc. This estimate needs to be derived from the information that is collected during the diagnostic process. This estimate has to be produced from the data that has been examined, which has been acquired via study. For instance, if a researcher wanted to understand the occupancy statistics and patterns of small hotels and resorts in a particular city, they would first have to divide the city into zones, and then they would investigate selected properties. This would be necessary in order for the researcher to gain the necessary information (East, West, North, South and Central). For the sake of classification and selection for the study, it's probable that he would also classify the residences into groups according to the quantity of rooms that are in each one. This will ensure that the findings are true representations of the whole city.

2) Controlled: The concept of control suggests that, in order to investigate the possibility of a causal link existing between two variables (factors), you should design the experiment in such a manner as to reduce the influence of any other factors that may be relevant to the investigation. This is because the idea of control suggests that in order to investigate the possibility of a causal link existing between two variables (factors), you should design the experiment in such a manner as to investigate the There are some variables that are taken into consideration to be controlling factors, and there are also other

variables that may be taken into consideration to be the likely repercussions of controlling factors.

Experiments that take place in a controlled environment, like a laboratory, such as those in the pure sciences like chemistry, can be managed; however, no study that tackles social issues can be managed. Studies of locations, for instance, are unable to be controlled because they take into account aspects such as location, climate, accessibility, seasonality, and other such aspects. On the other hand, research into the impact of standard operating procedures in a hotel applied to a particular service can be controlled.

3) Comprehensive: Using utmost care is required in order to ensure that the approaches used to discover answers to questions are appropriate, germane, and reasonable. This may be accomplished by being thorough. Once again, the degree of rigour varies greatly between the physical sciences and the social sciences, as well as across the several subfields that fall under the umbrella of the social sciences.

4) The empirical method requires that the techniques that are used be evaluated to ensure that they are accurate, and the progression from one step to the next must be logically consistent. This indicates that any conclusions drawn are based upon solid evidence gained from information that was gathered through experiences or observations that were carried out in real life. Specifically, this indicates that the information was gathered through experiences or observations that were carried out in real life.

When it is indicated that a piece of study contains an empirical component, this indicates that it was carried out in line with rigorous scientific procedures and processes. It is much simpler to demonstrate that a piece of study is legitimate from a scientific perspective if it is quantitative rather than qualitative. When doing qualitative research, it is quite simple to let one's own prejudices and biases get in the way.

5) Methodical: The plan or procedure that is being developed in order to carry out an inquiry has to be thoroughly planned in order to ensure that the utilization of the available resources is maximized. The expected outcomes will never be achieved by following procedures that are either random or poorly designed. In order to achieve the desired outcome, it is necessary to carry out the acts in the sequence that makes

the most logical sense. As an example, the meal cannot begin with dessert being served first at a restaurant that is appropriate for a five-star hotel. Instead, it has to start with either the appetizer or the soup course, whichever comes first.

6) Reliability: The degree to which one may depend on the results of a measurement, calculation, or specification to be accurate is referred to as the reliability of the results. One may describe this in terms of a percentage.

Despite the fact that it might be difficult to measure anything accurately, there is presently machinery that can assess the reliability of a research.

The results of several iterations of an experiment, test, measurement method, study, research equipment, instrument, or methodology need to be consistent with one another. The degree to which this is true is what is meant when we talk about repeatability. The reliability of a piece of research is measured by its ability to be replicated with the same group of participants, using the same procedures, and yet arriving at the same conclusions each time.

7) Validity and Verifiability: Validity is the degree to which an idea, conclusion, or measurement is well-founded and likely corresponds correctly to the real world. Verifiability is the degree to which an idea, conclusion, or measurement can be independently verified. The verifiability of an idea, conclusion, or measurement refers to the extent to which it is possible to test the concept, conclusion, or measurement. It is possible to trace the etymology of the word "valid" back to the Latin word validus, which may be translated as "strong." In no way can this be construed as implying that something is completely guaranteed or that there are conditions that cannot be avoided. The degree to which a measuring instrument (such as a test used in education, for example) really measures the item that it claims to measure is considered to be an indication of the tool's validity. The viability of an argument may be evaluated based on the significance that should be attached to different types of evidence. In the context of academic inquiry, the word "validity" relates to the extent to which it is possible for us to ascertain whether certain study findings, statements, or assumptions are true or false. The phrase "validation" refers to the

correctness of a measurement, regardless of whether or not it measures what it is intended to measure. Validation measures the accuracy of a measurement. In addition to this, it investigates the ways in which research might be used to the process of seeking answers to questions raised by a number of different scenarios. This gives a clear and focused direction for the work that is being put into the study. The findings of a study should be able to be independently confirmed, not only by the investigator who was responsible for carrying out the investigation, but also by any other individual who is interested in carrying out a similar investigation using the same procedures and in conditions that are comparable to those that were utilized in the initial investigation.

8) Incorporates a Hypothesis: The creation of a hypothesis ought to always act as the first phase of any research endeavour. On the basis of the little evidence that is currently available, a hypothesis or an explanation is formed as a starting point for future research. This hypothesis or explanation is a guess or a recommended explanation. An educated prediction regarding the relationship between two or more variables is an example of what is meant by the meaning of the term "hypothesis." This definition accurately conveys the core meaning of the term "hypothesis." To put this another way, a hypothesis is a theory or idea on which one starts to build their work before the idea is really put into practice via research. It is a question that serves as the basis, which is then referred to as the hypothesis; this hypothesis may or may not draw a logical conclusion. The question that serves as the foundation is called the hypothesis. When the research is done, the hypothesis can be proved to be wrong, flawed, or unjustified since it was not established on any evidence.

One possible definition for the term "hypothesis" is "an educated and well-informed guess or explanation for a particular issue." As part of the research process, the hypothesis needs to be put to the test. After that, the results of the tests have to be analyzed in connection to the hypothesis and the reality in which you find yourself. When a researcher formulates a hypothesis, they are, in effect, drawing out a road map for themselves to follow over the course of the research endeavour. It provides the researcher with information regarding the

factors that are significant to investigate, as well as how those factors may be related to one another or how they may be caused by a manipulation that is introduced by the researcher. In addition, it provides information regarding how those factors may be caused by a manipulation that is introduced by the researcher (such as a programme, treatment, or change in the environment). By using this map as a tool to assist in understanding the data that the researcher has gathered, the researcher will be able to arrive at sound conclusions on the results of the study.

9) Analytical and accurate: The focus of a research project should not only be on what is happening, but also on how and why a certain event or process draws specific conclusions. This should not be confused with just "what is happening." If any of the data collected is worthless, either because it does not offer the intended conclusions or because it cannot be used in later research or applications, then the purpose of the study will be rendered moot and the study would have been a failure. As a consequence of this, the data that is acquired has to be precise while also being acceptable in order for it to be straightforward to analyze.

The degree to which the myriad of research procedures, equipment, and tools are related to one another is another aspect of accuracy. Accuracy also takes into account whether or not the research instruments and processes were selected in the most optimal way possible and whether or not they are appropriate for the research topic. Accuracy also takes into account whether or not the research topic is appropriate for the research instruments and processes.

It is very essential to the accomplishment of a research endeavour that the appropriate tools for data collection be chosen.

In contrast to being asked to provide feedback verbally, requesting written feedback from customers, such as with a Guest Comments Card in hotels or a Feedback Collection Card in dining establishments, provides customers with the opportunity to provide candid feedback regarding the quality of the services they received. This feedback can be used to make improvements to the customer experience.

10) Credibility: This is the tenth and last criterion, and it relates to the degree to which a study's results may be viewed as being trustworthy. Credibility measures how much a study's findings can be trusted. Research conducted using the most trustworthy methods and with the most trustworthy sources of information is the only way to provide a 100% assurance of this result. The reliability of research that is predicated on secondary data is severely compromised due to the fact that the data may have been manipulated or skewed by earlier researchers in order to conform to the findings of those researchers. As a direct consequence of this, research based on secondary data is not trustworthy. These documents could have been misplaced or erased totally. It is not difficult to collect secondary data by relying on information published in public domains; but, doing so brings with it a large element of risk. Studies that are carried out on the basis of primary data are always more credible and trustworthy than studies that are based on secondary data. This is because primary data are collected directly from the source of interest. It is feasible to use some secondary data in the event that the main source cannot be accessible; nevertheless, it is not prudent to base an inquiry solely on secondary data when it is viable to acquire primary data. Because of this, the research's credibility is diminished. If the researcher uses genuine references in the research, then the credibility of the study will increase. On the other side, the credibility of the study will decrease if fraudulent references are used in the research.

11) It is important to do an in-depth and critical analysis of the procedures and methods that were used in the course of a research inquiry. The process that will be used to carry out the study has to be entirely trustworthy and free of any possible issues that might arise. The approach that was decided to take and the actions that were taken needed to be able to withstand careful inspection in order to be successful.

Standards for Acceptable Research

Every day, fresh information is gained in a variety of academic subjects, and the fruition of fruitful academic research is the source of all of this new information. According to the National Science

Foundation, the amount of research conducted worldwide in only the fields of science and engineering has increased at an annual pace of around 4 percent over the last decade. Each year, there are more scientific and technical conference papers and journal articles that have been published thanks to the quality of the research that is being conducted.

The process of doing research for an academic paper entails more than merely deciding on a subject, gathering data, and interpreting it. Research has to fulfil a number of prerequisites before it can be deemed credible. By providing a list of the requirements for such research, the purpose of this article is to provide a response to the question "What are the features of excellent research?" It is my hope that this advice would be of use to researchers in ensuring the quality of their work.

Research has become an important tool for us to use in our efforts to better understand the state of affairs in the globe. It is predicated on the belief that the universe is a cosmic system, the events of which are governed by forces and interactions that can be articulated in the form of rules and fundamentals, and that these systems can be described as having causes. The implicit belief that the universe is a cosmic system is what underpins the Big Bang theory. As a kind of a hunting licence, the knowledge that nature imposes these limitations on us gives us the green light to search for strategies that will allow us to exercise control over our environment.

However, the research methods that are now available to us are not nearly as good as they might be. In the course of humanity's drawn-out march toward civilisation, it has taken it thus long to uncover only three key means for getting closer to the truth: authority, logic, and controlled observation. These approaches are as follows: Up until around 300 years ago, the majority of investigations into uncovering the truth focused significantly on the application of reason and showing respect to those in authority positions. Since that time, academics have placed a greater emphasis on carefully controlled observation that is supported by the reasoning of mathematics.

However, many of the natural phenomena that we are interested in examining do not lend themselves readily to any combination of the

three research methodologies that are currently being used. This is something that we are working to address. There are certain aspects of the reality for which there is no authority anywhere in the world, just inadequate methods of mathematical reasoning, and no procedures of controlled observation that are known to exist. It is true that the growth of research procedures and their subsequent refinement are gradually widening the field of inquiry. This is due to the fact that both of these processes are occurring simultaneously. On the other hand, the closer we get to exposing some part of the truth, the more broad the realm of the unknown seems to become. This is because the truth is not static. Due to the limitations discussed above, research very rarely enlightens us with all there is to know about a subject. The revelation of anything that initially appears to be the truth about the nature of some aspect of the process of learning almost always reveals itself to be merely a rough approximation of the reality at a later point in time. This is because the nature of the learning process is inherently unpredictable. When a new instructional method is established, it usually always turns out, after more research, that although it first seems to have universal application, in reality, it only has limited utility. This is the case despite the fact that it initially seems to have universal applicability. Because of this, it seems more advisable to interpret the findings of the research as a method of approaching the truth rather than as a means of revealing the absolute truth. This is because there is no such thing as an absolute truth.

When compared to the results of other studies, the quality of a particular piece of research will be able to assess how closely its findings fit the reality. Due to the fact that the quality of research efforts might vary quite a bit, a problem of major significance is the question of how much trust can be placed in the appropriate manner in the findings of a particular study. The primary purpose of this essay is to present a handful of criteria that are founded in common sense and have the potential to assist practical schoolmen in distinguishing between research that deserves a fair amount of faith and research whose conclusions should only be accepted with misgivings. This will be accomplished by comparing and contrasting the two types of research.

1) A research problem that is clearly defined: It is essential that the purpose of the study, in addition to the nature of the problem that is being investigated, be specified in as few words as possible while still maintaining as much clarity as is practically possible. This is one of the most important aspects of the research problem.

You should include an analysis of the problem into its most basic components, as well as its scope and constraints, as well as full descriptions of the meanings of all terminology that are necessary to the study, in the description of the research issue that you will be doing. If the researcher does not accomplish this in a suitable manner, there is a possibility that the readers will have valid reasons to question whether or not the researcher has a sufficient comprehension of the issue to devise an effective strategy for addressing it. In other words, if the researcher does not accomplish this in a suitable manner, the readers will have valid reasons to question whether or not the researcher has a sufficient comprehension of the issue

In order for the results of the study to be reproduced by another researcher, the methods for carrying out the research should be described in as much detail as possible.

2) A keen eye for detail: Research reports ought to describe the sources of data and the methods that were used to gather them in a manner that is honest and open, with the exception of circumstances in which secrecy is required to protect the national interest. In such circumstances, the information should be withheld. Due to the omission of essential methodological components, it is either difficult or impossible to assess the authenticity and trustworthiness of the data, which, in turn, damages the reader's confidence in the research for reasons that are completely acceptable.

3) A thoroughly designed research design is required in order to give results that are as objective as is humanly possible. The methodological framework for the study has to be properly constructed in order to accomplish this.

When there is a requirement to collect a sample from a population, the report should include information related to the degree to which the sample is representative of the population. In other words, it should show how closely the sample matches the characteristics of

the population. When there is more trustworthy material available, either from documentary sources or from direct observation, using a questionnaire as a research tool is not the proper choice. It is necessary for bibliographic searches to be conducted in the most thorough and comprehensive way that is technically possible. In experiments, controls have to be designed such that they are appropriate for the task at hand. After the event in issue, direct observations need to be put into writing as soon as it is humanly possible to do so. When selecting and recording data, there should be attempts made to mitigate the impact of personal bias to the greatest extent feasible.

4) Report any and all flaws in the research: The researcher is obligated to explain any faults with the methodological design in an honest and straightforward way, as well as analyse the influence such flaws have on the outcomes of the study.

There aren't very many methods of doing research that are completely foolproof. There is a potential that some of the defects may not considerably damage the validity and trustworthiness of the data, but others may make the data utterly untrustworthy. It is possible that some of the problems may not significantly influence the authenticity and trustworthiness of the data. An experienced researcher should be vigilant to the consequences of flawed design, and the researcher's competence in interpreting the data should provide him with a basis for appraising the relevance of these effects. [Case in point:] [Case in point:] [Case in point:] [Case in point:] [

5) An analysis of the data that is sufficiently competent: The study of the data has to be comprehensive enough to demonstrate the importance of the information, and the methods of analysis that are used need to be appropriate.

The amount of success that was obtained in achieving these criteria is often a reliable measure of the level of expertise held by the researcher. [Case in point:] [Case in point:] The author, who has over twenty years of experience supervising the research projects of graduate students, has arrived at the conclusion that the most challenging aspect of research for a novice researcher is the appropriate analysis of the data. This conclusion was reached after the author had come to the conclusion that the most challenging aspect of research for

a novice researcher was the proper analysis of the data. It is essential to do exhaustive tests to ensure that the data are of a high quality and can be relied upon. It is essential that the data be organised in a fashion that makes it simpler for the researcher to come at conclusions that are pertinent to the topic at hand. When making use of statistical methods, it is essential to take into account the possibility of making a mistake and to apply the standards for deciding whether or not a result is statistically significant.

6) Limiting Your Conclusions: It is important to limit one's conclusions to only those that are adequately supported by the findings of the study and to only those for which the data provide a sufficient foundation. It is also important to limit one's conclusions to only those that are adequately supported by the findings of the study.

Researchers are often tempted to incorporate personal experiences that were not subject to the circumstances under which the study data were gathered in order to expand the bases of inductions. This is done in an effort to extend the bases of inductions. This has the effect of making the research less objective, which in turn reduces the amount of faith that can be put in the findings. Equally unfavourable is the all-too-common practise of drawing conclusions from research carried out on a small sample and then extending those findings to the wider community as a whole. This is a practise that has a negative impact on both the community and the researchers. Researchers who are knowledgeable have pointed out in detail the conditions that must be met for their findings to be considered credible. In the event that this is not carried out, there is a fair foundation for a reduced level of confidence in the results.

If the researcher is well-established in the field and has a sterling reputation for honesty and fair play, then the results of the study will naturally carry more weight. If, in other words, the researcher is honest.

7) An experienced researcher is a plus: This criterion would possibly be one of the best bases for judging the degree of confidence a piece of research warrants if it were possible for the reader of a research report to obtain sufficient information about the researcher. This criterion would be a plus if it were possible for the reader of a research report to obtain sufficient information about the researcher. To put it another way,

whether the reader was able to get an adequate amount of knowledge about the researcher. As a result of this, the research report has to be accompanied with considerably further information about the qualifications of the researcher than is often the case.

Research Done in Universities

Every day, new knowledge is obtained in a wide range of academic fields, and the culmination of successful academic research is the source of all of this latest information. The National Science Foundation estimates that during the last decade, the quantity of research carried out in only the domains of science and engineering throughout the globe has expanded at an annual rate of around 4 percent. Because of the high quality of the research that is being carried out, there are ever more journal articles and conference papers in the fields of science and technology that are being published each year.

The process of doing research for an academic paper requires more steps than just settling on a topic, amassing relevant data, and providing an analysis of that material. Before a body of research can be considered reliable, it must first satisfy a number of necessary conditions. The objective of this article is to offer a solution to the question "What are the characteristics of good research?" by presenting a list of the needs for such study. It is my sincere wish that the researchers would find the following recommendations helpful in improving the quality of their work.

Characteristics of Reliable Research

1. A solid research subject is essential for doing successful research since it serves as the basis for the following:

Developing a research topic that is not only relevant to the problem at hand but also intriguing is one of the most important steps in doing productive research. In their work that was released in 2010, Farrugia and co-authors claimed that the process of developing a research subject is the phase that is the most important in the process of carrying out a research project.

An outstanding research question outlines, in excruciatingly minute particulars, just what it is that the researcher hopes to learn

about the topic at hand and defines the limits of the investigation's purview. Those doing research have the ability to ensure that they stay on track for the whole of their project by formulating a robust research question from the very beginning of their work. The research question, in the great majority of cases, has some type of effect onto the remaining acts that a researcher takes while performing their study in order to gather data for their investigation. On the other hand, developing a framework for a study issue is often more easier in principle than it is in practise. Because of this, several models like the FINER and PICO criteria have been established to guide researchers through the process of generating legitimate research questions. These models were developed as a consequence of the fact that researchers needed assistance in developing valid research questions. According to the criteria list, an effective research topic should include the following characteristics:

The letter "F" stands for "feasible."
The letter "I" stands for "interesting."
"Innovative" is what the letter "N" stands for.
The letter "E" stands for "ethical."
The letter "R" stands for "relevant."

2. Reliable research is always conducted in accordance with a planned and approved research methodology:

One of the most significant aspects that determines not only the overall quality of a study but also the degree of success it achieves is the methodology of research that was conducted for the study. The selection of a reliable research methodology is one of the most important steps in ensuring that researchers will be able to successfully collect relevant data and carry out the appropriate processes for data analysis.

The phrase "research methodology" refers to the systematic procedures or tactics that a researcher uses in order to ensure that his study provides accurate and trustworthy conclusions. This word was coined by the American Sociological Association (ASA). When classifying research methodologies, the most popular categories that

are utilized are quantitative research, qualitative research, and mixed-methods research.

The methodology known as qualitative research involves the collecting and examination of non-numerical data, such as language, with the goal of gaining insight into the beliefs, experiences, and behaviours of the people who are taking part in the study. The term "qualitative research methodology" refers to a range of approaches, some examples of which include interviews, focus groups, and case studies.

Quantitative research methods focus on uncovering patterns, investigating relationships, and developing hypotheses via the collection and analysis of numerical data. At the core of these methods is the collection and evaluation of numerical data. When conducting out quantitative research, some of the techniques that are available to choose from for the purpose of data collecting include surveys, experiments, and systematic observation.

Methodologies that combine qualitative and quantitative techniques are known as mixed methods. Mixed methods are used in research. Combining qualitative and quantitative research methods "permits a more thorough and synergistic exploitation of data than do separate quantitative and qualitative data collecting and analysis." This statement was made in reference to the fact that the combined method "permits a more thorough and synergistic exploitation of data."

Researchers need to take a number of different variables into account in order to pick the research technique that is the most suited for the topic that they are working on. The questions and objectives of the study, in the vast majority of cases, have a significant bearing on the choice of the research approach that will prove to be the most fruitful. In addition, it is essential for researchers to take into account the methods that are currently being used by other researchers in their specific field of study. For instance, recent study has shown that mixed-method research is gaining popularity in the area of health sciences. [Citation needed] [Citation needed] [Further citation is required] In their 2019 article titled "Mixed methods and survey research in family medicine and community health," which was published in the journal Family Medicine and Community Health,

Cresswell and Hirose observed how surveys were used in combination with focus groups on resident physicians' communication and collaboration competencies. The article was titled "Mixed methods and survey research in family medicine and community health." Therefore, in order to assess the competence of the IP physicians to offer feedback to paediatric residents while they were completing their rotation, the authors of the study by Sonnenberg et al. used an explanatory sequential mixed methods design. In the first part of this investigation, the researchers compared the communication styles of IP supervisors and physician supervisors. They also used survey research to determine whether or not the collaborative training objectives had been achieved.... After finishing the first phase of their study, the researchers went on to the second part of their project, which consisted of conducting follow-up qualitative focus groups in order to get a deeper contextual understanding of the factors that influenced the process of assessment.

3. Good research takes into account previous investigations that have been carried out on the topic in question:

To do excellent research, one must, in addition to leading to the collection of fresh material, become acquainted with the work that others have done on the same topic. When you read academic publications and other works that are connected to the topic that interests you, you may gain a sense of what previous research has been done on the topic and how your own research fits in with the findings of the previous research. This can help you determine how your own research fits in with the findings of the previous research. Investigating the results of studies that were conducted in the past may also be a useful way to ensure that you are not duplicating work that has previously been completed. The corpus of literature that is relevant to the topic at hand may also provide information about potential obstacles and difficulties that researchers could face in the course of their inquiries.

The majority of academic research projects, such as theses and dissertations, contain a literature review because of how vital it is to analyse research that is relevant to the topic that is being investigated.

This is the case because of how crucial it is to evaluate previous research. The aim of a literature review is to provide readers a full understanding of the topic at hand by describing and providing an unbiased evaluation of the academic papers, books, and other sources that are relevant to a certain field of study (Bloomsburg University of Pennsylvania, n.d.). According to the most recent version of The STM Report, which is an annual publication put out by the International Association of Scientific, Technical, and Medical Publishers, there were approximately 33,100 active academic peer-reviewed English-language journals as of the middle of 2018. This information was gleaned from the publication. The yearly article output of these publications is close to three million, and the annual growth rate of their circulation is around four percent (Johnson et al., 2018). It is quite improbable, in light of these figures, that researchers will have difficulty discovering published material that is pertinent to the topic of their investigation.

4. Reliable research makes use of data that is relevant and factual in addition to proper procedures for data analysis:

One of the most important characteristics to look for in a research study is whether or not it deals with empirical data, since this is a hint that the study is of high quality. Information that was obtained by the researchers themselves by techniques such as observation, experience, or experimentation is an example of the kind of data that is referred to be empirical (Bradford, 2017). This is an incredibly crucial component of doing high-quality research since empirical data is often seen as being proof that is both objective and unbiased.

The gathering of empirical data is just the first step in doing quality research; in order to produce findings that are of any value, the data collected first need to be processed in the proper manner. The kind of data that was collected is the primary factor that decides which method of data analysis should be used to the information. When analysing quantitative data, for instance, one of two types of statistics—descriptive statistics or inferential statistics—is often used (Humans of Data, 2018). Researchers may develop figures with the use of these statistics that summarise variables, find patterns, and make

predictions using the data. On the other side, the analysis of qualitative data comprises discovering patterns and themes within the textual data and offering an interpretation of those results. This is done in conjunction with presenting a summary of the findings. When dealing with qualitative data, it is common practise to use several forms of analysis, including content analysis, narrative analysis, and theme analysis (Warren, 2020)

In order to offer a response to the question raised by your research project, you may put these methods of analysis to work in order to examine either quantitative or qualitative data.

5. Reliable research should not only be able to be generalized but should also be reflective of the whole:

One of the factors for determining whether or not research is of high quality is whether or not it is representative. The potential of a sample to act as a stand-in for a larger population is what is meant by "representativeness" when used in the context of scientific investigation. This suggests that the characteristics of the individuals who are being investigated (the subjects) closely match those of the population that the research seeks to analyze.

Utilizing population sampling is, in the vast majority of cases, the most effective method for ensuring representativeness in research (Economic Research and Social Council, n.d.). Researchers have the ability to guarantee that their findings can be extrapolated to the larger population represented by the sample they establish if they use appropriate methodologies to create a representative sample. This allows the researchers to guarantee that their findings can be extrapolated to the larger population.

6. Good research is guided by sound reasoning, which acts as a compass:

One of the distinguishing characteristics that sets this endeavour aside from others is the use of logic across the board during the whole of the research procedure. For instance, utilizing logic may help researchers define what kind of data they require in order to answer the question that they are exploring for their study. This is something that

they are doing for their investigation. When researchers are guided by logic throughout the whole course of the study, it significantly improves their capacity to identify logical fallacies and inconsistencies in the claims and conclusions they draw from the data.

In addition to their possible applications, the logical processes of induction and deduction may also be of significant benefit in the process of doing research. Logic is beneficial to researchers since it makes it easier for them to draw believable conclusions from their findings. According to the results of the study, inductive reasoning may be used in the process of developing generalizations and hypotheses, as well as in the search for patterns that emerge from the data. In the meanwhile, the application of deductive reasoning may be of assistance to researchers in the process of gathering empirical information, which may subsequently be used to support or reject hypotheses or concepts.

In addition to these applications of logic, logical thinking may also make subsequent research more understandable. This is of utmost importance when the study is going to be used in the context of decision-making, which is why it is so crucial (Mehran University of Engineering and Technology, n.d.).

7. A good research project should be relevant to the larger world:

It is said that a piece of research has what's known as "external validity" if it can have its findings or conclusions put into practice in the real world (Glen, 2015). If the findings of your study can be generalized to apply to a wider range of circumstances or extrapolated to cover a broader range of circumstances, then your research is said to have high external validity.

When determining the extent to which their work has external validity, researchers need to take into account both the demographic validity and the ecological validity of their findings (Bhandari, 2021b). If the findings of a piece of study can be generalized from the sample to the larger population, then the population validity of that research is considered to be strong. In the meanwhile, you may achieve ecological validity if you are able to link the findings of your study to situations and environments that exist in the real world. This will demonstrate that your findings are applicable to the real world. Since acquiring

knowledge that can be used in a variety of settings is almost always the purpose of scientific research, ensuring that one's findings have external validity is a vital component of doing high-quality research.

8. Quality research should be able to be reproduced and should be subject to close examination:

Reproducibility, transparency, and the ability to be duplicated are three of the characteristics of research that are considered to be among the most important. The replicability of a research study determines whether or not the findings of that study can be independently verified by other researchers. This is one of the most important aspects of a research project. The ability of the findings of a study to be replicated by other researchers is one factor that might contribute to the study's credibility with the general public (Understanding Health Research, 2020).

Another defining characteristic of high-quality research is its ability to be reproduced. Although the terms "replicability" and "reproducibility" are sometimes used interchangeably, a piece of research can only be considered repeatable if the researchers who carried it out were able to arrive at the same conclusions each time they used the same data and analytical procedures. This is the only criterion that determines whether or not a study is repeatable. The ability of a research study to be reproduced and repeated, in addition to the study's results, may give proof of the study's general validity and trustworthiness.

Either the study has to be completely open and honest with its methods and findings, or it needs to be made readily available to other scientists so that it may be replicated. When research is written up or presented, it has to be done so in a way that provides comprehensive information on how the data was gathered and analyzed, as well as how the findings were formed (Baskin, 2015). As a result of this, the vast majority of scientific articles include in-depth descriptions of the research process to which they are relevant.

Different Kinds of Research

When conducting studies, researchers have access to a wide variety of methods, which are collectively referred to as "types of study." According on the goals, schedules, and motivations behind the study that is being carried out, several methods of research are more suited for certain types of investigations than others. The first thing that has to be done when planning research is determining what you want to look into and what you want to learn from it. You might, for instance, just be interested in acquiring additional information about a subject, or you might be interested in attempting to understand how a new policy would impact lower-level workers at your organization. Either way, there are a few reasons why you might have an interest in either of these things.

There are many industries and types of enterprises that might benefit from the use of various types of research studies, including the following:

- The academic fields that are associated with the scientific method, including chemistry, biology, and others
- Branches and departments of the state that are administered by the state
- For reasons pertaining to education
- Business necessity

The following is a list of 19 different types of research that you should consider when establishing your research methodology:

1) Qualitative investigation:

In qualitative research, nonnumerical data like opinions and books are employed instead of numerical data. Qualitative data examples include:

- Conversations in small groups
- Surveys
- Commentary from those who took part
- Observations
- Interviews

It is common practise for companies to do qualitative research to learn the opinions and reactions of customers. To receive feedback on a new advertisement before it is released to the general public, a marketing organisation, for instance, would first show it to a focus group. In order to make decisions, the company gathers information that is not quantifiable, such as the perspectives of people who participate in focus groups.

2) Quantitative investigation:

In quantitative research, examples of numerical data such as statistics and measures include things like measurements and statistics. For example, a car manufacturer may look at the number of red cars sold in comparison to the number of white sedans sold. The research derives results based on actual data (sales figures for red and white autos) (sales numbers for red and white automobiles).

3) Fundamental Research:

The purpose of fundamental research, often referred to as basic research, is to aid academics in gaining a greater understanding of certain occurrences that occur in the world; this kind of study investigates how things function. Your understanding of scientific concepts and explanations will perhaps improve as a result of participating in this research. For the purpose of doing fundamental research, a corporation may, for instance, investigate the impact that varying product placements have on product sales. This study is knowledge-based and provides data at the same time.

4) Research that can be put to use:

The purpose of applied research is to find solutions to existing problems or give responses to existing worries. The purpose of the research is to produce knowledge that can be put to use that is both relevant and pertinent. For instance, a study on how to increase the amount of student engagement in the classroom may be an example of applied research. This research looks at potential solutions to a particular problem, as well as the issue itself.

Both basic and applied research are considered to be the two primary types of research. The nature of most research may be

categorised as either fundamental or applied, according on the questions it seeks to answer.

5) Longitudinal studies:

A longitudinal research follows the same group of people through time but makes no adjustments to any of the other variables. For instance, a researcher may explore whether or if and how the level of satisfaction experienced by employees who have been employed by the same company for one, three, and five years changes over time.

6) A study using a cross-sectional design:

A cross-sectional study is one that takes a snapshot of a population or sub-population at a specific point in time. Researchers often choose participants based on shared characteristics like as age, gender, or wealth, and then analyse the similarities and differences that exist within each group as well as across the groups. A larger population is often represented by the group in discussions. Researchers investigate individuals in a manner similar to that of longitudinal research, in which factors are not altered.

For instance, a company may look at the sales tactics used by the top 10 percent of its salespeople and compare them to the tactics used by the worst 10 percent of its salespeople. This may be of assistance to the company in gaining knowledge regarding the sales strategies that are most effective and those that are least effective.

7) Research using a combination of methods:

Research that is mixed draws from both qualitative and quantitative sources for its findings. Take into consideration the OEM tracking sales of sedans. The company may also request that clients take out a survey after buying a red or white vehicle, in which they will be asked how much the colour impacted their decision as well as other open-ended questions.

Investigative research number eight:

When doing exploratory research, one considers not just what is already known about a topic but also what new information there may

be. It is more likely to give a general grasp of a subject as a springboard for additional research than to provide specific answers to queries that have been posed. Exploratory research is often conducted on subjects and phenomena that are not well recognised.

Take into consideration what is now known about the efficacy of maternity and paternity leave programmes that last for a whole year. For the sake of this research, it may be necessary to compile all relevant information and provide it in a format that was not previously available but is now. Your inquiry could turn up certain knowledge holes, which would make more investigation in the future necessary.

9) An inquiry on the field:

Research in the field is done "on site," which means it takes place wherever the participants or subjects are. For this kind of research, on-location observation and data collection are both required. For instance, a manufacturing business may hire an environmental engineering firm to evaluate the air quality inside the facility to ensure that it satisfies all of the standards for health and safety. In order to collect samples, the scientists would go to the factory.

10) An inquiry in the laboratory:

The controlled atmosphere of a laboratory is where research is carried out, as opposed to being carried out in the wild. A strict commitment to the established limits, such as the removal of variables or the criteria for scheduling, is often required for the study. Laboratory research might include things like conducting experiments in the pharmaceutical and chemical industries.

11) A comparative investigation:

A comparative research attempts to determine the degrees to which two individuals, subjects, or organizations share and differ from one another. When an owner, for instance, reviews the documents pertaining to new hire training, they might notice that new employees receive a significant portion of the same training both during orientation and their initial training with their respective departments.

To afford more time for department-specific training, the owner may chose to bundle all similar training into orientation papers.

12) The research of possible causes:

The objective of causal research, which is often referred to as explanatory study, is to establish relationships of cause and effect between different variables. The purpose of this research is to identify the degree to which one variable may impact another one. Research on causes is essential for evaluating existing processes and procedures, determining whether or not changes should be made, and determining how those changes should be implemented.

For instance, a company could compare employee retention rates before and after implementing a work-from-home policy after the first six months of employment in order to determine whether or not the policy improves employee retention. This comparison would take place after the company had offered employees the opportunity to work from home.

13) Investigative method known as induction:

The objective of inductive research, often referred to as theory-building research, is to collect data that may be used as a contributing factor in the formulation of a new hypothesis on a certain process or event. This kind of research examines data and trends, then puts up a variety of hypotheses to explain the findings. The scope of an inductive investigation expands as it moves from the specific to the general.

Inductive research is often used in the process of theory generation, and it frequently results in the need for more study, such as deductive research, in order to investigate prospective concepts.

Researchers may discover, for instance, that the year 12 multinational companies introduced in-house carbon emissions controls, worldwide emissions declined. This may be a correlation that they find interesting. The researchers may postulate that if multinational corporations implement in-house emissions controls, worldwide emissions may be considerably cut.

The progression of inductive research is from the general to the specific, while the progression of deductive research is from the

general to the specific. Researchers first construct a hypothesis, then put that hypothesis to the test by conducting experiments or making observations.

Take, for instance, the example of global business emissions standards that was presented earlier. In order to test this theory in a manner that is consistent with logic, one should do research that compares the levels of global emissions both before and after the implementation of emissions limitations by multinational firms.

14) The inquiry will be fixed:

Fixed research comprises experiment methods that are defined in advance, such as how often testing will occur, where testing will place, how many persons will be tested, and the types of subjects that will be tested on. The study relies on specific circumstances and strict adherence to predetermined methods in order to reduce the amount of variation. Research that is fixed in its nature is typically more reliable and reproducible than research that is flexible.

The term "experiment" is frequently used interchangeably with "fixed research." A researcher, for instance, might investigate the impact that altering labels has on the opinions that consumers have regarding a particular brand of sports drink. Aside from the label, the researcher has to make an effort to control any and all other elements that could have an impact on how the participants evaluate the beverage. At the same time, participants are given the same beverage but with a different label, and they are then tasked with filling out a questionnaire assessing the flavour as well as their overall thoughts. The validity of the research is heavily dependent on the timing of each beverage as well as the questionnaires that came after it.

15) Research That Is Adaptable:

During the course of a flexible research study, the procedures may be subject to change. There are many different kinds of flexible research, including the following:

Case studies are detailed examinations and observations of a single person, group of people, or issue. In the field of anthropology, ethnography refers to the practise of doing in-depth research and

observations on a certain population. Investigations based on the grounded theory aim to construct ideas by painstakingly gathering and analysing evidence from a variety of sources.

16) Research involving participants in active participation:

Action research is the process of investigating your actions, assessing their effectiveness in accomplishing the desired purpose, and deciding on a course of action based on your results based on the findings from your action research. Action research is often applied in educational settings to assist educators and administrators in conducting self-evaluations and making necessary adjustments to lesson plans.

For instance, a teacher may compile information on the methods they use to instruct fifth-grade mathematics. At the end of the first school quarter, the teacher could discover that only one-third of the students displayed competent performance in the topics they were studying. As a direct result of this, the instructor of the fifth-grade mathematics class implements new tactics during the second quarter of the school year.

17) An examination of the policy:

The purpose of policy research is to either investigate the effects of pre-existing policies enacted by the government or by social institutions, or to foresee the potential implications of new policies in terms of how they will affect the distribution of available resources. Researchers that focus on policy are often employed by government entities and do the following types of research:

- An evaluation of the costs and benefits
- Carry out an examination of the cost-benefit ratio.
- Evaluation of the programme
- Analysis of requirements
- Investigation into classification

In classification research, individual components of a group are isolated and placed into larger groups or subgroups based on their

shared characteristics. For instance, biologists investigate animals and classify them according to shared characteristics like the following:

- Segmentation of the body
- Habitat classification
- Methods and means of procreation
- Diet

18) A comparative investigation:

A comparative research attempts to determine the degrees to which two individuals, subjects, or organizations share and differ from one another. When an owner, for instance, reviews the documentation pertaining to new hire training, they could observe that new employees get a significant portion of the same training both during orientation and their first training with their respective departments. Consolidating all similar training into orientation papers may be a choice that the owner makes in order to free up more time for training that is specialized to certain departments.

19) The study of the causes:

The objective of causal research, which is often referred to as explanatory study, is to establish relationships of cause and effect between different variables. The purpose of this research is to identify the degree to which one variable may impact another one. Research on causes is essential for evaluating existing processes and procedures, determining whether or not changes should be made, and determining how those changes should be implemented.

For instance, a company could compare employee retention rates before and after implementing a work-from-home policy after the first six months of employment in order to determine whether or not the policy improves employee retention. This comparison would take place after the company had offered employees the opportunity to work from home.

20) Inductive investigation:

The objective of inductive research, often referred to as theory-building research, is to collect data that may be used as a contributing

factor in the formulation of a new hypothesis on a certain process or event. This kind of research examines data and trends, then puts up a variety of hypotheses to explain the findings. The scope of an inductive investigation expands as it moves from the specific to the general.

Inductive research is often used in the process of theory generation, and it frequently results in the need for more study, such as deductive research, in order to investigate prospective concepts.

Researchers may discover, for instance, that the year 12 multinational companies introduced in-house carbon emissions controls, worldwide emissions declined. This may be a correlation that they find interesting. The researchers may form the hypothesis that if multinational corporations implement emissions regulations inside their own facilities, there would be a significant drop in worldwide emissions.

The progression of inductive research is from the general to the specific, while the progression of deductive research is from the general to the specific. Researchers first construct a hypothesis, then put that hypothesis to the test by conducting experiments or making observations.

Take, for instance, the example of global business emissions standards that was presented earlier. In order to test this theory in a manner that is consistent with logic, one should do research that compares the levels of global emissions both before and after the implementation of emissions limitations by multinational firms.

UNIT 2

IDENTIFICATION OF RESEARCH PROBLEM

The exploration of scientific questions has several aims, two of the most important of which are broadening people's perspectives and shedding light on the truth. Participation in research, which leads to the development of theory, is an absolute need for academics if they are to realise this goal.

Both forecasting the future and comprehending it are essential components of theory, and the two tasks typically and always go hand in hand with one another. Predicting and understanding the future go hand in hand with one another. To be able to make a forecast, one must first know and comprehend why the variables act in the manner in which they do. Theories provide an explanation as to why the variables behave in a certain manner. A cohesive set of general assertions that are used as guiding principles in order to explain the apparent links of particular observable events is the definition of a theory. Theories may be found in many different fields of study. A theory is defined as a set of broad assumptions about a subject. The development of hypotheses and the subsequent testing and refinement of those hypotheses is carried out via a sequence of steps that make up the scientific method.

Concepts serve as the foundation for the method in which scientists approach their job as well as the way in which they think. Creating concepts is the first step that has to be taken for people to be able to think about and express abstract thoughts. In order to provide specialised explanations of occurrences that cannot be directly seen, the scientific community makes use of ideas that are on a higher level. On the level of the conceptual and the construct, concepts and constructs are employed, whilst on the level of the empirical, variables are utilised. In the course of carrying out research in a scientific field, a great number of hypotheses are developed and then put to the test via the use of inductive and deductive reasoning, in addition to reflective thinking. In the scientific community, research is conducted in

accordance with a methodical approach that conforms to a standardised procedure that integrates induction, deduction, observation, and the testing of hypotheses into a sequence of actions that include reflective thinking. The approach in question is often referred to as the scientific method.

Individuals have varied ways of assessing situations owing to the fact that they have diverse perspectives on the world and have been conditioned in various ways by the environment that affects them; as a direct consequence of this, the kinds of questions that people ask also vary. Investigating potential solutions to issues via the use of scientific methodology is one possible approach to issue resolution. It will be to the benefit of the researchers to have a better understanding of the link between scientific research and research in general when they are developing the study.

SCIENTIFIC METHOD

There is a possibility that throughout the course of time, the definition of "science" will grow increasingly explicit. It makes an effort to describe the circumstance in a manner that is true to life, which it successfully achieves. In the end, it is a strategy for the generation of new knowledge, and this strategy may take the form of an organisation or a system. But ultimately, it is a strategy. The scientific method is one of the many things that have been generated as a result of the system.

The vast majority of people are aware that science may be segmented into two separate subfields, which are known as hard science and soft science respectively. Hard science encompasses both biological and physical sciences (human science). The questions that are asked by science play a substantial part in figuring out the approaches and methods that are used to scholarly inquiry, as well as the tools and resources that are made use of. In the world of academia, one of the most common strategies for achieving the objective of achieving new levels of knowledge is to use what is known as a scientific approach. Research conducted in the area of business is considered to be scientific since it adopts a method that is objective when evaluating the processes and linkages that are inherent to the

world of business. Included in this section is research conducted on a wide range of topics, including those pertaining to education, information and communication technology, and others.

To arrive at generalisations that can be believed and that are backed by data, as well as to establish the relationships that exist between the various variables, are the major aims of the scientific method. When scientists have a complete understanding of the relationships between phenomena, they will be able to comprehend a phenomenon in terms of the patterns of connections, they will be able to make predictions about the phenomenon, and they will be able to discover the causal linkages that exist between the phenomena. When scientists have a complete understanding of the relationships between phenomena, they will be able to comprehend a phenomenon in terms of the patterns of connections. The scientific method is absolutely necessary for reliable scientific practise, and reliable scientific practise may be recognised by searching for the following characteristics in the practise:

(a) It is empirical, which means that its validity is determined by how closely it corresponds to the world as it really exists;
(b) it is repeatable or objective, which shows that the perspective of the researcher is independent of the findings and that other researchers who did the study would obtain the same results;
(c) it is analytical, which means that it dissects and explains empirical data in accordance with the procedure outlined by the scientific method;
(d) it is theory driven, which means that it is based on a body of knowledge that has already been established; and
(e) it makes sense, which suggests that it is necessary to underline the fact that the degree of control over confounding factors is what differentiates rigorous research from other types of scientific inquiry that are not as rigorous. For instance, in the world of business, there are a great deal of circumstances that are outside the control of managers. As a consequence of this, there is a need for some kind of middle ground to be found between the strict criteria of science and the practical issues of running a business in the real world. It is required for

there to be some kind of agreement established that fulfils both the interests of people involved in business and the wants of those engaged in research. This is because it is necessary for there to be some kind of agreement created.

Even if this will result in errors, the research should still proceed with the creation of the information as long as the researcher advises the decisionmaker of the constraints, and the results are qualified based on how the restrictions were dealt with. Even if this will result in mistakes, the research should still proceed with the creation of the information. An excellent scientific investigation will also adhere to the concept of parsimony, which states that it is preferable to find a solution that does not involve an excessive amount of complexity. This concept asserts that it is better to discover a solution that does not involve an excessive amount of complexity. When doing research, it is essential to keep an understanding that is as basic as is reasonably feasible while simultaneously ensuring that any questions that are raised may be answered in a way that is to the researcher's satisfaction.

TRADITIONAL SOURCES OF KNOWLEDGE

The acquisition of new information and the expansion of one's existing knowledge are two goals that may be achieved by using any one of a myriad of different approaches and procedures. The knowledge that is gained through traditional sources is not obtained by scientific techniques; as a result, it is likely that this information is erroneous. The following is a list of typical examples of places where one may get information:

a) Relying Too Heavily on One's Sense Perceptions

It is feasible to acquire information and knowledge by depending on what is publicly known and what is consistent logically. [Citation needed] [Citation needed] This is one possible approach. Even while having common sense may be helpful in day-to-day life, if it isn't put to good use, it might leave one's thinking open to logical fallacies. This is especially true if common sense isn't analysed critically. As a consequence of the fact that these ideas are employed at various periods, many people may not be aware of the fact that common sense

includes views that are in direct contrast to one another. This is because these ideas are utilised at different times. One of the places where common sense may be found is in tradition; this kind of information may be useful, and it may even be genuine, but it also may include mistakes, disinformation, and contradictions. It is quite likely that the prejudice originates not just from thinking but also from disparities in society and culture. Recognizing the reality that one is lacking in particular areas of common sense knowledge is one way to reduce the likelihood of making judgments that aren't in one's best interests. This is accomplished by the use of the phrase "acknowledging one's lack of common sense knowledge."

In order to close this information gap, one must first generate the appropriate sort of information, and then one must rigorously assess knowledge that is considered to be common sense in order to identify the root cause of the problem. Both the establishment of experiments for the purpose of conducting systematic testing and the ongoing collection of data in order to investigate the recurrence of an event are viable options for determining the underlying factor (or factors) that are responsible for a phenomenon. Continuing to collect data in order to investigate the recurrence of an event is an important step in the process of determining the underlying factor (or factors) that are responsible for Systematic testing may be carried out by monitoring the outcomes of several repetitions of the event and recording the findings. As a direct and immediate result of this, recent developments in scientific knowledge are integrated into scientific

In the context of the scientific community, what traits are necessary for valid research?

In this part of the self-test, rather than depending just on one's own common sense, the need of doing research is emphasised. The gathering of the right sort of information could be accomplished by conducting an investigation that is extensive and meticulous.

(b) Personal Experience

When something happens to you, you not only have the opportunity to feel it, but you also have the chance to experience it, and in the end, you come to the realisation that it is true. When something

happens to you, you have the opportunity to feel it, experience it, and come to the conclusion that it is true. The phrase "seeing is believing" relates to one of the most powerful sources of information, which is the individual's own firsthand experience. Direct experience is one of the most strong forms of knowledge. On the other side, a person's very own experiences have the potential to steer them in the wrong direction. What may seem to be true might, on closer inspection, be the result of a little lapse in judgement on the part of the individual or a warping of their point of view. The human species has a high propensity for error and is susceptible to being duped by many illusions. They may put their faith in what they see or experience, despite the fact that such data may be rife with inaccuracies, and this may be to their detriment. Even if they are aware of the danger of making such mistakes, it is possible for this to still occur. My own personal experiences have shown me how important it is to steer clear of making these four critical errors in judgement:

I When people come across evidence that backs up what they believe, they have a propensity to presume that this evidence can also be applied to a wide variety of other scenarios as well. This is because most people prefer to believe what they see rather than question it. Because people have little or no knowledge about a wide variety of other people, topics, and circumstances, it may seem fair to them to draw generalisations based on the information that they do have access to.

(ii) An example of selective observation is when individuals pay more attention to certain other individuals or events than they do to others in order to draw conclusions about a larger population or phenomenon. This is done in order to draw conclusions about the phenomenon. People are more sensitive to characteristics that support their beliefs; as a consequence, their attention is directed more intently to aspects of the reality that match to their preconceived concepts. People are more sensitive to qualities that support their views. [The chain of causation] People pay more attention to qualities that provide credence to the perspectives they hold.

(iii) Untimely closure: This error often occurs in combination with some of the other two flaws, and it serves to reinforce both of

those flaws. This mistake is one that should be avoided at any and all costs. When someone reaches the opinion that they have already learned all there is to learn about a topic and that it is no longer essential for them to listen, seek information, or ask questions on that topic, they have attained a premature closure. When someone have an erroneous sense that they have all the answers to a topic, it's possible for this to happen to them.

(iv) The halo effect is a phenomenon that may manifest itself in a wide variety of distinct ways. It is the tendency of people to make an excessive amount of conclusions based on what they believe to be particularly advantageous or prestigious, and it is referred to as the inference bias.

PHILOSOPHY OF SCIENTIFIC RESEARCH

The two major pillars that support the structure of the scientific method are logical reasoning and the careful observation of events that occur in the actual world. In order for a scientific explanation to be regarded genuine, it has to not only make sense (be logical), but also fit in with what we can see and experience. The reality that we see may be validated via the use of observation and the amassing of data through the collecting of measurements of what can be observed in the world. Both are crucial elements of the scientific method, each of which is connected to one of the three fundamental pillars that serve as the foundation for the scientific community:

On the basis of this provisional theory, it is feasible to draw further hypotheses and predictions with the intention of doing more study or testing. Continued investigation or testing will be carried out until the hypotheses and guidelines that were developed have been perfected to the extent that they can realise their full potential. At this point, any rules or ideas that have been honed to a more refined form are only educated assumptions. Adjustments will need to be made in the event that it is discovered that a new observation does not readily fit into an existing body of knowledge, or if it is shown that the theories or laws are erroneous. The process will continue to repeat itself in a cycle that never reaches its conclusion whenever new information is gained as a direct consequence of fresh observations.

DEDUCTIVE AND INDUCTIVE MODELS

The application of theoretical frameworks to issues that occur in the actual world is essential to the conduct of research and would not be feasible without it. A clear declaration of a theory may or may not be included in the process of organising a research endeavour; nonetheless, ties to theories will be exposed openly throughout the presentation of data and the conclusion.

(a) Model The method through which basic rules are formed from specific evidence is referred to as the inductive reasoning paradigm. The process of deriving anything begins with the particular and then moves on to the general; it begins with the gathering of specific data and ends with the recognition of a pattern that implies there is some sense of consistency among all of the provided events. The process of deriving anything through induction begins with the particular and moves on to the general.

(b) a model that is constructed via the use of the method of deduction The logical paradigm in which precise expectations of hypotheses are derived from general principles begins with a pattern that can be logically or theoretically predicted and then moves on to observations that test whether or not the anticipated pattern actually happens. The next step in the process is observations that test whether or not the anticipated pattern actually happens. starts with a pattern that can be expected logically or theoretically and then moves on to observations that test whether or not the anticipated pattern really occurred. proceeds from the general to the specific by beginning with a pattern that can be predicted logically or theoretically. A pre-existing theory is used as a jumping off point in the deductive process, which is used to determine what sort of hypothesis should be tested. After that, the hypothesis is tested utilising data gleaned from the field as the main source of information in an attempt to disprove it via an empirical investigation. Following the completion of the data analysis, the hypothesis is contrasted with the results to determine whether or not the latter provide confidence to the former's precision. In the case that the facts do not support the hypothesis, then it is required to reject the hypothesis since it is not grounded. This is because the hypothesis is not supported by any evidence. If the results are consistent with the

anticipated outcomes, then the hypothesis may be said to be valid. [Clarification needed] As a direct result of this, theories are altered so that they are compatible with the facts that have been uncovered.

An observation is collated within the context of the inductive model in order to aid the construction of an initial notion, which eventually adds to a deeper grasp of a phenomena. This is done in order to further one's understanding of the phenomenon. After that, the method is used to the process of developing more relevant research questions, which, after that step has been finished, will be helpful for the process of gathering data in the future.

The findings are analysed to determine whether or not the primary premise was correct. [Further citation is required] The idea that has been shown to be effective serves as the basis for the construction of the new theory, which is created on top of it. Following that, the original hypothesis is analysed by considering it in light of an existing theory. If it can be proven that an existing hypothesis is reinforced or confirmed by a new theory, then the present hypothesis is said to have been verified or strengthened, depending on which of the two outcomes was achieved. In the case that the comparison shows any inconsistencies, the hypothesis that is currently accepted will be altered in order to take into account the new information that has been discovered.

LINKS BETWEEN THEORY AND RESEARCH

Concepts, definitions, and hypotheses that are systematically related with one another, in addition to those that are put to use in order to explain and anticipate occurrences, are regarded to be the essential parts of a theory (facts). It is a logical justification for making the observation, and it relates to a particular aspect of the activities that a person partakes in. On the basis of theories, every function is carried out since theories are broad claims about variables and the relationships between them. This is because theories make comprehensive statements concerning a variety of factors. After that point, judgments and projections of future occurrences are generated from the inferences that were taken from these overarching generalisations. In the realm of

academic study, theory has the potential to be useful in accomplishing a wide variety of goals, including the following:

It helps to reduce the scope of the facts that need to be studied and makes it possible to study any subject using a broad variety of methods. a. It cuts down on the quantity of facts that need independent investigation. b. It's feasible that a theory will be able to steer us in the direction of the procedures that are most likely to yield the highest relevance;

(b) it has the potential to provide the researcher with a framework that may be used to apply to the acquired data in order to meaningfully categorise the information;
(c) It may include a synopsis of the information that is currently known to them about a certain item.
(e) It assists with the prediction of future facts that may be revealed, and (d) it draws attention to patterns that are not immediately apparent.

A problematic circumstance uncovered by the study on marketing

Challenges posed by marketing research are used by organisations and enterprises in order to ascertain the amount of risk that is associated with the launch of a new product or service. They do not want to make an investment in expanding a product line if analysis shows that there is a low probability of the line becoming profitable. It is useful to do marketing research that is both well-designed and well-executed in order to aid in making judgements about the product or service, especially if the study is conducted online. This makes it easier to determine the likes and preferences of customers as well as the interests of customers.

Contacting a faculty member or research worker who has a larger degree of competence is a beneficial practise, despite the fact that research subjects should not be assigned, nor should they be suggested and allotted by a guide. One of the most important things that the research guide does is help the student clarify his thoughts. It also helps the student gain a sense of focus and construct a manageable problem from one that may be too vague and too difficult.

This is one of the most important goals that the research guide is trying to accomplish. A Glance at the Previous Investigations

• A literature review is a comprehensive compilation of the information obtained from published and unpublished sources of data in a specific field that is of interest to the researcher. the information may be found in the particular area that is of interest to the researcher.
• A "literature review" is a systematic, transparent, and repeatable strategy for identifying, evaluating, and interpreting the existing corpus of recorded materials. This kind of approach is known as a "review of the available literature." The goal of this review is to

i) Get some background information on the subject of the research.
ii) Identify ideas and linkages associated with it, and propose hypotheses that are amenable to inquiry.
iii) Determine the approach, study design, methodologies, and procedures that are suitable for the analysis.
iv) Determine the data sources that have been utilised by other researchers
vi) Obtain an understanding of how other people have organised their reports for review purpose ii) Learn some background information about the subject of the research.
vii) Determine the ideas and connections that are associated with it, as well as the works of literature that will be investigated and the rationale for the study.

UNIT 3
RESEARCH DESIGN

It includes an outline of what the researcher will do from writing the hypothesis and its operational implications to the final analysis of data. A research design is the conceptual structure within which research is conducted. It constitutes the blueprint for the collection, measurement, and analysis of data. Components that Make Up a Research Plan A plan is what's known as the research design, and it outlines the many information sources and kinds that are pertinent to the study challenge. It is a plan that outlines the methodology that will be used in the process of data collection and analysis. In addition to that, it incorporates the cost and time budgets.

Steps/stages in developing a research design

The phases in the design of the research are as follows:

1. **The definition of the problem and its parameters**: This is the first phase, and it begins with the definition of the problem. Following an analysis of the relevant literature and a comprehension of the current circumstance, a potential area of the issue has been identified. The study's goals and objectives are being developed. This is the beginning of any research project, which will determine how additional study will go.
2. **Developing a framework for the research design -** The research framework is developed based on the goals of the study and the nature of the variables. It specifies the action plan for collecting data and doing analysis.
3. **Sample design -** The next step is the design and selection of samples. At this point in the process, the researcher is responsible for determining whether a census or sample study is to be carried out, as well as the sampling procedures that will be used.
4. **The gathering of data-** It is important to predetermine the sources and procedures that will be used to collect data in order to prevent collecting data that is not relevant and wasting time.

In order to attain reliability and validity, the techniques, sources, and instruments used to gather data should be chosen using a scientific approach. It is important to identify both the main and secondary sources of data.

5. **Analysis of the data-** Once the data gathering has been finished, the data will be sorted and organized appropriately to make further analysis easier. After the data has been obtained, it is next subjected to editing, coding, and decoding. Different approaches to analysis are used for qualitative and quantitative data, depending on the characteristics of the data being analyzed.
6. **Writing a report -** A report that is inclined towards research is a reflection of the research activity that was done. The value of a research study may be improved by reporting that is straightforward, unambiguous, and objective. Reports are beneficial to future research, because they broaden the scope of the study field. In order to make the report easier to interpret, several aids, such as tables, charts, and diagrams, have been included. It is important to use effective language and present it in an organized manner in order to successfully combine the different components of the report.

Overview of types of research design

The manner in which research inquiry is carried out and the degree to which problems are formulated may be used as the foundation for a general classification of research designs. Researchers are required to use any sort of research design that is appropriate given the objective of the study, the nature of the variables being studied, knowledge of the research topic, and the availability of information.

There are two primary categories that may be used to broadly categorize research designs.

1. The design of exploratory research
2. The design of conclusive research

The research design is considered by some specialists to be:

1. the exploratory research design
2. A convincing plan for the research

a. Research layout that is descriptive

b. The design of a causal research study or an experimental research study

1. The Exploratory Research Design is the Most Fundamental Investigation Design It is the most fundamental research design since it is the means through which appropriate extra information about the research are gathered. The design acts as a compass to guide the subsequent research process.

2. Conclusive research design — The researcher will use conclusive research if the goal of the investigation is to reach any conclusion about the research topic. The primary purpose of using this research strategy is to establish a causal link or to test a hypothesis in order to arrive at a conclusion. Either a descriptive or a causal design may be used. It is important to highlight that a descriptive research design is used when the objective of the study is to provide a description of the studied phenomenon. ➔ If the goal of the conclusive study is to investigate the link between causes and effects, then the researcher would choose for the causal research design, which is also commonly referred to as the experimental design.

a. Descriptive Research Design: This is the stage at which the researcher attempts to describe the search phenomenon and is more explicit and clear about the research topic. It mostly employs quantitative data. A more systematic, formal, and well defined approach is used in descriptive design. When opposed to an exploratory design, it sets a certain result and has a more narrowed focus.

b. Causal research design — A researcher would employ a causal design when they wish to investigate the cause-and-effect connection between different variables. The researcher is interested not only in establishing a link, but also in examining the degree of the association, measuring it, and attempting to explain the variety in the results. It is more structured, stiff, and less flexible than before. Some industry professionals refer to the methodology of causal research as experimental research design.

Aspects to be considered before selecting research design

Before settling on a specific research design, researchers should do a thorough analysis of the study scenario. This will ensure that the research design chosen is appropriate and offers the most advantageous alternative course of action at each step of the research. Before settling on a particular design, it is important to give some thought to the elements listed below.

1. Knowledge of the research issue: The researcher's level of familiarity with the study topic, as well as the amount of material that is at his or her disposal, is a guiding element in choosing a design. When there is insufficient information about the study topic and the need for more investigation, an exploratory design is appropriate. On the other hand, if a researcher already has all of the knowledge that is essential about the study topic, then he might use the descriptive design.

2. Clarity of goals: Descriptive design is appropriate if the research objectives are known, clear, and there is no need to rework on the objectives of the research. In this case, there is no need to rework on the objectives of the research. The exploratory design is the one that should be used when there is a lack of clarity on the research goals, as well as when further deskwork or preparatory research is necessary to establish the objectives.

3. Hypothesis: If the research hypotheses are well established and presented without any ambiguity, then the researcher is free to choose either a causal or descriptive design, depending on the needs of the investigation. An exploratory design is appropriate when the aims of the study are unclear and it is necessary to define the hypothesis.

4. The requirement for Accuracy: If the researcher is interested in achieving a high degree of accuracy in their study, then it is recommended that they use either descriptive or causal research methods. Exploratory design, despite the fact that it gives accuracy, is based more on qualitative aspects, and it is not possible to obtain a high degree of precision.

5. The nature of the variable and the type of variable: Knowledge about the research variable, nature of the variable, and type of variable also plays a role in the decision-making process regarding

research design. Exploratory design is appropriate when the variables being studied are qualitative and when it is difficult to quantify them. If the researcher is familiar with the characteristics of the study variables and their relationships, and if the characteristics of the study variables are quantitative in nature, then a descriptive or causal design is acceptable. In addition to the aforementioned considerations, the choice of study design is also affected by the amount of time and money required to carry out the research, the level of risk involved, and other variables.

RESEARCH DESIGN FOR DESCRIPTIVE RESEARCH

Research studies that are considered to be descriptive are those that focus on characterizing the features of a specific person or of a group. In such studies, the design has to be stiff and not flexible, and it needs to concentrate attention on the following:

1. Establishing the purpose of the research (what the investigation will focus on, and why will it be carried out) The first thing that has to be done in order to make sure that the information gathered for a descriptive research is meaningful is to make sure that the goals are specified with appropriate accuracy.

2. Planning the procedures for the collection of data - (which strategies for amassing data will be utilized?) - This step is followed by the decision-making process of choosing the procedures via which the data are to be gathered. It is necessary to develop methods for the collection of the information. The researcher has access to a variety of methodologies, including observation, questionnaires, interviews, and the review of records, amongst others, and may choose to use one or more of these approaches in their investigation. During the process of creating the processes for collecting data, suitable precautions against bias and dependability must be provided.

3. Choosing the specimen - (how much of the material will be required?) The majority of descriptive studies include the researcher collecting samples from the population under study, who then intends to draw conclusions about the population based on the findings of the sample. It is important to approach the challenge of sample design in such a way that it is possible for the samples to provide correct

information while requiring a minimal amount of work from the researcher.

4. The process of data collection (where can the necessary data be located, and to what time period should the data be related?)

5. Putting the data through processing and analyzing- It is necessary to put the data that was obtained through processing and analyzing. This involves activities such as tabulating the data, doing several statistical calculations, and coding the interview responses, observations, and other relevant information.

6. Reporting the results- This job involves conveying the findings to others, and the researcher is responsible for doing so in an effective way. The structure of the report has to be carefully designed in advance in order to ensure that all aspects relevant to the research study may be presented in an organized manner that is clear and concise.

RESEARCH DESIGN FOR ANALYTICAL RESEARCH

Research that employs analytical processes and methods is known as analytical study. This kind of research focuses on quantitative data. It is possible that it will consist of a set of mathematical models or statistical approaches that may be applied to numerical data. Therefore, another name for it is the statistical method. The purpose of the analytical investigation is to put hypotheses to the test as well as to identify and understand connections. It places an emphasis on doing in-depth data analysis and investigating correlations from a variety of perspectives by include as many relevant variables as is practically practicable in the analysis plan. This strategy has widespread use in the corporate world as well as other areas where quantitative numerical data is created. It is used for determining the values of variables, contrasting different groups, and investigating the associations between different elements. Data may be gathered from either primary or secondary sources. Either one is acceptable. Analytical studies are distinguished by stringent standards for measurement and analysis, and their designs are often intended to be approximations of the experimental designs of other types of research.

RESEARCH DESIGN FOR EMPIRICAL RESEARCH

Empirical research is limited to using either experience or observation as its primary sources of data. Database research that arrives to results that can be validated by observation or experiment is an example of this kind of study. Research of this kind might also be referred to as experimental research. When conducting this kind of investigation, it is essential to collect first-hand data directly from the relevant institutions, as well as to take active steps toward producing the material that is being sought for. When doing this kind of study, the researcher is required to first come up with a working hypothesis or a best estimate on the likely outcomes. After that, he sets out to collect enough evidence (data) to either support or refute his theory. After that, he devises experimental designs that he believes will influence the individuals or the materials that are of interest in order to elicit the information that he is looking for. In this kind of research, the experimenter retains control over the variables that are being investigated, and he or she purposefully alters one of the variables in order to investigate the impact of the change.

RESEARCH DESIGN FOR EXPERIMENTAL RESEARCH

The experimental research designs serve as blueprints for carrying out the tests in a manner that is consistent with a certain framework. The following is a list of the main categories of experimental designs:

- Pre experimental design
- True experimental design
- Statistical design

1. Pre experimental design-Pre-experimental designs are frequently referred to as informal designs. Manipulation is another word for this.

2. Randomization The term "randomization" refers to the process of assigning participants to a treatment in an experiment in a way that is completely at random.

3. Control: In the context of performing an experiment, a control is a component that does not undergo any changes and is not influenced in any way by the other variables.

The two primary types of genuine experimental designs are the

1) Pre-test control groups and the

2) Post-test with control group designs.

1. In the Pre-test control groups, test units are distributed randomly to both the experimental and test groups at the same time. Only the members of the experimental group get therapy, and the dependent variable is evaluated both before and after it has been administered. The dependent variable is evaluated both before and after the experiment for the control group, but they do not receive any treatment.

2. Post-test solely with control groups (after just with the group serving as a control) - In this design, a preliminary test is not carried out. In this stage of the study process, the researcher will choose two groups at random to serve as the experimental group and the control group. After therapy has been administered to the experimental group, the dependent variable is assessed for the first time. The simultaneously dependent variable for the control group that did not receive treatment is assessed.

Qualities of a good research design:

1. A solid research design should be focused on the research topic and aligned with the study goals.
2. There can be no hint of partiality.
3. It has to be flexible enough to accommodate change and practical.
4. The criteria of validity, reliability, correctness, adequacy, economy, and efficiency should guide its development.
5. It need to be based on scientific principles, so that judgments on options at each step may be rationally defended.
6. It ought to strive toward a method that is both cost-effective and does not compromise the quality of the study.
7. It need to take into consideration the time frame in which the investigation is to be finished.
8. It should guide the methods for the gathering of data and the analysis of data.

Delimiting a Problem

All the elements required to answer the research question must be clearly addressed as part of the delimitation of the research topic.

The researcher should provide more details regarding the topic of the study than just the title while performing the study. The subject should be sufficiently narrow to make the research process easier. The researcher must provide a subject, a problem with a solution, a question with a reason, a general aim, the particular objectives, and the research's constraints. A delimitation is necessary to structure the whole procedure. The goal of defining the research topic is to determine the precise population to be investigated, the amount of time required to study the population, and the physical location where the research will be conducted.

The research question has to include reference of the three aforementioned components. It is crucial to note that certain issues do not need the three delimitation factors and will not have an impact on the inquiry.It should be emphasized that the problem's definition and the investigation's restrictions do not relate to the same thing. It often causes confusion for many individuals.

How should the research issue be defined?

Other factors, such as those listed above, should be taken into account after choosing the subject you intend to research. However, the three factors important to the definition of the research issue will be the main emphasis of this section.

In contrast to the title and goals, which must adhere to predetermined rules, there is no rule that specifies how to phrase the delimitations of the research topic. Making a specified subject the study object is the sole need for this component of the investigation.

It's crucial to remember that the researcher must justify his decision to explore the delimitations he selected as well as the reasons he didn't choose any other ones. The delimitations listed below are those that a researcher must take into account.

Geographical encirclement

The geographical or spatial delimitation entails confining the subject's examination to a certain location, whether it a particular

nation, state, city, or parish. This will enable the population to be examined to be deduced.

Population limit definition

The population to be used as the research's subject must be chosen once the study area has been identified. You may describe the population's age and gender in this section, as well as the total number of participants, or you can identify the institution or business that will handle the population function by name.

However, it may be further circumscribed if you wish to examine the population of an organization or business, designating the precise segment of the population to be investigated. A particular degree and area might be chosen, for instance, if you are an educational institution in addition to specifying the name of the institution. By doing so, it would openly and concurrently describe the geographical delimitation.

Timing restrictions

The length of time required to do the study will be determined depending on the topic. Given that this might be about events or phenomena that have previously occurred or are now occurring, it is crucial to be aware of the topic of study's scope.

Continuing with the example of population delimitation, if the researcher's population of choice is an educational institution, then the researcher needs to specify whether the study will be based on an entire elective year and which year it will be based on, or whether it will only be based on a given period of time.

Why is it being done?

Regardless of the topic being investigated, an inquiry has the potential to include significant points and societies as objects of study. The establishment of delimitations will assist in keeping the study at the centre of attention.

In order for the researcher to concentrate on the most important facets of the investigation, the delimitations are drafted so that they may serve as a kind of guide for him or her to follow. In a similar vein,

delimitations act as a map to direct readers in the direction of the sort of study that they will read.

Why even bother?

It is possible to have the misconception that the answers to the queries "what" and "why" will be the same; nevertheless, this is not the case. The question that has to be answered is "why is the delimitation of the research issue made?" is inextricably bound up with the question of why. On the other hand, they are not comparable.

The question "what for?" responds to the definite emphasis that the study will have, as was described earlier in the sentence. On the other hand, the delimitation is established, which is why it is necessary for you to establish a centre point. To put it in another way, to erect impassable barriers from which the investigator will be unable to escape.

These barriers are meant to, in a way, restrict the object of study that is being conducted. If there were no such obstacles, the amount of data that could be collected would be so enormous that the conclusion could not be written. It is necessary to begin by providing definitions of both the delimitations and the constraints of the research topic before we can proceed to determining the distinction between the two.

As was just discussed, the delimitations are used to determine the boundaries of the area that will be the focus of the research. This is done in order to provide a starting point and a conclusion for the gathering of data, and as a result, to acquire a topic that may be explored with more specificity. On the other hand, the constraints of the research might be seen as the study's flaws. These are all the aspects of the inquiry over which the researcher has no influence or over which it is impossible to make accurate predictions before they take place.

Nevertheless, the investigator has the ability to exploit the constraints that are readily apparent to their advantage. The researcher will be able to devise a strategy to address them once they have this information.

However, if these constraints do not permit the progress of research, then it is time for the researcher to shift the emphasis of the

study. Before beginning the process of research, these should be taken into consideration. Therefore, it is possible to assert that the most significant distinction between delimitations and limits is that the former are within the control of the researcher, but the latter are outside of the researcher's ability to exercise control.

Evaluation Research

What exactly is evaluations research ?

Evaluation study is a frequent kind of research design that comprises carrying out a systematic assessment of the worth of resources devoted to a project or specified aim. This type of research is often referred to as programme evaluation. It often makes use of several approaches from the field of social research in order to collect and examine relevant data about organisational procedures and outputs.

Evaluation research, which falls under the category of applied research, is often related with real-life situations that take place inside organisational environments. This indicates that in order to arrive at objective research results that will be beneficial to stakeholders, the researcher will need to harness standard workplace qualities such as interpersonal skills and the ability to play well on a team.

Research on Evaluation: Traits and Characteristics

1) Environment of Research: Evaluation research is carried out in the "real world," or more specifically, inside the framework of an organization.

   The primary aim of research in the field of evaluation is not the study of the process itself but rather the measurement of the results produced by the process.

   The findings of study have shown that evaluation research is used by businesses for the purpose of making strategic decisions.

2) Aim of the Research: The purpose of a programme evaluation is to establish whether or not a certain method has produced the anticipated outcome (s). The results of this kind of study serve to safeguard the interests of the organization's many stakeholders. It often occupies a position bridging the gap between fundamental and applied research. Research on evaluation is conducted in a

manner that is both comprehensive and ongoing. Rather to focusing on descriptions, it concentrates on the operations that are being performed. Process of Study This research design makes use of both qualitative and quantitative research approaches in order to collect pertinent data on a product or action-based plan. Among these approaches are observations, experiments, and questionnaires.

Different Kinds of Research on Evaluations

From "appreciative inquiry" to "connoisseurship" to "transformative assessment," the forty-two various evaluation techniques and models are covered in detail in Mathison's (2004) Encyclopedia of Evaluation. The following are examples of common sorts of research that are evaluated:

Evaluation in a Formative Sense

Before beginning a project, it is common practise to do a formative assessment, also known as a baseline survey. This kind of research entails determining the requirements of the users or the target market. Evaluation research always begins with formative evaluation since this sort of assessment establishes the overall tone of the organization's project and gives valuable information that can be used in subsequent forms of evaluation.

Evaluation at the Halfway Point

Assessing how far a project has progressed and judging whether or not it is in accordance with the goals and objectives that were established are both components of a mid-term review. Midterm reviews serve two purposes: they enable the company to assess whether or not a change or modification of the implementation strategy is required, and they act as a tracking mechanism for the project.

Summative Evaluation

This kind of assessment is carried out immediately after a project has been brought to a successful conclusion, and it is also known as an end-term evaluation or project-completion evaluation. In this stage of

the research process, the researcher analyses the value and outputs of the programme in relation to the outcomes that were anticipated. The organization is able to determine the level of success that a project achieved by conducting a summative assessment. These kinds of findings may be communicated to various stakeholders, target audiences, and potential investors.

Outcome Evaluation

Due to the fact that it assesses how a project, programme, or product impacts its end users, outcome assessment focuses largely on the intended recipients of the information. This sort of assessment examines the results of the project from the perspective of the audience that was intended to benefit from it. Changes such as greater work efficiency, improved knowledge, and acquired skills are often measured during this type of evaluation.

The Appreciative Inquiry Approach

An method to assessment study known as appreciative inquiry focuses on strategies that are effective in creating results. It is premised on the assumption that an organisation will develop in whichever direction its stakeholders give main attention to, so that if all of the attention were focused on issues, it would be simple to discover them. This view underpins the concept of stakeholder engagement.

When conducting appreciative inquiry, the research identifies the factors directly responsible for the positive results realized in the course of a project, analyses the reasons for these results, and then intensifies the utilization of these factors. Appreciative inquiry is a form of action research that focuses on finding and analyzing patterns of success.

Methodologies of Research and Evaluation

There are four primary approaches to research in the field of evaluation: the output measurement, the input measurement, the effect evaluation, and the service quality evaluation.

The measurement of output and performance

Evaluation study often makes use of a technique known as output measurement, which is designed to demonstrate the outcomes of an endeavour carried out by an organization. To put it another way, performance assessment takes into consideration the outcomes that were brought about by the application of resources to a certain endeavour or organizational procedure.

It is not enough for an organization to spend resources in a project; they must also be able to monitor the amount to which these resources have given outcomes. Performance assessment is where this tracking and tracking ability comes in. With the help of output measurement, businesses are able to focus their attention not only on the process itself, but also on how successful it is and what kind of impact it has.

User happiness, organizational capacity, market penetration, and facility usage are some more important factors that are considered while evaluating a company's success. Organizations need to determine the characteristics that are pertinent to the process at hand, as well as the industry in which they operate and the target markets, before they can conduct out performance assessment.

Variables in terms of their operationalization

When presenting a topic, a researcher has to make certain that it is neither presented in words that are so broad as to render it incomprehensible nor detailed in a manner that is so restricted as to render it meaningless and inconsequential.

In this way, the most important step is to explain the elements that are involved in the problem and characterize them in terms of the significance that they have in terms of their context. To illustrate this point, let's say that you made an announcement that you want to conduct research on the "Impact of Television on the Success of Learners in Course One of the Master of Arts in Distance Education that is offered by the Indira Gandhi National Open University." As an illustration, let's say that the Indira Gandhi National Open University is located in India. This is a fairly general phrase that explains in a very fundamental way what it is that you want to achieve in the future.

Having said that, it is necessary to characterize the problem with an exceptionally high level of specificity.

In order to do this, the first thing that needs to be done is to describe the variables that are a part of the issue and define them in terms of their operational meaning.

The terms "efficacy" and "performance" are the ones that are up for grabs in this predicament. It is important to keep in mind that the meanings of these idioms extend beyond those given in dictionaries. For instance, "creating the intended impact" is one of the definitions of "effectiveness" included in dictionaries. The interpretation presented here is insufficient for the purposes of study. It is essential that you be specific about the indicator of effectiveness that you want to use or the activities that you intend to do in order to quantify the existence or absence of the phenomena that is signified by the word "effectiveness." In a similar manner, you need to define the second variable, which is "performance," also in terms of the actions or procedures that will be used to quantify it later on. You can decide that for the sake of this research, "efficacy" refers to the degree to which Diploma students improved their results on a standardized achievement exam that was administered during Course One. It's possible that when we talk about "performance," we're referring to how well we did on the accomplishment exam for Course One.

The issue should be described in such a manner that it demonstrates a link between at least two of the variables. This is an important point to keep in mind. It should not entail any philosophical concerns, value questions, or questions of judgement that can't be resolved by scientific research.

Is it possible, for instance, that pupils' performance levels may be improved by increasing their exposure to television?

Research cannot provide answers to concerns of this kind about worth. In a similar vein, the question "what is there in television education that increase performances" is a philosophical subject that cannot be investigated in a straightforward manner.

Examination and Analysis of the Issue

Before beginning the investigation, it would be beneficial for you to pose a number of questions to yourself. The questions ought to be useful in evaluating the situation on several criteria, which will be discussed later. Before beginning the study, yes has to be given as a response to each and every one of these questions.

Which questions are the most important for us to ask?

i) Is the issue amenable to investigation?

There are certain issues that can't be resolved satisfactorily by the use of research for any reason. Always, the connection that exists between two or more variables that can be identified and quantified is the primary focus of an issue that may be investigated via research. It should be possible to describe the issue in the form of viable research questions that are capable of being addressed experimentally.

ii) Is this a recent occurrence?

There is no use in doing more research into a topic that has already been thoroughly examined by a number of previous scholars. It is vital to evaluate the literature that is accessible in the subject in question very thoroughly in order to prevent duplication of efforts like these. The issue at hand shouldn't be chosen until after you have shown without a reasonable doubt that it is, in fact, an uncharted territory that has never been thoroughly researched and solved. However, it is essential to keep in mind that a researcher is permitted to relaunch a study if he or she intends to validate the study's results or to eventually expand the authenticity of the study's findings in a framework that is vastly different from the one in which the study was initially conducted. This is something that a researcher can do in order to validate or extend the validity of the study's findings.

iii) Is the nature of the issue important?

The challenge should be designed in such a way that it has a good chance of filling in the blanks in the existing body of knowledge, of shedding light on some of the inconsistencies that were found in the earlier research, or of providing assistance in the presentation of the

evidence that are already known. This may be accomplished in a few different ways. The findings or outcomes of an investigation should serve as the foundation for either a theory, broad generalizations, or guiding principles. In addition, they should either give rise to new questions that may be investigated further or have some practical applications that might be of service.

iv) Is it possible for the specific researcher to tackle the problem?

It is possible for a research topic to be researchable, substantial, or innovative; nonetheless, it may still not be viable due to the following considerations:

a. Competencies in research: The issue at hand should pertain to a field in which the researcher has the necessary expertise and qualifications. It is vital for him or her to have the abilities, skills, and knowledge that may be required in order to design and manage the instruments for data collection, as well as evaluate the data that is accessible for analysis. The researcher should also possess the necessary understanding of the research design, qualitative and quantitative methodologies of data analysis, and other such skills that may be required in order to carry out the study all the way through to its conclusion. In addition, the researcher should possess the required understanding of research design, qualitative and quantitative methodologies of data analysis, and other such skills.

b. Interest and zeal: The researcher need to have an authentic interest in, and a healthy amount of zeal for, the subject that he or she plans to investigate in the course of the study.

c. Financial concerns and the problem's feasibility: The issue should be viable from a financial standpoint. It is the responsibility of the researcher to determine whether or not they have the financial and/or time resources required to carry out the study. Every project has some kind of expense associated with it, and this is especially true for DE initiatives that need students to be located in different locations. When considering feasibility, cost is an essential component. It is essential to determine the potential costs of the project as well as the financial resources that are available. Depending on the answer to this

question, it will become clear whether or not the project can be carried out.

d. Administrative considerations: In addition to personal limitations, financial limitations, and time constraints, the researcher needs to take into account the type of data, equipment, specialized personnel, and administrative facilities that are required in order to successfully complete the study. It is important for him/her to determine whether or not they will be able to get the assistance of a variety of administrative agencies in order to gather a variety of data kinds.

e. Time: The successful completion of a project is a competition against the passage of time. The great majority of you, if not most of you, are already engaged in more than one activity at the same time, whether it be at your place of employment, in your personal life, or within your social circles. It is essential to make an accurate estimate of the amount of time necessary to finish a research. In addition to the evaluation of the whole time, it is vital to determine which season of the year is most relevant to the investigation based on its purpose. For example, if you want to research the instructional transactions that take place during personal contact programmes, you will need to schedule your project in such a way that it allows you to really watch a number of sessions that take place during personal contact programmes.

UNIT 4
STATISTICAL TECHNIQUES AND TOOLS

Data collection is the systematic acquisition of information, such as observations or measurements. Collecting data allows you to gain first-hand facts as well as unique insights into the topic you are researching. This is true regardless of whether you are doing research for academic, governmental, or commercial purposes.

Although the methods and objectives of data collection may differ from field to field, the data collection process itself is, for the most part, similar. Before you begin data collection, there are a few considerations you must make:

The objective of the inquiry is to:

- The information categories that will be collected.
- The methods and activities you will use to collect, store, and analyse the data.

Follow these four steps to collect data that is of good quality and relevant to your intended use.

1) You must first establish the aim of your studies.

Before you can begin the process of data collection, you must have a crystal-clear understanding of what you want to achieve. You may begin by developing a problem statement that answers the following questions: what is the practical or scientific issue you intend to tackle, and why is it significant?

Create one or more research questions that precisely identify the information you want to get as the last stage. It is conceivable that you may need to collect quantitative or qualitative data to answer your research questions:

Quantitative information is often given in the form of numbers and graphs and is analysed using statistical methods.

Words are employed to represent qualitative data, which is subsequently analysed and classified for statistical analytic purposes.

If you want to test a hypothesis, gain an exact measurement of anything, or get large-scale statistical insights, you need collect quantitative data. Collecting qualitative data is advantageous if your goals are to test theories, interpret occurrences, or get a better understanding of a certain situation. If you have several objectives to achieve, you may choose a mixed-methods technique that collects both types of data.

Numerous instances of qualitative and quantitative research objectives

- You are doing research on how direct supervisors are seen by their direct subordinates inside a large organisation.
- Your major purpose is to determine if there are substantial differences in the opinions of managers from diverse divisions and office locations.
- Your second purpose is to obtain meaningful feedback from employees in order to examine fresh methods for enhancing managers' effectiveness.
- You conclude that a mixed-methods approach is the optimal technique for collecting quantitative and qualitative data.

2) Select the method through which you will collect data.

Determine the most suitable technique for your inquiry depending on the information you want to collect.

In experimental research, the application of quantitative methods predominates.

Among the qualitative research methods are interviews, focus groups, and ethnographies.

Archival research, questionnaires, observations, and secondary data collecting may all be classified as either quantitative or qualitative.

Consider carefully the strategy you will use to obtain the data that will get you closer to answering the research questions.

1) Plan out the procedures for data collection.

2) When you have decided the technique or approaches you will use, the following step is to explain how you will implement

these ideas. How will you guarantee that the observations or measurements you make of the variables of interest using the procedures you've created are accurate?

For example, if you are conducting surveys or interviews, you must choose the structure of the questions. If you want to perform an experiment, you must determine how the experiment will be constructed.

Operationalization

There are times when variables can be evaluated directly. If you ask employees for their dates of birth, for instance, you can simply determine the average age of your staff. On the other side, you will often be interested in acquiring knowledge on more abstract concepts or intangible aspects.

Operationalization is the process of converting abstract intellectual notions into observable and measurable facts. Converting the conceptual definition of what you want to investigate into the operational description of what you will measure is a critical step in defining how you will collect data.

Sampling

It may be necessary to develop a sampling strategy in order to gather data in a systematic way. Determining a population, or the broader group from which you aim to draw conclusions, and a sample, or the smaller group from which you will collect data, are both required phases in this procedure.

Your sampling technique will have a significant impact on how you recruit participants or collect data for your project. When selecting a sampling strategy, you will need to examine a number of different parameters, such as the intended sample size, the accessibility of the sample, and the length of the data collection.

Standardizing procedures

If several researchers are working on your project, you should create a detailed guide to standardize data collection procedures.

To guarantee that each member of your research team gathers data in a uniform way, you will need to provide them with comprehensive, step-by-step instructions. This may be achieved, for example, by running tests under identical settings and using objective criteria to record and classify findings.

This not only helps to ensure the integrity of your data, but you can also use it to recreate the whole study in the future.

Developing a data management plan

Before beginning the process of data collection, you should also have a strategy for storing and organizing the data you gather.

If you are going to gather data from people, you will almost likely need to anonymize and secure the data so that no sensitive information becomes public (e.g. names or identity numbers).

If you are collecting data through interviews or other techniques involving the use of pencil and paper, you will need to undertake transcriptions or data entry in a thorough way in order to minimize the possibility of distortion.

Having an organizational structure that regularly makes backups is one technique to prevent the loss of data.

4) Acquire the Required Information

At this stage, you are finally able to use the approaches you have chosen in order to measure or observe the variables of interest.

Following are some best practices that should be followed to ensure that high-quality data are collected in a systematic manner

Ensure that you record any essential information as soon as you have it. Consider, for example, if laboratory equipment is recalibrated throughout experimental study.

Check the manually entered data for errors twice.

If you collect quantitative data, you will be able to assess its reliability and validity, giving you a sense of the quality of your data.

What precisely does "Data Collection" mean?

Data collection is a thorough process including the collecting and evaluation of specific data in order to offer answers to applicable

questions and evaluate the consequences. It emphasises learning all there is to know about a certain topic or subject area. The objective of data collection is to test a hypothesis in an attempt to explain a phenomenon in the future.

The testing of a hypothesis eliminates the need for assumptions while simultaneously creating a claim supported by logic.

There are several objectives for which data collectors acquire information, each with its own possible outcomes. The primary purpose of data collecting, on the other hand, is to enable the researcher to predict future possibilities and trends with more accuracy.

Primary and secondary data are the two most prevalent types of information that humans may obtain. The first kind of information is collected by a researcher from first-hand sources, whereas the second type is collected by a non-user third party.

The Various Data Collection Methods

Before delving into the intricacies of the various data collection methods, let's first create some context. It is essential to remember that the process of data collecting may be divided into two distinct categories: primary data collection and secondary data collection.

The acquisition of primary data

Primary data collection is the acquisition of unprocessed data at the source. This is what primary data collecting entails. It is the process of assembling the main data collected by a researcher for a specific research project. It may be further subdivided into quantitative data collection techniques and qualitative research approaches.

Research Method Based on Qualitative Data

The qualitative research approaches of data collection do not require the collection of numerical data or the need to infer via the use of mathematical calculations; rather, it is based on qualitative characteristics such as the researcher's experience or emotion. Such an approach may, for instance, consist of an open-ended questionnaire.

Method of Measurement

Quantitative techniques include the use of numbers and need a mathematical derivation of the findings for comprehension. In order to get data that can be calculated statistically, it is possible to conduct research using a questionnaire with solely closed-ended questions. In addition, correlation and regression approaches, as well as the mean, mode, and median.

Information Obtained from Secondary Sources

On the other hand, secondary data collection refers to the gathering of data from sources other than the original user. This kind of data collecting is known as second-hand data acquisition. Data mining is the process of collecting data that already exists, whether in the form of previously published books, journals, or online portals. It is also far less expensive and easier to collect than other methods.

The nature, scope, and location of your research, as well as its aims and objectives, should inform your judgement about whether primary or secondary data collection is more suitable.

The relevance of data accumulation

There are several reasons at play, especially for a researcher in terms of data collection. Explaining them in detail, the following are some of the reasons why:

Investigate Integrity and Objectivity

One of the most significant reasons for collecting data, whether qualitative or quantitative, is to ensure that the integrity of the research topic is maintained.

Reduce the likelihood of making errors.

When appropriate data collection processes are used, the likelihood of errors that are consistent with the results is decreased.

Making a Call or Selection

It is crucial to collect trustworthy data so that the researcher does not make conclusions without enough knowledge in order to reduce the possibility of decision-making errors.

Spend both less money and time.

The researcher may save time and money by gathering data that would ordinarily be required but would be squandered without a deeper understanding of the topic or issue.

To meet a need for a novel idea, a novel approach, or cutting-edge innovation, it is necessary to develop a novel concept, a novel approach, or cutting-edge innovation.

It is crucial to collect data as evidence to support these statements in order to prove that a change in the norm or the introduction of new information that will be accepted by the majority of people is necessary.

What precisely is a data collection tool?

The phrase "data gathering tools" refers to the many devices and equipment used for data collection. Computer-assisted interviewing systems and paper questionnaires are examples of data collecting instruments. Case Studies, Checklists, Interviews, and, on occasion, Observation, as well as Surveys and Questionnaires, are examples of data collection techniques.

Due to the fact that research may be conducted in a number of ways and for a range of purposes, it is necessary to choose the data collection equipment. The objective of data collection is to collect credible evidence for the purpose of performing an analysis, which will then result in the formulation of credible and convincing answers to the addressed issues.

The seven most successful methodologies and devices for data collection in academic, opinion, or product research are listed below.

The seven most successful methods for gathering data for academic, opinion-based, or product research are listed below. The nature of each, as well as its advantages and disadvantages, are also examined in detail. This section will provide you with the most up-to-date information available on the approach best suitable for your research.

INTERVIEW

An interview is a face-to-face conversation between two persons whose main aim is to collect relevant data for a research purpose. The

interview may take place in person, through telephone, or via video conference. There are many various interview types, with organised, semi-structured, and unstructured dialogues being the most prevalent. Each of these forms is distinct from the others in some way.

Utilize this template for an interview consent form to allow an interviewee to provide you permission to utilize interview data for the purposes of conducting an investigational research.

Structured Interviews are, in their most basic form, a spoken questionnaire administered to the respondent. In terms of depth, it is often completed quickly and does not go behind the surface. It is strongly suggested if you place a premium on quickness and effectiveness, but it lacks depth and intricacy.

In the case of semi-structured interviews, there are a few key questions designed to cover the breadth of the topic under investigation. This provides the researcher with a little more freedom to examine the subject matter.

Unstructured Interviews are a kind of in-depth interview that allows the researcher to acquire information on a wide range of subjects while remaining focused on the research issue. This strategy offers a lot of advantages, one of which is that it allows researchers to combine structure and flexibility in their work, despite the fact that it requires much more time.

Pros

Specific information and facts
Freedom and flexibility in practise
Accurate data.

Cons

Time-consuming
Gathering is a pricey endeavour.

What are the most effective data gathering tools while doing interviews?

Using interviews, you may collect data in a simple and effective way by using the following techniques:

Sound Recording Equipment A device that can record sound onto a disc, tape, or film is known as an audio recorder. Audio information has the ability to meet the needs of a varied range of persons and may act as an alternative to conventional data collection techniques.

Digital Camera

One of the advantages of a digital camera is that it allows the user to transmit captured images to a display screen anytime this capability is necessary.

Camcorder

Frequently, a camcorder is used while conducting interviews for data collecting. It combines a video camera and an audio recorder into a single, user-friendly gadget. The material provided is qualitative in nature, and respondents were given the option to reply to all of the questions posed. If you need to record sensitive material during an interview but also need to protect your subject's privacy, a camcorder may not be the most appropriate instrument to employ.

Do you need to collect qualitative information or create a specific report and want to conduct an interview? Before utilising interview data for research or a report, you must first get the interviewee's permission using our online interview consent form template. Formplus Builder is the most effective tool for building online permission forms, even if you lack coding knowledge. Among other premium features, it includes electronic signatures, upload fields, and form security.

QUESTIONNAIRES

A data collecting instrument is a series of questions and prompts provided to someone in order to elicit a response. This procedure is known as data collecting. The objective of questionnaires is to collect information from group members.

It is crucial to clarify that a questionnaire is not the same as a survey; rather, it is a part of the latter. A questionnaire is only one of

the several data collection methods that may be used during a survey, which is a process that gathers data using a variety of methods.

A questionnaire normally consists of three separate types of questions. They are known as open-ended, scale, and fixed-alternative questions. With each inquiry adapted to the kind and scope of the investigation being done.

Pros

Can be distributed to a large number of individuals at an acceptable cost.
This study may be compared and contrasted with previous studies to measure change.
Easy to imagine and comprehend.
Questionnaires deliver actionable data.
The respondent's name will remain confidential.
Utilizing questionnaires permits comprehensive coverage of a topic.
Costs a reasonable amount overall.

Cons

It is likely that respondents will not provide truthful responses because they become bored halfway through the poll.
Questionnaires can't produce qualitative data.
It is conceivable that certain inquiries will not be answered.
There is a chance that responders have anything to conceal.
Not all issues are amenable to easy analysis.

Paper Questionnaire

A paper questionnaire is a data collection tool consisting of a sequence of questions and/or prompts designed to elicit responses from respondents. This data may then be put into a database. Despite the fact that their major purpose is statistical analysis of the findings, they may also be used to gather data.

REPORTING

Data reporting refers to the process of gathering and submitting information for further inquiry. Since faulty data reporting may lead to

misinformed decision making, reliable data reporting is the most crucial aspect of data reporting.

Pros
Decision-making that is based on information.

Cons
Self-reported replies are not guaranteed to be accurate.
There is a chance that bias affected the results.
It is likely that responders are too ashamed to disclose all of the requested data.
Inaccurate reports will lead to ill-informed decisions.

Which Data Collection Instruments Are the Most Effective for Report Generation?

Reporting tools enable you to extract data and display it in the form of charts, tables, and other visualizations so that users may discover relevant information. You could get the information you need for your report from non-governmental organization (NGO) reports, newspapers, online articles, or medical records.

The Reports of Non-Governmental Organizations

The reports provided by non-governmental organisations (NGOs) provide an in-depth and detailed account of the organization's activity, addressing themes such as business and human rights. The content of these articles relates especially to research and may serve as a suitable academic basis for the collecting of data. NGOs focus their efforts on coordinated development projects that advance a certain cause.

Newspapers Not only are newspaper statistics relatively easy to collect, but they are also sometimes the only continuously available source of event information. Even though there is a problem with bias in the data released in newspapers, it remains an effective tool for gathering information for reporting.

Content Discovered on Websites

Reading Internet articles in order to extract and utilise the information offered there is another type of data collection. The collection of information from web publications is a more efficient and less expensive way. There may be inherent biases in the data collection process, and there may be concerns regarding the confidentiality and security of the data obtained using this method. These are two of the most major disadvantages of using this technique of data reporting.

Hospital Care records

In the health care business, several governmental and commercial data gathering methods are deployed. Health surveys, administrative enrollment and billing information, and medical records are included in these systems. Numerous institutions, including hospitals, CHCs, doctors, and health insurance, employ these systems. The offered material is succinct, impartial, and accurate; nonetheless, it must have been obtained via legal routes, since medical information is subject to the strictest rules.

EXISTING DATA

During this stage, new investigative questions are offered in lieu of or in addition to the questions posed during the first phase of data collecting. It involves combining measurement into a research or inquiry. This is illustrated by retrieving data from a repository.

Pros

The degree of precision is rather high.
Information that is easily accessible.

Cons

Evaluation concerns must be addressed.
Understanding is not simple to gain.

Which Data Collection Tools Are the Most Efficient for Existing Data?

The phrase "existing data" refers to the process of acquiring information from pre-existing sources in order to address research

questions that are distinct from those for which the data were originally collected. Among the available tools for acquiring existing data are:

Unlike newspapers and magazines, which are published for a wide public, research journals are produced for a particular academic or technical audience. A journal is a scientific publication that contains articles written by researchers, academics, and other informed persons.

Surveys are a type of data collection involving the collection of information from a subset of a community in order to extrapolate the results to a larger population. Surveys may be used for a variety of purposes, and their implementation can take a variety of forms, depending on the desired outcomes.

OBSERVATION

Observation is a kind of data collection that includes acquiring information about a phenomenological event via direct experience. The nature of the observation might be conducted in one of four ways: as a complete observer, an observer who also participates in the activity, a participant who also observes it, or a participant who fulfils both roles. This method provides a crucial basis for the creation of a hypothesis.

Pros

Easy to use and administer.
It is possible to get a better degree of accuracy with the results.
It is an internationally recognized standard.
It addresses the issue of respondents' reluctance to submit a report by overcoming their resistance.
There are instances when it is permissible to do so.

Cons

Certain events are not visible in their normal condition.
It cannot be relied upon in any manner.
Bias may arise.
It incurs a substantial expense to handle.
It is impossible to forecast its truthfulness with precision.

Which observational data gathering methods are the most efficient?

Observation refers to the process of actively acquiring knowledge from first-hand sources. Using different sorts of scientific equipment to collect data and record observations is another type of observation. The following are the most effective observational tools:

The use of checklists, which are state-specific criteria, enables users to access information and make decisions on what they should know in relation to the outcomes. They give a systematic approach to the collecting of data on certain behaviours, knowledge, and skills.

Direct observation, a method for gathering evaluative data, is under the field of observational research and studies. The evaluator examines the subject in his or her normal environment without altering that environment.

FOCUS GROUPS

This method of data collecting stresses qualitative research more than quantitative research, which is defined by the collection of numerical data. It is considered the primary kind of information for data based on the feelings and perceptions of respondents. This research comprises asking open-ended questions to a group of people, often between six and 10 individuals, in order to collect feedback.

Pros

In most instances, the gathered information is highly precise.

This strategy leads in substantial cost reductions as compared with individual interviews.

It is a reflection of the efficiency and speed with which results are delivered.

Cons

Insufficient depth in addressing the core issues of a subject.

The risk of prejudice remains.

Interviewer certification is necessary.

The researcher has relatively little control over the ultimate outcome.

A small number of strong voices may quickly overwhelm the others.

Challenges inherent in establishing an inclusive group.

What are the most efficient data collection methods for focus groups?

A focus group is an approach for gathering data in which members are carefully observed and the conversation is structured according to a set of predefined questions. The purpose of the meeting is to learn as much as possible about how the participants would respond to the questions. The following are the most successful focus group tools:

One group watches the responses of the other group to the questions posed by the moderator. After hearing what the other group has to say, the attentive group is in a better position to encourage more discussion and may reach different conclusions than the first group.

In the "dueling-moderator" style, two moderators take turns playing the role of "devil's advocate." The primary benefit of using duelling moderators for a focus group is that it facilitates the generation of new ideas by exposing members to new ways of thinking and diverse perspectives.

COMBINATION RESEARCH

This strategy for acquiring information employs creative methods to stimulate more participation from individuals and groups. In addition to relying on focus groups and interviews to collect qualitative data, this strategy also includes interviews. This technique is crucial when dealing with sensitive subjects.

Pros

Encourage responses from participants.

It enables people to develop stronger bonds with one another.

The respondents' ability to maintain a level of anonymity increases their participation.

Consequently, the received information is of greater quality.

Cons

It is the most costly of the top seven alternatives.

It is the most time-consuming option.

What are the most efficient methods for data collection while doing combination research?

Combination Research is a methodology that combines two or more data collection techniques, such as interviews in addition to questionnaires or semi-structured telephone interviews and focus groups. Examples of such techniques include: The following are the most effective research techniques for combination studies:

Internet-based interviews and the completion of questionnaires are the two modalities that comprise the online survey. There is an internet-based questionnaire that may be completed by the target population. It is fast, efficient, and effective simultaneously. Especially given the quantitative nature of the required data collection.

The two approaches that comprise this dual-moderation strategy are focus group conversations and structured surveys. While two moderators supervise the proceedings, structured questioners give direction for the direction of the research. While one person ensures that the session with the focus group runs well, the other ensures that all of the questions requested are answered. Almost often, focus groups with two moderators result in a more productive session, which increases the quantity of information collected from the experience.

Here Are Seven Tips to Help You Create the Most Effective Surveys for Data Collection:

Specify the objective of your survey. Once the aim of your survey has been determined, it will be simpler to determine which questions should be prioritized. For instance, if there is a clear explanation for why something is happening, there should also be a clear goal that can be achieved. Example: "The goal of this survey is to have a deeper understanding of why workers are leaving an organization."

Employ questions that are not open-ended but rather explicitly expressed. You should avoid open-ended questions and avoid guiding the respondent towards the answer you believe they should provide. If feasible, provide a range of replies along with choice alternatives and star ratings.

The survey findings should have a favourable and promising outlook. A more visually beautiful survey will encourage more individuals to participate and offer comments.

Assure Respondents of the Security of Their Data Because you want your respondents to feel comfortable providing you with their personal information, it is crucial that you reassure them that their data will be safe. It is your obligation to advise respondents that the information they provide will be kept strictly confidential and used only for research reasons.

Ensure that your survey can be completed in record speed; ideally, users should be able to complete a normal survey in less than one hundred seconds. It is essential to remember that responders are providing you with a favour by offering feedback. They should not be subjected to excessive pressure. Keep your comments brief and direct to the point.

Conduct a test survey and examine a preview of it before distributing it to the individuals who are expected to respond. Create a test version and email it to a few persons for their input. On the basis of the replies to your survey, you will be able to make conclusions and determine whether or not it is ready for prime time.

Include a prize in the survey to give users something to look forward to when the survey is completed. Give your respondents something to anticipate upon completion of the survey. Imagine it as a cent for every pound of flesh they sacrificed throughout their battle. This may provide the motivation they need to complete the survey instead of quitting up halfway through.

An Explanation of the Sampling Method in Detail

It is critical that we carefully consider each individual before inviting them to take part in our research and become a member of our sample group. The way in which we choose our participants will determine the size of the population to which our results may be applied, and this will rely on the approach that we adopt (random sampling).

INTRODUCTION TO THE TERMS "POPULATION" AND "SAMPLE" IN RESEARCH

The term "sample" refers to a smaller representative of a larger group or aggregate that has been selected from among all of the individuals that make up that larger group. To phrase it another way, the sample provides a representation that is indicative of the total as a whole.

This more all-encompassing entity is referred to as "the people" and "the universe" in common parlance. This expression is used in a broader sense in the field of study; it refers to a well-defined group that may include humans, items, human qualities, or even the behaviour of insentient things, such as the roll of a dice or the flip of a coin. Additionally, it may refer to a well-defined group that may include humans, items, human qualities, or even the behaviour of insentient things. The behaviour in question may be seen by rolling a dice or flipping a coin, for example.

It is not possible to conduct research that involves each individual member of a population and arrive at a conclusion that can be trusted based on the evidence gathered from that group since doing so would be impractical. In addition, the numbers of populations are often so large that the study of all the units would not only be expensive, but it would also be challenging, time-consuming, and tiresome. This is because it would be necessary to do the research in a very meticulous manner. For example, IGNOU's undergraduate programme now has more than fifty thousand students registered in it. For the aim of our research, it is impossible for us to acquire information on the studying habits of all of these students.

Because of this, in order for a researcher to carry out the survey, they will need to choose a sample from the whole population that is representative of the whole. The process in issue is known as sampling, and its name describes what it does.

It is crucial that the sample correctly represents the characteristics of the population as a whole if we are going to make inferences about the features of the population based on a sample. These conclusions will be based on the sample. In addition to this, it necessitates the selection of a "representative proportion" of the whole

population. In the population, it's conceivable that there are only a set number of persons or units. There are certain contexts in which it is appropriate to speak to the population as "infinite," such as when discussing the varying degrees of atmospheric pressure that may be found in various parts of the atmosphere. Because of this, it is essential to establish a detailed description of a population so that there is no room for ambiguity about the question of whether or not a certain unit is a part of the population. This will ensure that there is no room for confusion. In this case, the researcher would be at a loss to decide which units need to be taken into account when picking a sample since there is no clear pattern to follow. For instance, one of our goals is to reach a degree of knowledge about the methods of education that are used by students who are enrolled in programmes that are offered via distance learning. It is hard to establish who the population is since we are not given any information on which university or universities need to be included in this poll. It is difficult to tell who the population is in this situation since the population is not stated in the proper way. When everything is said and done, there are over nine distinct methods for choosing from among the one hundred educational institutions in India that provide remote learning, not to include the thirteen open universities that are run by the government. As a direct result of this, in order to provide an appropriate description of it, we need to define the group as, for example, students who are enrolled in the undergraduate programme offered by the IGNOU.

The second factor that goes into determining the degree to which a sample is archetypical of the whole population is the determination of the "sampling frame," which is the listing of all the units of the population under distinct headings. This is done so that the sample can be more accurately representative of the whole population. In the study that was just presented, there is the possibility for a wide range of sample frames, which may include male and female students, employed and unemployed students, and students from other backgrounds as well. Before selecting a sample, the sampling frame has to be established, at which time it need to already be exhaustive, accurate, and current.

Thirdly, the examination of a sample need to be conducted in a manner that is unbiased and impartial. It ought should offer all the information there is to know about the people from whom it was taken, if we lived in a perfect world, and it should. According to the induction principle, which indicates that one should go from the particular to the general, this sort of sample would be deemed to be within the margin of error for random sampling. This is because the induction principle implies that one should travel from the specific to the general. This gets us to the results, which are next discussed in terms of "probability."

A sample should not only be accurate in portraying the population as a whole, but it should also be large enough to ensure that its features remain consistent. It is necessary to fulfil both of these prerequisites. Then, what precisely is the most appropriate measurement for the size of a sample? A sufficient sample is one that includes sufficient numbers of instances to assure that the results may be believed. In other words, a sufficient sample is one that meets the criteria for "sufficient." If the characteristics of the population being researched are fairly constant, then a small representative sample will suffice. On the other hand, in order to have an accurate representation of the population as a whole, it is necessary to have a sample size that is far larger than is typical. Therefore, the process for determining the sample size differs based on the sort of characteristics that are being investigated as well as the distribution of those qualities throughout the population. This is because the sample size is used to represent the whole population. In addition, the appropriateness of a sample will be determined not only by the method that was used to generate the sample, but also by our understanding of the population from which the sample was drawn. This is because the sample will only be representative of the population from which it was drawn. For example, if we try to find out the study habits of undergraduate students at Lady Irwin College in Delhi, the population will obviously be more similar to one another than the population of undergraduate students at IGNOU in terms of socio-economic status, employment of students, or study hours available. This is because the population of undergraduate students at Lady Irwin College in Delhi is much smaller than the population of undergraduate students at IGNOU. This is due to the fact

that IGNOU has a more diversified community of students enrolled in its undergraduate programmes. However, it is vital to be aware that even if the sample is of appropriate size, this does not necessarily ensure that the results will be correct. This is something that has to be taken into consideration.

METHODS OF SAMPLING

When attempting to arrive at credible results or conclusions, one of the most crucial considerations to take into account is the method that was used to choose the sample that was used in the study. This topic was brought up in the most recent segment of this conversation. In light of this fact, we are going to move on to a discussion of the various methods of sampling that are accessible in this section here. When it comes to a rough classification, the many different sampling techniques may be broken down into the following two categories:

i) Probability Sampling
ii) Non-probability Sampling

Probability Sampling

When employing probability sampling, the selection of units to sample from a population is done so in a way that is completely random. To put it another way, the researcher does not have any influence over the selection of units to sample; rather, the procedure is carried out in such a way that each unit in the population has an equal chance of being included in the final results. This is because the procedure is carried out in such a manner as to ensure that each unit in the population has an equal chance of being sampled. In the case of something like a lottery, for example, every single individual has the same chance of being selected. The following are some of the properties of a probability sample:

I the selection of units to be included in the sample is made in one or more steps of the sampling procedure that is automated;

ii) the analysis of the sample uses weights that are appropriate in light of the probabilities; and
iii) each individual in the population has a certain chance of being included in the sample that is taken.

The process of conducting probability sampling may be carried out in a number of different ways, and each of these ways has a distinct collection of benefits and drawbacks that are exclusive to that method. An overview of these subjects is provided in the following abbreviated form:

A simple or unrestricted method of sampling is preferred for random sampling.

An example of simple random sampling would be the selection of a sample from a finite population via the use of a procedure in which every unit in the population has an equal chance of being picked [see to item I above]; this would be an example of selecting a sample from a population. In point of fact, you may easily produce a random sample by going through the following steps in the following order:

i) Please provide an explanation of what you mean by "population."
ii) Make a list of all of the units that comprise the population, and number each unit starting with one and going up to n.
iii) Determine the size of the sample, also known as the number of units that will be included in the sample. iv) Compute the standard deviation of the sample.
iv) Choose the units that are going to be included in the sample by either making use of the "lottery approach" or the "random number tables."

For instance, if there are n units in the population, you could use the lottery method to choose a sample at random by making use of a set of n tickets, each of which would have a number from 1 to n printed on it. The numbers on the tickets would be in ascending order, starting with 1 and going all the way up to n. After giving the tickets a thorough shake, the sample of the needed size is selected by selecting the required number of tickets from the shuffled stack. For this example,

let's suppose that the required size is x. It will be determined that the units that have serial numbers that are printed on these tickets are the ones that have been chosen. The success of this tactic is reliant on the assumption that the tickets are jumbled together in such a manner that the population may be seen as being grouped in a way that is completely at random. Before selecting one hundred people at random from the whole population of one hundred thousand undergraduate students at IGNOU, you would write the roll numbers of all of the students on little pieces of paper in a similar fashion.

First, the chits should be mixed together, and then the roll numbers for the five hundred should be chosen.

When drawing a sample from a simple random pool, the most efficient method is to use a table containing random integers as the generator.

These tables, which include random numbers, have been created and are available. The same goes for Yates and Fisher (1967). After having first allotted consecutive numbers to the different units of population, the researcher then moves on to the next step of reading consecutive numbers from the table of random numbers, which may begin at any place. The researcher has the option of reading the successive numbers in whatever orientation they want, including horizontally, vertically, or diagonally. If the number that is read out agrees with the number that is displayed on one of the unit cards, then that unit will be used as the sample. If the numbers do not coincide, then the sample will not be taken from that unit.

The approach known as systematic sampling technique

Through the use of systematic sampling, one is able to produce a distribution of the sample that is more uniform throughout the population list, which eventually results in improved accuracy. The following steps are included as part of the process:

I Create a list of the population units based on some kind of order, such as alphabetical, seniority, street number, house number, or any other similar criteria that you believe to be acceptable.

ii) Figure out the proper sample percentage, such as fifty percent out of one thousand, as well as the number of the Kth unit. For example: [K=N/n= 1000/50 = 20].

iii) Choose one thing from the list for every Kth unit, starting with a number chosen at random between 1 and K, and making sure to include both numbers in the range. In the preceding example, if the number that was chosen at random was 4, the sample would include the fourth, twenty-fourth, forty-fourth, sixty-fourth, and eighty-fourth units of each series that went all the way up to the nine hundred and eighty-fourth unit.

This strategy results in a sample that is on par with that of a plain random sample, and it is a great deal less difficult to put into action. A researcher who is interested in studying the average telephone bill of an area in his or her city could select every fourth telephone holder at random from the telephone directory and find out what their annual telephone bills are. This would allow the researcher to study the average telephone bill of the area. This would make it possible for the researcher to investigate the typical monthly telephone bill of a certain neighbourhood in his or her city. The structure of the population units is not randomised, which is one of the reasons why this method has several drawbacks, which are outlined in more detail below.

i) Periodic effects

It is not at all unusual to come across populations that have a periodic tendency that might be more or less distinct. A few examples of periodic trends or cyclic fluctuations in a given population include the number of students present at a residential university library that is open seven days a week, sales at a store over the course of twelve months in a year, and the flow of road traffic past a particular traffic point on a road over the course of twenty-four hours. All of these examples take place over the course of one year. Under these types of conditions, a systematic sample may not precisely represent the population or might not be beneficial all the time. Alternatively, it could not be useful at all.

ii) Trend

One further drawback of systematic sampling is that very often, "n" is not an essential multiple of "k," which is a factor that has to be taken into account. This is a problem that needs to be taken into consideration. As a consequence of this, the sample will include an unpredictable number of units that are drawn from the same restricted population. Take into consideration the following possibility: A researcher is interested in selecting 20 of the most experienced counsellors from a pool of 100 who are ranked according to the number of years they have been practicing. To begin, the person determines the size of the gap by taking the number that is generated by dividing 100 by 20, which is 5, and using that value. Let's imagine that he or she picks the number 4 at random from the range of 1 to 5 for the first number in the sequence. After that, he or she selects a name every fifth time beginning at 9 and continuing through 14, 19, and so on until he or she has drawn the required number of names, which is 20. If this individual uses the number 2 as their starting point, then another illustration would use the digits 2,7,12,.... Each counsellor's seniority in the second sample is lower than the seniority of his or her counterpart in the first sample. This is because the first sample contains more experienced counsellors. The mean and average of these two samples would be significantly different from one another if we were to compare them based on seniority and the other factors that are associated with it. When starting from a number of different locations, one may be able to gather a large number of samples in this manner; but, there will be greater variation among them.

Calculations that are carried out using samples of this kind are unable to provide insight into the factors that contribute to variability because the 'periodic effects' and 'trend' of the population in question contribute disproportionately to the increase in the samples' overall degree of variation.

The most important advantages of utilizing a technique of systematic sampling are as follows:

a) The calculations are less complicated, and

b) It has a lower overall cost compared to other methods, such as random sampling.

Stratified random sampling is a kind of sampling method.

There are a few different scenarios in which the population that requires a sample cannot be assumed to be uniform. As a consequence of this, rather of selecting people from the overall population at random, the main population is divided into a number of sub-populations that are referred to collectively as strata. One or more of these features are shared by each of these strata, making them all comparable to one another (s). After that, a method known as random selection is used to pick certain aspects of the sample from inside each stratum. Therefore, the sample is representative of each and every strata in its entirety. Because the population is first stratified into its sub-populations before the selection is performed, this method of sampling is referred to as stratified random sampling. This is due to the fact that the condition of random selection is satisfied by the selection that is made inside the strata.

The process of stratified sampling consists of the phases that are outlined in the following list:

I Determining the appropriate stratification characteristics, which may include gender, age, geographical location, the kind of education acquired, and a variety of other factors as well.

ii) The procedure of subdividing the whole population into smaller groups by utilising the stratification criteria as a map to direct the process.

iii) Providing specific information on the individual units that are included in the listing for each distinct subpopulation.

iv) Using a suitable random selection technique to pick the needed number of units from each sub-population in order to finish the selection process. v) Using the units that were chosen in step iv.

v) Combining the samples from the subsamples into a single, bigger sample that will serve as the principal one.

Because of this, the degree to which a sample is representative of the population as a whole may be improved via the use of stratification, which contributes an additional component to the control process. On the other hand, the efficiency of the stratified random sample is dependent on the distribution of the sample size over all of the strata. This is because the strata are divided up into subgroups. There are three

unique ways of allocation that may be used within the context of stratified random sampling, which are as follows:

1. Equal Allocation

When taking a sample of this kind, each stratum provides the same number of items to the total collection as the other strata. As a result, if there are three distinct strata, one third of the sample will be selected from each of the distinct strata. This form of allocation is carried out when there is a balance of population between the strata that are being considered.

2. Proportional Allocation

In this kind of sample, the contribution that each stratum makes to the overall number of samples is proportional to the size of that stratum's share of the population as a whole. When a stratum is larger, it is able to contribute a higher number of people to the sample because of this fact. The level of the sample fraction is held steady at the same value.

3. The Distribution That Is the Most Effective

In optimal allocation, the contributions of each stratum to the sample are calculated in such a way that they are proportionate to the artefact of the strata population sizes and the amount of variation in the dependent variable that exists within each stratum. This ensures that the sample is representative of the population as a whole. The strata that are either larger in size or have a higher degree of variability will provide a greater proportion of the total to the sample. Because precise calculations of the population variability of the dependent variable are seldom available before the sample is selected, the optimal allocation is rarely applied. This is because the optimum allocation needs exact predictions of the population variability of the dependent variable. Because of this need, precise estimates of the amount of variation that exists within the population of the dependent variable are almost never accessible.

When there are no easily available lists of the units or people who make up the population, it is useful to use a stratified random sample because it provides more accurate results. In addition to this, it is useful since the conclusions that it gives are more accurate than those that can be obtained from only random sampling. For instance, in the process of selecting a sample of undergraduate students from the Open University in your country, the researcher may decide that the entire population of undergraduate students should be broken down into males and females, north, east, south, and west regions of the country, and should then be employed in government, private, and autonomous institutions in the country. This decision may be made while the researcher is in the process of selecting a sample of undergraduate students from the Open University in your country. All of them will be their own individual layers or strata. The researchers may choose a sample size ranging from 50 to 15 children from each demographic category. There are several circumstances in which stratification is not possible before the data are gathered.

It's likely that the researcher won't be able to tell to which stratum a unit belongs until after they've finished the survey and analysed the results. Personal characteristics, such as age, gender, social standing, educational level, and so on and so forth, are all examples of such elements that may be used to stratify populations. In situations such as this one, the method includes first acquiring a random sample of the required size, and then secondly classifying the units into a number of distinct strata once the sample has been categorised. The method is highly efficient provided that the sample is large enough, that is, provided that there are more than 20 people in each stratum.

Cluster-based methods for collecting samples

Cluster sampling is utilized in situations in which the population that is being studied is infinite, there is no list of units of population, the geographic distribution of units is dispersed, or when sampling of individual units would be inconvenient for a number of different administrative reasons. It involves segmenting the population into groups or clusters with the purpose of using those groups as the

primary sample units for the data. Following that, a decision is made on which of the clusters are going to be included in the sample. As a result, the sample unit for cluster sampling is the cluster itself, as opposed to an individual member of the population or an item from the population as a whole.

For the purpose of selecting a sample of middle school teachers in a state, for example, you could enlist all middle schools rather than teachers teaching in middle schools and then randomly select ten percent of the middle schools as clusters. Another option would be to select all teachers teaching in middle schools. You would then be able to pick certain middle school teachers as candidates for the sample. After then, the persons who make up the sample might be selected at random from among the educators working at the selected schools, or the sample can be made up of any and all of the educators working at those schools.

A "cluster" may be described as any geographical location in which we find a continuous group of individuals who have characteristics that are similar to one another (members of a population). There are many other kinds of settings that have the potential to be categorized as clusters, including classrooms, schools, hospitals, and study centres. Cluster sampling is an efficient method to utilize, especially in circumstances in which the cost of measuring a unit is comparatively cheap in relation to the cost of travelling to it.

Multi-stage sampling

In order to conduct research with more depth, it is common practise for large-scale surveys to employ many phases of sampling. It's feasible that the researcher may need to take samples in two, three, or even four separate phases.

For the purpose of gathering information from respondents located in various parts of the country, for example, postal questionnaires are often used as the main technique of data collection. It is conceivable for incomplete questionnaires to establish a bias, which would make it difficult to obtain a sample that is representative. This is true despite the fact that the technique is cost-effective. In order to remove this bias, it is necessary to use a sampling method that

consists of two stages. A second sample is gathered from the individuals who did not respond. This sample is selected at random by personal contact with the individuals. By carrying out this action, the dependability of the data obtained from the first sample may be removed from the list of items that need to be validated. In a similar vein, if a researcher is interested in conducting a survey of counsellors located around the nation, he or she may pick a sample consisting of five states, each of which may represent a distinct region: the north, the south, the west, and the centre of the country. A comprehensive database of all of the districts in these five states may be prepared, and then a random sample of thirty to forty districts can be chosen from among them. It is possible to build, using this information, an inventory of all of the study centres that are situated in the different districts. After then, a random selection is made to provide a representative sample of somewhere between 300 and 400 distinct research centres. In addition, counsellors who volunteer to take part in the research are chosen at random from a pool of between 1500 and 2000 individuals. It is also possible to produce a multi-stage sample by randomly picking first the state governments, then the district governments, then the study centres, and finally the individual counsellors. Because of the use of multi-stage sampling, the burden that is imposed on respondents is lessened, expenses are kept to a minimum, time is saved, and an accurate representation of the sub-sample is produced more rapidly and successfully. On the other hand, one should only think about using this strategy if it seems to be difficult to choose a simple random sample.

The correlation between the sample size and the likelihood of an event.
Methods for the Collection of Samples
The Resources That Are At Your Disposal For Research

When the units vary in size, it is desirable to choose a sample in such a way that the probability of selection of units is related to its size. This is the best way to ensure that there is a balanced distribution of results. When attempting to achieve a true and accurate depiction of the people, this is of the utmost importance. One learning centre has a total population of two hundred pupils, whereas another only has one hundred students enrolled. This is only one example. When it comes

time to choose a sample, the first research centre will have access to double the number of individuals that the second research centre will have available to them.

This particular kind of sample is referred to as a PPS sample, which is an acronym that stands for probability proportion to size sample.

Implementation of Computers Into the Procedure of Sample Selection

There are a lot of websites that you may visit, each one of which will provide you with random numbers for your own personal usage.

To provide one example, the website www.randomizer.org may be navigated and used in a very straightforward manner. You will be required to submit answers to a variety of questions the first time you use this website. These questions include the following: how many sets of random numbers are to be formed; how many numbers are to be produced for each set; number range; and so on.

A broad number of software programmes are equipped with the capability to pick samples at random from their respective databases. One example of this sort of software is the Statistical Program for Social Sciences (SPSS) for Windows 15.0 (SPSS, Inc., 2006), which was developed by SPSS. SPSS provides users with two distinct choices when it comes to determining the size of the random sample to be taken:

a. To an exact degree; b. Approximately As its name suggests, precisely calls for an exact or specific quantity, such as 600 out of 2000 Class IX students being indicated. The second option, on the other hand, gives the user the freedom to choose the sampling fraction, which is also sometimes referred to as the ratio of sample size to population size. For instance, one may select thirty percent of all of the students who are now enrolled in Class IX.

There is a wealth of software available on the market today that, in addition to a simple random sample, enables the selection of a random sample based on a more intricate set of criteria than is possible with a plain random sample. You are allowed to use any programme so long as you adhere to the instructions that are outlined in the user manual that comes packaged with the software.

Non-probability Sampling

The term "non-probability sampling," which is also known as "non random sampling," refers to the sampling techniques that do not include any aspect of random sampling at any point in the selection process of the samples. Another name for this technique is "sampling without probability," which is a synonym for "non random sampling." The phrase "non probability sampling" is also used to refer to the same procedure since it is impossible to calculate the likelihood that each individual member of the population will be picked for the sample. This is why the word "probability sampling" is used. When selecting samples for this assignment, the researcher will do so according to his or her own judgement. The availability of the units, the personal experience of the researcher, and the simplicity with which the researcher may carry out a survey are the guiding components in non-probability sampling. Non-probability samples are the sort of samples that are referred to as "non-probability" samples because it is not possible to calculate the chance that any one particular member of the population will be selected for the sample. Depending on the approach that was used, nonprobability samples may be divided into one of three categories: incidental samples, quota samples, and deliberate samples. Each of these subcategories has its own unique set of characteristics. The following is an explanation, although a shortened one, of these various samples:

Incidental sample

The word "incidental sample" is used to refer to samples that have been obtained owing to the easy availability of units. It is also known as a "accidental sample" or a "convenient sample." Other names for this kind of sample are "convenient sample" or "accidental sample." The phrases "convenient sample" and "accidental sample" are concepts that are related. An investigator working for the IGNOU who is conducting a research project on the perceptions that distance students have regarding MDE has the option to conduct interviews with learners who are currently enrolled in the MDE programme and who happen to visit the university for one reason or another. This choice can be made during the course of the research project. These pupils can be reached

without much effort and fulfil all of the criteria that have been established for the study. Nevertheless, despite the fact that they have a predetermined population, there has not been any genuine randomization conducted. This is one of the problems with the research. As a consequence of this, any attempt to arrive at a generalised conclusion under the sorts of circumstances described above will result in wrong assumptions and interpretations. The key advantages of using this approach are the ease with which testing can be performed, the comprehensiveness of the data that is provided, and the convenience with which units can be obtained. Other benefits include the following:

Quota sample

A quota sample is a sort of non-probability sample that is used in the conduct of survey research more often than any other non-probability sample type. This kind of sample is used in situations in which it is physically impossible to list each and every member of the population of interest. It entails the selection of sample units within each stratum on the basis of the judgement of the researcher rather than on the basis of a calculable probability of the individual units being included in the sample. This is in contrast to the probabilistic sampling method, which selects sample units on the basis of the probability that they will be included in the sample. To be more specific, it entails selecting sample units in the way as follows: Imagine that there is a need to conduct a survey covering the whole nation using a quota sampling approach.

In order to carry out quota sampling, the first thing that has to be done is to split the population into several strata based on geographical characteristics such as rural vs urban regions, administrative districts, and so on. This will allow for a more accurate representation of the population. The next thing that has to be done is to figure out how many individuals will be selected from each category of the population. When it comes to the first phases of the sampling process, quota sampling operates in a way that is analogous to stratified sampling. On the other hand, in contrast to probability sampling, it does not always begin with a method for random selection from the beginning of the

process. This is due to the fact that it functions differently. The most basic difference between probability sampling and quota sampling is found in the methods' respective approaches to the selection of the final sample units. The majority of the time, the quota is determined by looking at the percentages of the different groups.

Imagine for a second that there is a researcher who is interested in investigating the viewpoints that university instructors have on the topic of distance learning. First of all, he or she may categorize the instructors at the establishment according to their gender, and then after that, he or she might further categorize them as professors, readers, and lecturers. It is possible that at some point in the future, he or she will make the decision to establish quotas for each of these groups. In this way, the quota sample would include the use of strata; but, selection within the strata would not be carried out in a manner that was entirely random. The information was gathered from the individuals who were easiest to contact and most readily accessible. Those individuals that are harder to communicate with therefore have a less proportion of their voices heard.

Using quota sampling provides a variety of advantages, some of which are that it is more practical, less expensive, and suited to scenarios in which there are missing or incomplete sample frames. Another advantage is that it is suitable for circumstances in which there are missing or incomplete sample frames.

Purposive sample

In certain circles, the term "judgement sample" is used interchangeably with "purposive sample." The reason why this specific form of sample was chosen to represent the whole population is because there are solid reasons for the opinion that it is representative of that group as a whole. The researcher will choose a sample for the study based on his or her prior experience dealing with the group that will be sampled. This will be done to ensure that the results of the study are accurate. For the purpose of conducting research on "gifted" children, for instance, the researcher would, on the basis of his or her prior experience, select particular individuals who have demonstrated exceptionally high levels of achievement in school while excluding all

other students from the sample. This would be done in order to ensure that the results of the study are accurate.

A purposive sample is different from a convenience sample in that, instead of choosing individuals based on their availability at the time of the study, the researcher draws on their previous expertise and experiences to establish the selection criteria for the sample. This is in contrast to a convenience sample, which chooses individuals based on their availability at the time of the study. When talking about purposive samples and arguing for the validity of such samples, the stated criteria serve as the basis that these conversations are based on. In qualitative research, the majority of the sampling is done on purpose. This is due to the fact that the primary emphasis is not placed on individuals who necessarily reflect some larger population, but rather on people who may give rich material for an in-depth study on the specific issue and setting. It is more critical that the participants be able to offer the information that is required than that the sample be as representative as possible.

Purposive sampling is a technique that may be used in qualitative research, and it encompasses around sixteen different kinds of specific approaches that can be utilized in qualitative research. The following are a few instances of such things: selection at random from a pool of candidates for a specific purpose One has the option of picking the required number of persons from among the subjects who were selected purposively when the size of the purposive sample is more than what they are able to work with. The technique in issue is called "random purposive sampling," and its name describes exactly what it does. For example, if the researcher had chosen twenty prospective participants for the study on purpose but could only interview 10 people, they would choose ten subjects at random from the pool of twenty potential participants.

The practice of selecting a limited number of persons who are then charged with discovering other individuals who they feel would make ideal participants for an inquiry is referred to as "snowball sampling." This practice is referred to by the phrase "snowball sampling." When conducting interviews with members of a population, for example, you may ask those being questioned to suggest other

people who might be able to be contacted for additional information or viewpoints about the topic at hand. You may also ask those being questioned to suggest other people who might be able to be contacted for additional information or viewpoints about the topic at hand. After that, you conduct interviews with these new individuals and continue in the same fashion until the information gets saturated, at which point you are unable to obtain any fresh viewpoints from the new persons you have interviewed. For example, a researcher wishes to analyse the opinions of distance learners on the quality of Swayam programmes, but they can only find five people who listen to these programmes. She asks these students if they have any other information that they can share with her.

They give her with a number of other references, and those references in turn create more links of their own. She is able to communicate with a sizeable number of people who are learning Swayam as a result of these ways.

When we do not have access to a sufficient number of people who have the characteristics we are looking for, such as in a situation when possible participants are scattered or not found in clusters, for such populations that are not well delimited nor well enumerated, for example the homeless, snowball sampling is the most useful method. Snowball sampling is also useful when we do not have access to a sufficient number of people who have the characteristics we are looking for.

The technique has the drawback of not providing an accurate image of the genuine distribution of viewpoints within the population that is being researched, which is a disadvantage. People have a tendency to propose people with whom they are acquainted and who share their values; as a consequence, communities of interest that cater to a certain niche are often ignored in favour of those that are bigger and more prominent. You might try asking people to nominate persons who have the same ideas as them as well as those who have the opposite viewpoint as them as a way to make up for this. This might be one option to rectify the imbalance in the situation. An alternate tactic is to start the snowball chain with not just one but many different

people, maybe coming from a range of different social groups. This is an example of an alternative use of the phrase "snowball effect."

Intensity sampling is the process of selecting cases that are rich in information, manifest the phenomenon intensely, and allow for the study of different levels of a research topic without selecting cases that are extreme or deviant. In other words, intensity sampling excludes selecting cases that are extreme or deviant. Examples of intensity sampling include distance tutors who have either extensive or limited experience, excellent or subpar students, students who score above or below the average, and experienced or inexperienced distance tutors. When doing intensity sampling, it is necessary to have both prior information and make an effort to explore the area in order to be able to uncover examples of high intensity. One of the many methods of sampling that may be used in conjunction with many other procedures is known as intensity sampling. For instance, one may collect fifty samples and then, for the purpose of conducting a more in-depth analysis, choose a smaller set of really severe situations.

The practice of selecting people who are considerably similar to one another in terms of their experiences, attitudes, or perspectives is referred to as homogenous sampling. This makes it more simpler to collect and analyze data, while also lowering the amount of variation that occurs. For instance, rather than focusing on enrolling as many students as possible in all of the many professional programmes that can be completed online, the school may decide to focus on only one programme at a time, such as the B.Ed. programme by itself. This allows the school to better cater to the needs of its students.

The use of stratified purposive sampling elucidates the characteristics of certain subgroups of interest and makes it simpler to compare the many different groupings.

In criteria sampling, a criterion is first set, and then all of the examples that satisfy that criterion or have some feature are picked. This process begins with the selection of the cases that have the criterion. For instance, all of the distance instructors with ten years of experience might be sampled, as well as all of the distant learners who fell out of the formal system but finished the programme via the distance mode of instruction. Both groups of individuals may be

surveyed. This particular method of sampling delivers the greatest possible standard of quality control and assurance.

Extreme and deviant case sampling is a method that involves learning from highly unusual manifestations of the subject of interest. Some examples of this method include learning from exceptional triumphs or substantial failures. Learning from previous situations' illustrative cases is the focus of this strategy.

When the sample size that needs to be picked is relatively small and the researcher wishes to gain an understanding of the features of the population in a short amount of time, non-probability samples are often regarded as being more convenient than probability samples. This is because non-probability samples can be selected at random, whereas probability samples require the researcher to select each member of the sample at random. In circumstances such as these, the primary objective of the researcher is to get insight into the problem at hand by selecting just those individuals who are capable of providing the greatest quantity of information on the problem.

The use of non-probability sampling methods is associated with the following list of inherent restrictions, which can be found in the following order:

i) There is not yet a statistical theory that has been developed to quantify the dependability of data obtained through purposeful or other non-random sampling methods. The reason for this is that it is not possible to select samples of this kind at random. Because of this, there is no reason to put any trust in the data that were acquired from such samples, and one cannot generalise the conclusions to the whole population as a result of their findings.

ii) The use of selective sampling based on convenience has an influence not only on the variation between groups but also on the variation within each group. This is because the convenience of the sampling method is taken into account. In addition, there is no statistical method that can be utilized to determine how much of a margin of error is associated with sampling.

iii) There are times when such samples are based on an obsolete frame that does not cover the population in a manner that is deemed acceptable.

The Process of Choosing Which Sampling Method to Employ

A lot of criteria that are unique to the current project being worked on are taken into consideration in order to make a decision on the method of sampling to use. These include concerns regarding the definition of population, the availability of information regarding the structure of the population, the parameters to be estimated, the objectives of the analysis including the required degree of precision, and the availability of financial and other resources. In addition, there are concerns regarding the availability of information regarding the structure of the population. In addition to this, there are issues with the parameters that need to be approximated. Because of this, selecting a sample for the operation of any kind of research study has to be done with extreme caution.

Those characteristics that make an outstanding illustration

It is important for a decent sample to have the characteristics of I Representativeness and (ii) Adequacy. The characteristics of a good sample are as outlined above.

It is very essential for the information gained from the sample to be "representative" of the population as a whole for it to be possible to generalise the findings of the sample to the whole population. The term "representative sample" refers to an ideal "miniature" or "replica" of the population from which it was selected. This "miniature" or "replica" may be thought of as an exact representation of the population. This is what is intended when the phrase is used. To put it another way, the average of the characteristics of the components that make up the sample is the same as or very near to the average of the qualities that make up the population. This is the case because the sample is representative of the population.

A good sample should also be "adequate," which means it should be of sufficient size to establish faith in the stability of the attributes it has. This is one of the criteria for determining whether or not a sample is adequate. When determining whether or not a sample satisfies the requirements for an acceptable one, one of the factors that is considered is whether or not it has a sufficient number of examples. Because of this, determining the size of the sample in advance is something that

has to be done as soon as possible. Both the nature of the traits that are being analysed and the manner in which they are distributed have an effect on the fluctuations that are seen. It is possible to point out that the findings will not necessarily be accurate even if the representativeness and adequateness of the sample are satisfactory. The techniques of data collection and sampling both need to be properly selected and implemented in order to attain a higher degree of accuracy in the conclusions drawn about the population and the generalizations that are drawn from those conclusions.

Certain study data are qualitative in character. Qualitative data include information on the attitudes, opinions, or behaviours of workers, customers, sales people, and others. In research conducted in the fields of psychology and sociology, the words "attitude" and "opinion" have often been distinguished from one another. The difference between an opinion and an attitude that is often made is that an opinion is a verbalization of an attitude, while an attitude is seen as a tendency to behave in a specific manner. As a result, the assertion made by a respondent that he favours watching television shows in colour as opposed to black-and-white would be considered an opinion that expresses one facet of the respondent's attitude toward colour television. Evaluation of attitudes is necessary for determining things like as motivation, commitment, level of satisfaction, and the efficacy of leadership, among other things. In order to accurately assess this qualitative data, measuring scales are required.

Different kinds of measurement scales that might be found in research

Research employs nominal, ordinal, interval, and ratio scales of measurement, each of which is a distinct kind of measuring system. The kind of scale and degree of measurement are both defined by the rules that are employed to assign numbers to things. The following provides a concise explanation of each scaling type:

The nominal scale is the most straightforward approach to the measuring of quantities. A variable that is assessed using a nominal scale is one that can be separated into two or more categories. For instance, gender may be classed as either male or female, and the response to the question of whether or not a family has an iPhone can

be either "yes" or "no." It is nothing more than a sorting procedure in which all of the persons, units, or responses may be put in either one of two groups (i.e. the categories are exhaustive). One of the most important aspects of a nominal scale is that each person is distinct from one another in terms of the variable being measured, and that the categories can be differentiated from one another (i.e. the categories are mutually exclusive). This aspect of categorization is essential to the operation of each and every scale of measurement. Nominal scales that only have two categories, such as female and male, agree and disagree, aware and oblivious, yes and no, are considered to be dichotomous scales and are considered to be unique. Due the numerical labels for the two scale categories may be considered as if they are of interval scale value, dichotomous nominal scales are relevant to researchers. This is because of the importance of interval scale value.

Ordinal Scales: Ordinal scales have all of the features that a nominal scale has, but in addition, categories may be ordered along a continuum, in terms of a particular criteria. Ordinal scales have all of the properties that nominal scales have. On an ordinal scale with three categories labelled A, B, and C, one could be able to argue, for instance, that A is greater than B, and one might also say that B is greater than C. If numerals are assigned to the categories of an ordinal scale, those numerals serve only as ranks for ordering observations from least to most in terms of the characteristic that was measured. They do not indicate the distance between scales that organise observations in terms of categories such as high, medium, and low or strongly agree, agree, not sure, disagree, and strongly disagree. If numerals are assigned to ordinal scale categories, those numerals serve only as ranks for ordering observations from least to most in terms of the characteristic that was measured

Interval Scales: Interval scales combine all of the qualities of nominal and ordinal scales, in addition to indicating the distance or interval between the categories. Interval scales are a hybrid of nominal and ordinal scales. Not only is it possible to assert in a formal sense that A is higher than B and that B is higher than C, but one can also state that (A-B)=(B-C) or that (A-C)=(A-B)+ (B-C). Age, income, and investment portfolios are all good examples of interval scales. On the

other hand, a scale is said to be interval if there is no absolute zero point. It may be located anywhere along a continuum; for example, a person's age can be anywhere from 20 to 60 years old; it does not necessarily have to begin at 0 years old. The ratio comparison, which states that A is twice that of B or such, is invalidated by this.

The ratio scale is a subtype of the interval scale that varies from other interval scales in that it features a real zero point, which is a point at which the quality being measured is assumed to be missing. This point distinguishes the ratio scale from other interval scales. Some examples of ratio scales include length, weight, income, and other expenses as well as other metrics. In each, the thought of having no income, weight, or anything else is present. As a general rule, ratio scales and interval scales are not differentiated from one another, and both names are used interchangeably. This is due to the fact that ratio scales are a more precise form of interval scales.

The four different kinds of scales that have been discussed so far each have their own particular way of measuring things. Nominal and ordinal scales have the characteristic of having a fixed number of distinct categories to which points are allotted. Therefore, the only possible values for a variable like the number of households who possess a BMW or iPhone are zero, one, two, three, and so on. Due to the fact that the units are integers and cannot be divided, it cannot have values such as 1.5 or 2.5. However, interval and ratio scales are able to accept any value between two integers since the variables in these scales are continuous. For instance, given any two ages, regardless of how close they are to one another, it is feasible to discover a third that falls somewhere in between. Interval and ratio scales are preferable than normal and ordinal scales, and their analysis may make use of a wide variety of statistical methods. Normal and ordinal scales are not as flexible as interval and ratio scales. The many statistical tools and measurement scales used in research are connected in the sense that there is typically a correlation between the mathematical assumptions behind each statistical instrument and the assumptions underlying each measurement scale. Always make sure that the instruments you're using correspond to the scale of measurement of the variables you're working

with, and make sure that the technique you're using indicates a greater scale measurement than the variable really permits.

Sources of error in measurement

Measurement Errors in the Scientific Research Methodology

In a perfect research study, the measurements of errors in measurement would be clear and unambiguous. This purpose, on the other hand, is not always accomplished in its full. As a result, the researcher has to have an understanding of the factors that contribute to measurement inaccuracy. The following are some of the potential factors that contribute to measurement errors.

Responder: Sometimes the respondent could be hesitant to voice strong negative sentiments, or it's conceivable that he might have very little information but might not accept his ignorance. It's also possible that he might have very little knowledge but might not admit his ignorance. Because of all of this hesitation, the interview will probably consist of a lot of "guesses." The capacity of the responder to react precisely and completely may be hindered by fleeting circumstances such as exhaustion, boredom, or worry, amongst others.

The characteristics that are present in the situation might also make it difficult to get accurate measurements. Any circumstance that makes the interview more difficult will likely have a negative impact on the relationship between the interviewer and the responder. For example, if there is another person there, that person may influence the replies either by taking part in the conversation or just by being there. It is possible that the responder may be hesitant to convey certain thoughts if he believes that his anonymity is not guaranteed.

The interviewer has the ability to skew replies by changing the phrasing of questions or switching their sequence. His demeanour, mannerisms, and appearance might either promote or discourage certain responses from responders. The results might have been skewed due to careless mechanical processing. Inaccurate coding, improper tabulation, and/or incorrect statistical computations are additional potential sources of error, especially during the stage of the process when data analysis is being performed.

Instrument: An inaccurate reading may be obtained due to a malfunction in the measuring instrument. A number of factors, including, but not limited to, the use of difficult words that are beyond the comprehension of the respondent, ambiguous meanings, poor printing, insufficient space for responses, response choice omissions, and so on, all contribute to the defective nature of the measuring instrument, which can lead to measurement errors. Another form of instrument flaw is one that results in an inadequate sample of the whole set of things that are of concern.

The researcher has to be aware that accurate measurement is contingent on properly resolving all of the issues that have been outlined above. In order to prevent the final findings from being tainted throughout any way, it is imperative that he makes every effort to eradicate, nullify, or otherwise deal with any and all potential errors in the process.

Measures of central Tendency and Measures of dispersion

What exactly is meant by "Central Tendency"?

A descriptive overview of a dataset that is represented by a single number that represents the centre of the data distribution is referred to as the central tendency. In descriptive statistics, the central tendency of a dataset is one of the subfields, along with the variability (dispersion) of the data.

One of the most fundamental and fundamentally important ideas in statistics is the central tendency. Even while it does not give information on the specific values that are included in the dataset, it does provide a complete overview of the dataset as a whole.

Calculations of the Mean and Variance

In most cases, the following metrics may be used to provide an accurate description of a dataset's central tendency:

A dataset's mean, also known as its average, is calculated by taking the sum of all the values in the dataset and dividing it by the total number of values.

The value that is in the centre of a collection of numbers that are ordered from lowest to highest (from the smallest value to the largest

value). When a dataset has an even number of values, the median of the dataset is determined by taking the mean of the two values that are in the centre of the dataset.

The mode of a dataset is defined by the value that appears the most often. Some datasets could have more than one mode, while others might not have any mode at all. This depends on the specifics of the dataset.

Even though the aforementioned measures are the ones that are used to identify central tendency the most often, there are a few others, such as the geometric mean, the harmonic mean, the midrange, and the geometric median. These are not the only measures available, however.

The characteristics of a dataset should be taken into consideration before deciding on a central tendency measure to use. For example, the sole central tendency measure that can be used with categorical data is called the mode, although the median is most useful when working with ordinal data.

In the case of quantitative data, the mean is often thought to be the most accurate indicator of the central tendency; however, this is not always the case. It's possible, for instance, that the mean won't function very well with quantitative datasets that include values that are either exceedingly high or extremely low. It's possible that the extreme numbers will skew the mean. As a result, you may think about taking further actions.

You may calculate the measures of central tendency by using a formula or looking up the definition. In addition, one may recognize them via the use of a frequency distribution graph. It is important to take note that the mean, the median, and the mode are all positioned in the same place on the graph when the data follows a normal distribution.

Suppose you are given a data series. Someone has asked you to discuss some fascinating information about this data series. How can you do so? You may state that you are able to tell about the distribution of these data by finding the mean, the median, or the mode of this data series. But is it the only option you have available to you? Is there no other method for us to learn about the focus of the observation except looking at the key tendencies? In this part, we will get further

knowledge about the data by becoming familiar with another measurement. The measure of dispersion is what we are going to learn about in this section.

What exactly is the dispersion?

The 'distribution' of things over a vast area is what we mean when we talk about dispersion. In statistics, the term "dispersion" refers to the extent to which numerical data are scattered or compressed around an average value. In other words, dispersion measures how close numerical data are to the average. The scattering of data is what it boils down to, in a nutshell. There will always be a large quantity of data that is either densely packed or widely scattered. Information with a large range of values, such as 0, 30, 60, 90, and 120. With little data clustered closely together as 1, 2, 2, 3, 3, 4,...

Understanding Dispersion

The degree to which a collection of data is scattered is referred to as its "dispersion." The dispersion measure is always a non-negative real number that begins at zero when all of the data is the same and climbs as the number of different data points increases. Dispersion metrics are what determine whether or not the dispersed data have a homogeneous or heterogeneous distribution. Additionally, it refers to the ways in which the data vary from one another.

Dispersion Quantification and Measures

The metric known as dispersion illustrates the scatterings that are present in the data, as its name indicates. It offers a clear picture about the distribution of the data and reveals how different the data are from one another in terms of variation. The measure of dispersion reveals whether or not the observations are distributed in a manner that is homogenous or heterogenous.

Imagine that you have four datasets of the same size, and that the mean of all of them is the same number—call let's it m. In any scenario, the total number of observations will amount to the same value. The measure of central tendency is not providing an accurate

and comprehensive picture of the distribution of the data for the four sets that have been provided.

If we learn about the distances that the observations have from one another both inside and across the datasets, is it possible that this will provide us some insight into the distribution? The primary goal of the dispersion measure is to provide insight into the manner in which the data are dispersed. It illustrates the degree to which the data deviate from their mean value.

Measures of dispersion have certain characteristics.
A rigorous definition has to be established for a dispersion measure.
It ought to be straightforward to compute and comprehend.
Not much influenced by the shifting patterns of observations
Given all that has been seen
Measures of Dispersion Are Divided Into Several Categories
The following kind of measurements make up the dispersion:
I An absolute measure of dispersion that takes into account:
The dispersion of the observations is expressed by the metrics in terms of distances, such as the range and the quartile deviation.
A measure that describes differences in terms of the average of deviations from observations, such as the mean deviation and the standard deviation, is called a measure.

(ii) A relative measurement of dispersion that takes into account:

When comparing the distributions of two or more data sets, as well as when doing unit-free comparisons, we look at the dispersion using a relative measure. The coefficient of range, the coefficient of mean deviation, the coefficient of quartile deviation, the coefficient of variation, and the coefficient of standard deviation are the names given to these statistical measures.

Different Types of Dispersion Measurements

The observations and varieties of central tendency measurements that are used both have a continuous influence on the dispersion. These are some examples of measures that may be used to disperse:

Range
Variation away from the middle point
The standard error of the mean
The standard error of the mean
Range

The term "range" refers to the disparity in value that exists between the lowest and highest points in each series. The range gives us a decent sense of how scattered the data is, but in order to determine the dispersion of data based on central tendency measurements, we need additional measures of variability. A range is the most frequent kind of dispersion measurement, and it is also the most straightforward to comprehend. It is the gap between the two most extreme observations in the data collection. If the maximum and minimum values of X are the two most extreme observations, then...

Range = X max – X min
The Value of the Range
It is the most straightforward method for determining dispersion.
It is simple to compute.
Simple and easy to grasp
Unaffected by a shift in the point of origin
Demerits of Range

It is based on two quite different kinds of observations. Therefore, allow yourself to be influenced by changes.
Dispersion cannot be accurately measured based on range alone.
Dependent on change of scale
Quartile Deviation

The quartiles split a data collection into quarters. The first quartile, abbreviated as Q1, is the number that falls exactly in the centre of the data set, between the lowest number and the median. The median of the data set is located in the second quartile, often known as Q2. The number that falls in the third quartile, also known as Q3, is the one that is in the halfway between the median and the highest number.

Quartile deviation or semi-inter-quartile deviation is
$Q = ½ \times (Q3 – Q1)$
Considerations Regarding the Quartile Deviation

All of the limitations of Range are addressed by its departure from the quartile.

It utilises 50% of the available info.
Unaffected by a shift in the point of origin

The most accurate representation of the open-end classification's dispersion

The Positive Aspects of the Quartile Deviation
It disregards fifty percent of the available data.
Depending on the degree of the shift in scale
A measure of dispersion that cannot be relied upon
Variation from the Mean

The arithmetic mean of the absolute departures of the observations from a measure of central tendency is what is meant by the term "mean deviation." If the set of observations is comprised of x1, x2,..., xn, then the mean deviation of x from the average A (mean, median, or mode) is calculated as

The standard deviation of the mean, A, is equal to 1 n I xi minus A].
It is computed as follows for a frequency that is grouped:
The mean value of the departure from the average A is equal to 1N I fi $|xi – A|]. , N = \sum fi$

Here, the median value of the ith class interval, denoted by xi, as well as its frequency, denoted by fi, are shown.

The Value of the Standard Deviation
Given all that has been seen
It provides a minimal value when the deviations from the median are taken into consideration.

Unaffected by a shift in the point of origin

The Positive Aspects of Standard Error

Not readily digestible by the average person

The computation of it is not simple and takes a lot of time.

Depending on the degree to which the scale is altered

Lack of understanding of the negative sign leads to the creation of artificiality and renders further mathematical treatment pointless.

The standard deviation of values

The positive square root of the arithmetic mean of the squares of the deviations of the provided values from their arithmetic mean is the formula for what statisticians refer to as a standard deviation. It is represented by the Greek letter sigma, which may be written as. A different name for this concept is root mean square deviation. The expression for the standard deviation is:

$$\sigma = [(\Sigma i\ (yi - \bar{y})/n]\ ½ = [(\Sigma\ I\ yi\ 2/n) - \bar{y}\ 2]\ ½$$

It may be shown that, with a clustered frequency distribution,

$$\sigma = [(\Sigma i\ fi\ (yi - \bar{y})/N]\ ½ = [(\Sigma i\ fi\ yi\ 2/n) - \bar{y}\ 2]\ ½$$

The variance is equal to the square root of the standard deviation. In addition to that, it is a measurement of dispersion.

$$\sigma\ 2 = [(\Sigma i\ (yi - \bar{y})\ /\ n]\ ½ = [(\Sigma i\ yi\ 2/n) - \bar{y}\ 2]$$

It may be shown that, with a clustered frequency distribution,

$$\sigma\ 2 = [(\Sigma i\ fi\ (yi - \bar{y})/N]\ ½ = [(\Sigma\ I\ fi\ xi\ 2/n) - \bar{y}\ 2].$$

If we choose any other random number, let's say A, as the new mean, the standard deviation will be transformed into the root mean deviation.

The Combined Series in its Variant Form

If 1 and 2 are two standard deviations, then n1 and n2 are the sizes of the two series, and 1 and 2 are the means of each series. The standard deviation of the two series of sizes, n1 and n2, is calculated as follows:

$\sigma 2 = (1/ n1 + n2) \div [n1 (\sigma 1\ 2 + d1\ 2) + n2 (\sigma 2\ 2 + d2\ 2)]$

where, $d1 = \bar{y}\ 1 - \bar{y}$, $d2 = \bar{y}\ 2 - \bar{y}$, and $\bar{y} = (n1\ \bar{y}\ 1 + n2\ \bar{y}\ 2) \div (n1 + n2)$.

The Values Behind the Standard Deviation

By quadrupling the deviations, one may get around the disadvantage of disregarding signals in mean deviations.

Appropriate for further mathematical investigation.

The one least impacted by the inherent variability of the observations

If all of the observations remain the same across time, the standard deviation will equal zero.

Unaffected by a shift in the point of origin

The positive aspects of deviating from the norm

It is not simple to compute.

Difficult to comprehend for the average person

Depending on the degree to which the scale is altered

The value of the dispersion coefficient

Whenever we wish to make a comparison between the two series, despite the fact that their averages are quite different from one another. In addition, instances in which the unit of measurement varies. In addition to calculating the dispersion measure, we need to also compute the coefficients of dispersion. The coefficients of dispersion, abbreviated as C.D., are calculated using a variety of metrics of dispersion.

Based on Range = (X max – X min)⁄(X max + X min).

The coefficient of variation, based on the quartile deviation, is calculated as (Q3 – Q1) (Q3 + Q1).

Calculated based on the mean deviation, which is defined as the standard deviation divided by the average.

The formula for calculating standard deviation is as follows:

Variational Coefficient of Error

The coefficient of variation equals the coefficient of dispersion multiplied by 100. It is calculated using the standard deviation (C.V.).

C.V. = 100 (Standard Deviation / Mean) = (/) 100

Example Formulation Regarding the Measurement of Dispersion

The values of the findings for both Company A and Company B are included in the following table, which can be found below.

	Company A	Company B
Number of employees	900	1000
Average daily wage	Rs. 250	Rs. 220
Variance in the distribution of wages	100	144

Which of the companies has a higher total payroll expense?

Perform the necessary calculations to determine the coefficients of variation for both of the businesses.

Determine the daily average salary as well as the standard deviation of the wage distribution for all of the workers that work for both companies A and B combined.

Solution:

Regarding Company A

The number of workers is equal to 900, and the average hourly salary is equal to Rs. 250.

We are aware that the formula for calculating the average daily salary is total wages divided by the total number of workers.

Alternatively, Total Wages = Total Employees Times Average Daily Wage = 900 Times 250 = Rs. 225,000... (i)

Regarding Company B

The number of workers is equal to n2 = 1000, and the average hourly salary is equal to 2 = Rs. 220.

Therefore, Total Wages equals Total Employees times the Average Daily Wage, which is 1000 times 220, which equals Rs. 220000... (ii)

When we look at I and (ii), we see that Company A has a higher total payroll expense.

Regarding Company A

The standard deviation of the pay distribution is 12 times 100.

The coefficient of variation of wages is equal to one hundred times the standard deviation of the pay distribution divided by the average daily salary.

Or, C.V. A = $100 \times \sqrt{100/250} = 100 \times 10/250 = 4$ … (i)

Regarding Company B

The standard deviation of the pay distribution is - 22 times 144.

C.V. B = $100 \times \sqrt{144/220} = 100 \times 12/220 = 5.45$ … (ii)

When we look at I and (ii), we see that Company B has a larger degree of variability.

When Companies A and B are considered together

When both firms are considered combined, the average daily pay are as follows:

$\bar{\bar{y}} = (n_1 \bar{y}_1 + n_2 \bar{y}_2)/(n_1 + n_2) = (900 \times 250 + 1000 \times 220) \div (900 + 1000) = 445000/1900 = \text{Rs. } 234.21$

The combined variance, $\sigma^2 = (1/n_1 + n_2) \div [n_1 (\sigma_1^2 + d_1^2) + n_2 (\sigma_2^2 + d_2^2)]$

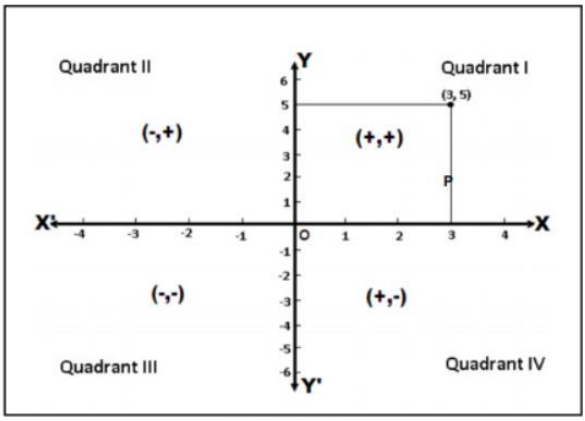
Here, $d_1 = \bar{y}_1 - \bar{\bar{y}} = 250 - 234.21 = 15.79$, $d_2 = \bar{y}_2 - \bar{y} = 220 - 234.21 = -14.21$.

Hence, $\sigma^2 = [900 \times (100 + 15.79^2) + 1000 \times (144 + -14.21^2)]/(900 + 1000)$

or, $\sigma^2 = (314391.69 + 345924.10)/1900 = 347.53$.

Graphical representation of Data

The display of facts and information may also be done via the use of graphical representations, in addition to diagrams. The presentation of time series and frequency distributions is often done via the use of graphs. In this piece, we will discuss the graphical display of data and information, including its advantages and disadvantages, as well as the many formats it may take.



Building a Graph from Scratch

The graphical representation of facts and information provides a fast and straightforward method for comprehending the characteristics

and making comparisons. Additionally, it is a useful analytical tool, and a graph may assist us in locating the mode, median, and other important values.

We are able to determine the location of a point on a plane by using two lines that are perpendicular to one another: the X-axis, which is the horizontal line, and the Y-axis (the vertical line). The Origin is located at the spot where these two paths meet.

We are able to determine the location of a point by using the distance that it is from both of these axes. For instance, if a point P is located 3 units away from the Y-axis and 5 units away from the X-axis, then the following information may be used to determine its location:

Graphical Plane

Several things to keep in mind:

We take a measurement along the X-axis to determine how far away the point is from the Y-axis. In a similar manner, we determine how far the point is from the X-axis by measuring its distance along the Y-axis. As a result, in order to measure three units away from the Y-axis, we must travel three units along the X-axis, and the same logic applies to the opposite coordinate.

After that, we will draw lines that are perpendicular to these two spots.

The location of the point P is determined by the intersection of the perpendiculars at this point.

The notation for it is as follows: (3, 5) or (abscissa, ordinate). They constitute the coordinates of the point P when taken together.

The word "Quadrant" refers to each of the four sections of the aircraft.

Additionally, we are able to plot unique points for each unique combination of value.

Standard Operating Procedures for the Visual Representation of Data and Information

There are certain recommendations to follow in order to create a graphical representation of facts and information that is both appealing and useful. The following describe each of these:

Appropriate Title - It is imperative that you provide the graph with an appropriate title that unmistakably communicates the nature of the material that you will be presenting using the graph.

Below the title, you should provide the unit of measurement in a way that is easy to understand.

Select an Appropriate Scale It is important that you select an appropriate scale so that you can accurately portray all of the data.

Index: Include a short index that describes the various colours and shades, lines and patterns that you have used in the graph. This should be done at the end of the graph. In addition, a scale of interpretation should be included for improved comprehension.

Data Sources Whenever it is feasible to do so, include a list of the information's origins at the very bottom of the graph.

Keep It Simple - When creating a graph, you should aim to create something that even a person who has had no prior experience in the fields of statistics or mathematics can comprehend.

A graph is a handy visual tool that may be used to convey facts and statistics in an organised fashion. As a result, you are obligated to maintain its tidiness and attractiveness. Pick the proper dimensions, the right text, and the right lines, colours, dashes, and other elements.

The Positive Aspects of Graphs

The data is presented in a form that is much simpler to comprehend thanks to the graph.

In contrast to tables, it enables us to show statistical information in a format that is visually appealing. At a glance, users are able to comprehend the primary characteristics, patterns, and variations included within the data.

Time may be saved with a graph.

The user is given the ability to compare data pertaining to two distinct time periods or geographical areas.

A viewer does not need to have any previous understanding of mathematics or statistics in order to comprehend the information shown in a graph.

Finding the numbers that represent the mode, median, and mean of the data may be accomplished with the use of a graph.

It may be helpful for making predictions, as well as when interpolating and extrapolating data.

Constraints imposed by a Graph

A graph does not display information with total precision.

It just illustrates a small number of carefully chosen aspects of the data.

We are unable to utilise a graph as evidence to support our claim.

A graph is not an acceptable replacement for tables.

In most cases, it might be challenging for non-experts to comprehend and make sense of a graph.

In most cases, a graph will display an implausible trend in the data, but the real values will remain obscure.

Different kinds of graphs

There are two distinct kinds of graphs: graphs depicting a time series diagrams showing the distribution of frequencies

Time Series Graphs

A graph known as a "histogram" or a "time series graph" is one that illustrates the value of a variable over the course of a number of distinct points in time. In a graph depicting a time series, time is the

most significant variable, and the variable is connected to time in some way. It is helpful in understanding and analysing the changes that occur in the variable at various points in time. These graphs are used by a lot of statisticians and businesspeople since they are simple to grasp and also because they present complicated information in an easy-to-understand way.

In addition, the user does not need to have any specific technical abilities in order to design a time series graph. The building of a time series graph consists of a number of important phases, which are as follows:

Place the passing of time along the axis labelled "X," and the value of the variable along the axis labelled "Y."

The Y-value should begin at zero, and you should think of an appropriate scale that will let you show all of the data in the space that is available to you.

Create a graph of the variable's values while connecting the various points with a straight line.

It is possible to plot numerous variables using a variety of lines.

Line Graph

You may make a summary of how two different pieces of information are connected to one another and how they fluctuate with one another by using a line graph.

Advantages

You can compare numerous continuous data-sets simply

From the line on the graph, you may deduce the data during the interim period.

Disadvantages

Only continuous data may be utilised with this method.

Utilization of a fictitious base line

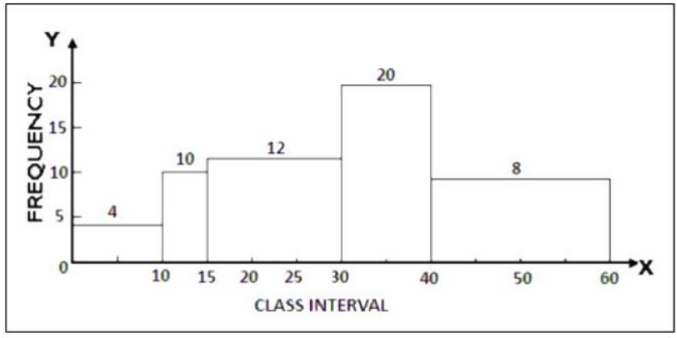
In a graph, the Origin is often the point at which the vertical line begins. However, in some circumstances, a fabricated Base Line will

be used in order to get a more accurate depiction of the data. There are two instances in which you should make use of a fictitious Base Line:

In order to emphasise the relatively little changes that occur in the time series,

In order to make the most efficient use of the area

Net Balance Graph

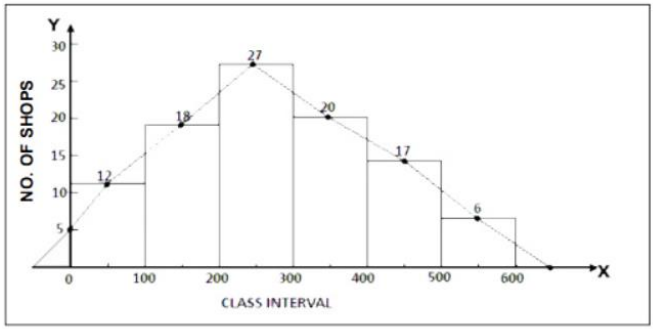


If you need to demonstrate the net balance of income and expenditures, revenue and expenses, imports and exports, or anything else along those lines, you will need to utilise a graph that shows the net balance. You may utilise a variety of hues or tones to differentiate between good and negative aspects.

Graphs Showing the Distribution of Frequencies

Let's have a look at the many forms of graphs that represent frequency distributions.

Histogram

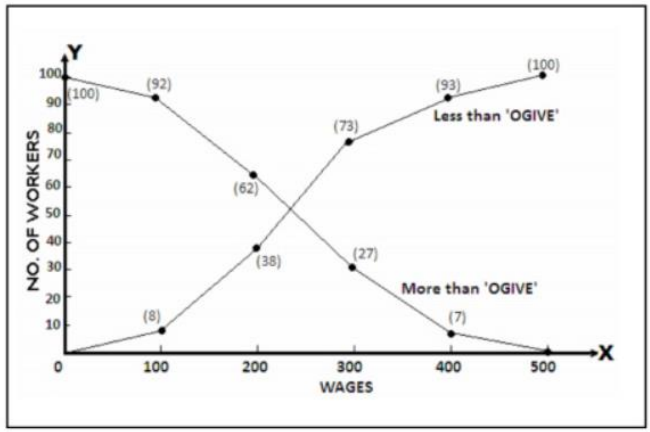


A graph of a clustered frequency distribution is referred to as a histogram. The class intervals are shown along the X-axis of a histogram, and the relative frequencies of each class are plotted along the Y-axis. In addition to this, we draw a rectangle on each class interval, with the height of the rectangle being proportional to the frequency density of the class.

Histograms as well as Frequency Polygons

On a graph, another means of displaying a frequency distribution is by the use of a frequency polygon or a histograph. To create a

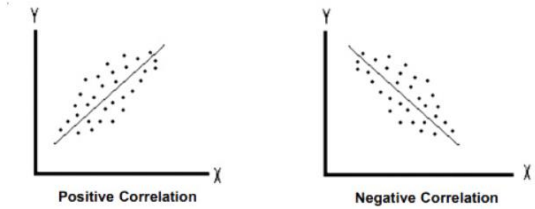
frequency polygon, you start by drawing a histogram. Then, you take the midpoints of the top widths of the rectangles that are adjacent to each other and unite them with straight lines.



FREQUENCY POLYGON

Diagram Showing the Frequency Curve

A Frequency Curve is the name given to the figure that is produced when the verticals of a polygon are connected by means of a smooth curve. As the total number of observations grows, we will need more classes to handle the workload. As a result, the breadth of each class becomes narrower. In this kind of situation, the variable has a greater likelihood of becoming continuous, and the frequency polygon will begin to take on the form of a frequency curve.



The Cumulative Frequency Curve, Also Known as the Ogive

The graphical depiction of a cumulative frequency distribution is called an Ogive, often known as a cumulative frequency curve. Ogives may be divided into two categories: "less than ogives" and "more than ogives" due to the fact that the kind of cumulative frequency can either be "less than" or "greater than."

Scatter Diagram

The nature of the connection that exists between the variables may be determined with the use of a dot chart or a scatter diagram. If there is a large amount of dispersion between the plotted points, then there is less of a correlation between the two variables.

Illustrations of Inferential Statistics

Because it is possible to form conclusions about the population even while the entire data have not been collected, inferential statistics is a particularly helpful and cost-effective method of statistical analysis. The following is a list of some instances of inferential statistics:

Assume that the average grades of one hundred students from a certain nation have been determined. Inferential statistics allow for an approximation of the mean marks earned by students throughout the nation based on the information provided in the sample.

Imagine that a coach at a college wants to find out how many average cartwheels sophomores at his school can do in a row without pausing. A random selection of students will be questioned about their ability to do cartwheels, and then the average will be determined. This information will be used using inferential statistics to draw a conclusion on the average number of cartwheels that sophomores are capable of doing.

Statistics based on inference vs statistics based on description

Both descriptive and inferential statistics are used in the process of describing data and drawing conclusions about the population based on samples taken from the population. The differences between inferential statistics and descriptive statistics are compared and contrasted in the table that follows.

When working with inferential statistics, the goal is to arrive at conclusions that go beyond what can be drawn from the immediate data alone. For instance, we make use of inferential statistics to make an educated guess about what the general population would believe based on the sample data. Alternately, we may use inferential statistics to make judgements about the possibility that a difference between groups that was seen is a reliable one or one that could have occurred by chance in this research. Therefore, we use inferential statistics to draw conclusions about more general circumstances based on our data and descriptive statistics to simply explain what's going on in our data. Inferential statistics are used to draw conclusions about more general conditions based on our data.

In this section, I will focus on inferential statistics that may be helpful in the design of experimental and quasi-experimental research as well as in the assessment of the outcomes of programmes. When you wish to compare the average performance of two groups on a single measure to determine whether or not there is a difference, you may apply what is perhaps the most straightforward kind of inferential test. You could be interested in finding out whether there is a difference in the math test scores of eighth-grade boys and girls, or if there is a difference in the end measure between a programme group and a control group. When you want to compare the average performance of

two groups, you should think about using the t-test to look for differences between the groups whenever you do this.

The Broad Linear Model is a general family of statistical models that is responsible for producing the majority of the most important inferential statistics. This encompasses the t-test, the Analysis of Variance (ANOVA), the Analysis of Covariance (ANCOVA), regression analysis, and a great deal of the multivariate techniques like as factor analysis, multidimensional scaling, cluster analysis, discriminant function analysis, and so on. In light of the significance of the General Linear Model, it is recommended that every social researcher who takes their job seriously familiarise themselves with the GLM's methodology. The description of the General Linear Model presented here is quite fundamental, and it only takes into account the most fundamental model, which is the straight-line model. On the other hand, it will acquaint you with the concept of a linear model and help you prepare for the more complicated studies that will be discussed further on.

The concept of a "dummy" variable is one that should be familiar to everyone who is interested in learning how to compare different groups. The term does not imply that we are making use of variables that are not very intelligent or, even worse, that the analyst who makes use of them is a "dummy"! These variables could be better understood if they were referred to as "proxy" variables. A dummy variable is just a variable that employs discrete integers, generally 0 and 1, to represent various groups in your research. These numbers may be either positive or negative. The use of dummy variables is a straightforward concept that paves the way for the execution of quite complex operations. For example, if I include a straightforward dummy variable in my model, I may model two distinct lines—one for each treatment group—using only a single equation. Check out the section on dummy variables to have a better understanding of how this works.

A comparison of the programme group and the non-program group on the outcome variable or variables is one of the most essential studies that can be performed when evaluating the results of a programme. The study design that we adopt will determine how we go about doing this. Experimental and quasi-experimental designs are the

two primary categories that make up the broad category of research designs. The analyses of each are provided individually because of the differences between them.

Experimental Analysis

The straightforward randomised experiment with merely a posttest for two groups is often evaluated using either the one-way ANOVA or the basic t-test. The Analysis of Variance (ANOVA) Model is often used in order to conduct the analysis of the factorial experimental designs. Randomized Block Designs make use of a subtype of the ANOVA blocking model known as the "dummy-coded variable method" to represent the different sections of the study. It should come as no surprise that the Analysis of Covariance statistical model is the one used in the Analysis of Covariance Experimental Design.

Quasi-Experimental Analysis

The experimental designs and the quasi-experimental designs both vary in that the quasi-experimental designs do not employ random assignment to allocate units (such as individuals) to the different programme groups. Analysis of these designs is often made much more difficult by the absence of a random assignment component. For instance, in order to conduct an analysis using the Nonequivalent Groups Design (NEGD), we have to use a model that is often known as a Reliability-Corrected Analysis of Covariance and alter the pretest scores so that they account for the possibility of measurement error. When using the Regression-Discontinuity Design, we need to be particularly wary of curvilinearity and the possibility of model misspecification. As a consequence of this, we have a tendency to apply a conservative analytical technique that is based on polynomial regression. This strategy begins by overfitting the probable true function, and then reduces the model depending on the outcomes of the process. The Regression Point Displacement Design only incorporates a single treatment unit within its structure. Nevertheless, the conventional ANCOVA model is used as a foundation for conducting the analysis of the RPD design.

When you've looked at all of these different analytical models, you'll find that they all belong to the same family—the General Linear Model—and that this will become clear to you. If you have a good knowledge of that model, you will be well on your way to being familiar with the complexities of data analysis in the context of applied and social research.

Statistics that rely on inferences

When comparing the differences that exist between the treatment groups, inferential statistics are often used. Inferential statistics are used to compare the treatment groups and to draw generalisations about the wider population of participants. These statistics are derived from measurements taken from a sample of the people who participated in the experiment.

There is a wide variety of inferential statistics, each of which is suitable for a particular study design and the features of a sample in a particular context. In order for researchers to determine the appropriate statistical test for their experiment, they need review the various books that are available on experimental design and statistics. On the other hand, the vast majority of inferential statistics are predicated on the idea that the value of a test statistic is derived by applying a specific formula to the data. This number, in conjunction with the degrees of freedom, a measurement linked to the sample size, and the rejection criteria, are used in the process of determining whether or not there are differences between the treatment groups. The greater the size of the sample that is being analysed, the greater the likelihood that a statistic will suggest that there are differences between the treatment groups. Therefore, the more people that are included in the sample, the more convincing the statistic is regarded to be.

Almost every kind of inferential statistic relies on an essential assumption in the background. It is expected that each replication inside a condition may be considered independent. That is to say, it is believed that any value inside a condition is unrelated to any other value within the sample. Researchers that study animal behaviour often face a variety of obstacles because they work under the notion that animals are independent.

Statistics that allow for inferences to be drawn about a situation or event are called inferential statistics. In this manner, it is fundamentally different from descriptive statistics, which only report the data that has been really measured. It gives you the ability to make inferences based on extrapolations, which is a key distinction between the two. Let us return to our earlier example of a party. It has been said that comparison data indicate that the parties that your buddy Sophia throws are quite successful (e.g., the average number of attendees and the median duration of her parties are greater than those of other parties). Your following queries can revolve on the reasons behind her gatherings' overwhelming popularity. Is it the alcoholic beverages she provides, the food she serves, the size of her social network, the prestige of her job, the number of men or women she knows, her physical attractiveness, the number of men or women she knows, her number of friends, the size of her residence, the location, or some combination of these factors? You may find that inferential statistics are helpful in responding to these issues. The fact that parties with lower attendance levels had, on average, less beverages offered would lead one to believe that the drinks provided by your friend Sophia are likely the critical component. In order to come to any conclusions, the disparities between her events and other parties, in terms of attendance and the kind of beverages provided, would need to be substantial enough.

It is important to keep in mind that inferential statistics almost always imply, but are unable to definitively establish, an explanation or a cause-and-effect link. The term inferential originates from the verb "infer." According to the American Heritage Dictionary, to infer is to draw a conclusion or make a judgement based on premises or evidence, but not to prove anything. Statistics that are used in an inferential manner are those that examine a subset of a larger population in order to derive conclusions about the larger population as a whole. Estimation, or making educated guesses about the characteristics of a population based on a sample of that population, and hypothesis testing are two of the most common components of inferential statistics (i.e., finding evidence for or against an explanation or theory).

The study of statistics involves describing and analysing variables. In Chapter 4, we go further into discussions on measurements and variables. A measurable quality or aspect of anything that may take on a variety of values is referred to as a variable. A variable may either be quantitative, such as height, or categorical, such as gender (e.g., eye color). Variables may either be independent, in which case the value they adopt is not influenced by any other variables, or reliant on the values of other variables (the value it assumes is pre-determined by other variables). Variables are neither necessarily independent or dependent. An independent variable in one statistical model may be dependent on another. Imagine, for the sake of this illustration, that we had a statistical model to utilise in determining what causes heart disease. The risk factors for heart disease would be independent variables. These risk factors include the number of cigarettes smoked per day, beverages consumed per day, and cholesterol level. A dependent value would be considered to be the existence of heart disease. The existence of heart disease is affected by the many risk factor factors.

Statistical approaches may either study one variable at a time (also known as univariate analysis) or several variables simultaneously and all at once (also known as multivariate analysis) (i.e., multivariate analysis). Analysis of bivariates involves looking at two variables at the same time. A straightforward investigation of the mortality rates of various nations is an example of a univariate study. [Case in point] An investigation of the connection between drunkenness and premature death is a good illustration of a bivariate study.

Testing a statistical hypothesis may lead to errors of two types: type I and type II.

A quantitative strategy for determining whether or not the null hypothesis (H0) should be rejected is made available by inferential statistics. In an inferential test, there are only two potential right outcomes since H0 must either be true or false; the first is the proper rejection of H0 when it is false, and the second is the correct retention of H0 when it is true. As a result, there are two distinct kinds of mistakes that might take place, which have been designated as Type I

errors and Type II errors respectively. When H0 is wrongly rejected, this is referred to as a type I error. This is what is known in the industry as a false positive. When H0 is allowed to stand despite the knowledge that it cannot be true, this is a type II mistake. A false negative is the conventional name for this kind of inaccuracy. When it comes to repeatability, having a solid understanding of the likelihood of committing type I or type II errors is very necessary. This likelihood is dependent on the design and execution of the experiment, as well as the size of the sample, which once again emphasises the need of power analysis.

Comparison of Inductive and Transductive Inference, as well as Sample and Population Statistics

The field of statistics known as inferential statistics is concerned with drawing conclusions about populations by analysing samples. How can we make inferences about the whole collection of instances, taking into account other particular cases that are part of the complete set, if we only have knowledge about a portion of the examples? When drawing conclusions based on the principles of evidence, sample statistics are used. Our research leads us to believe that matching and similarity-based judgments are supported by population statistics. That is, if one has sample statistics, then the inferential issue to solve is how to interpret those statistics as evidence, and this difficulty arises only if one has sample statistics. If one has population data, the inferential difficulty becomes determining the degree of fit between the two groups. Psychologists are quite knowledgeable when it comes to inferential statistics and the interpretation of evidence: In general, the findings of our investigations allow us to make inferences about populations based on samples. We very seldom, if ever, have information on every single member of the population. What are some examples of conclusions that may be drawn from population statistics? Thankfully, there is a description of population-statistical inferences, as well as a name for this kind of inference: Transductive.

The phrase "transductive inference" was coined by Piaget and is common parlance in the field of developmental psychology (1959). Piaget called the preoperational mode of reasoning that connects specific cases without any general rule or underlying mechanism "transductive," and he used this term to describe that mode. It is reasonable to assume a causal connection between two events just because they occurred close together. The lights went out after a honk from an automobile horn; the horn was the source of the darkness. The conclusion is drawn from a specific occurrence (the honking) to another occurrence (the darkness), but there is no suggestion of a general process. To clarify, how exactly may blaring horns bring about darkness? How might this relationship be maintained on a larger scale? It would seem that Piaget's transductive inference is a kind of sympathetic magic's "principle of connection" (Frazer, 1894; events perceived together are taken to be causally related). A Humean or associative view of causality and causal inference both share this concept as one of its distinguishing features: The simple act of seeing a connection between two things constitutes a causal link. When someone first connects horns with darkness, they will begin to anticipate the presence of the former given the latter. Therefore, it would seem that known associative learning and similarity-based induction underlie the process of transductive reasoning (horn = darkness). Perhaps Piaget was trying to illustrate some specific qualities of young children's similarity-based inferences (for example, "one-trial" connections), but the basic process of inference is something most people are already acquainted with. In particular, it is not quite obvious how Piaget's transductive reasoning handles the issue that conclusions based on similarity depend on population statistics. On the other hand, there is an alternative theory of transductive reasoning that does.

Vladimir Vapnik is credited as being the one who first brought the term "transductive inference" into the literatures of machine learning and statistical learning theory, seemingly independently of Piaget (1998). Vapnik also uses the term "transductive" to refer to conclusions drawn from specific instances based on those same specific examples. Transductive inferences, on the other hand, are,

according to Vapnik, a kind of simplifying assumption and a technique of handling difficult learning challenges. According to Vapnik's argument, statistical inference—the kind that uses evidence and is considered standard—is an effort to answer a more general issue. How is it possible for a learner to derive a rule or pattern from their previous experience with a collection of instances that can then be applied to new examples? The fact that there is an unlimited number of possible fresh instances is the most important aspect of evidentiary inference. The idea behind transductive reasoning is that it is possible to draw just a limited number of conclusions from a given set of data. For instance, an inspector may run into the challenge of determining which of a batch of one hundred widgets are flawed (see Fig. 1.1). In most cases, finding a solution to the issue with a specific batch will be a great deal less difficult than finding a solution to the challenge of recognising faulty widgets in general. According to Vapnik, the method of transductive inference is the practise of confining one's emphasis to the particular instances that the learner will actually come into contact with. In order to access Piaget's transductive inference, please click here. If the child's conclusion that horns produce darkness is limited to the specific scenario in which it was witnessed, then the issue looks to be less severe: The problem arises only when it is extrapolated outside its own context. In a similar vein, the connection between sample statistics and population statistics becomes clearer. In (traditional, evidential) statistical inference, the sample size is equal to one hundred widgets. The goal of this activity for the student is to construct a representation of the class or population of widgets using this sample. The population for the purpose of transductive inference is the one hundred widgets. The learner's mission is to acquire and use statistical knowledge in order to formulate hypotheses on this population.

The connection between evidential-sample inferences and transductive-population inferences may be better understood with the assistance of an example. Consider the one hundred different widgets. Imagine that an inspector has gone over all 100 of them and found the following issues: There are a total of 100 widgets, 10 of which are black and 90 of which are white. Furthermore, five of the black widgets are broken, while nine of the white are broken. These are statistics that

describe the population. Inferences need to be drawn from these descriptive data, which presents a problem for the inspector. Transductive inferences and evidential inferences, or what we have been referring to as "ordinary statistical inferences," are the two types of inferences that we differentiate here. The inspector may be asked to make either kind. The statistics that were observed are examples of population statistics if the inference is about the hundred widgets. Take, for instance, the scenario in which the inspector is presented with one of the widgets and informed that it is white. The inspector is certain that there won't be any problems since just ten percent of the white widgets had defects in the past. This is an example of an inductive inference, which may be characterised by the fact that its validity cannot be established with certainty: The judgement is likely to be correct given the inspector's previous work, but it is not absolutely definite. However, this is an example of a certain kind of inductive inference known as a transductive inference. The difficulty that the inspector is facing is not too complicated. After determining that the descriptive statistic p(defective|white) equals 0.1, there is, in reality, very little work left to be done. Because the descriptive statistic was computed on the basis of the instances that the inspector is using as a basis for his conclusions, the inspector may confidently use the descriptive statistic as a guide for his inferences. The inspector is only providing a description of the population; he or she is not drawing any conclusions at all from this information. It doesn't seem like much of a leap in inductive reasoning to go from "nine of these ninety white widgets are defective" to "one of these white widgets has a ten percent chance of being defective" to "a white widget chosen at random is probably not defective." This progression goes from "nine of these ninety white widgets are defective" to "one of these white widgets has a ten percent chance of being defective." To put it another way, after the inspector has solved the descriptive issue (what percentage of the 100 widgets are faulty or white?), the inferential challenge, which is to make a prediction about a widget that was randomly chosen, is simple.

When it comes to drawing conclusions about a widget that was not included in the "training" set, Widget 101 presents the inspector with a more challenging challenge. In this scenario, the descriptive

statistics (such as the value p(defective|white) = 0.1) are characteristics of a sample, and the inspector is tasked with calculating inferential statistics in order to formulate predictions. In this scenario, the inspector has to think about the evidentiary connection between his sample (which consists of one hundred widgets) and the whole population (from which the new widget was drawn). Is there a bias in the sample? One particular challenge of evidentiary inference is the identification and correction of any sample bias that may exist. This particular inferential difficulty is what differentiates evidential inference from its counterpart, transductive inference. When drawing a transductive inference to one of the 100 original widgets, the sample bias does not important.

Take, for example, the challenge of determining what colour a gadget that has been deemed faulty will be. If the faulty widget was one of the 100, then it is easy to make a forecast about its colour: it is most likely white. White was the most common colour for the 14 faulty widgets that were found. If the faulty widget is a brand new one, like widget 101, the forecast is cloudier. The majority of the original 100 widgets were white in colour. Is it representative of the widgets in the general population, or is it due to a bias in the sample? It is impossible for the inspector to draw conclusions about the whole population based on the results of his sample alone unless he is aware of the connection that exists between the two. To make a transductive inference, however, it is not necessary to determine that connection or find a solution to this inferential difficulty. There is no evidence of sample bias if the one hundred widgets are used to represent the population. In this sense, transductive inference may be used in the same manner as inductive inference, namely as a form of simplifying assumption. Inductive reasoning is called transductive reasoning when the relationship between the sample and the population is neglected and the statistics from the sample are handled as if they were population data. The difficulty of transductive reasoning is restricted to the process of constructing effective descriptions (characterizing the patterns in the available data).

UNIT 5
INTERPRETATION AND REPORT WRITING

RESEARCH REPORTS: DEFINITION

After doing structured research, often in the form of surveys or qualitative approaches, researchers and statisticians would compile recorded data known as research reports after completing analysis on the information they have gleaned from the study.

Reports often cover a wide variety of subject areas, but their primary purpose is to provide information on one specific subject area to a relatively specific subset of the population as its target audience. The fundamental objective of research reports is to communicate significant findings from a study to marketers so that they may incorporate those findings into the formulation of new tactics. Those in authority need to be informed of certain occurrences, facts, and other information based on incidents, and the most effective method of communication is the production of research reports. In an ideal research report, the material that is provided is exceedingly accurate, and the report also has a crystal clear aim and conclusion. In order for these reports to be useful in conveying information to readers, the format they are presented in should be clear and organised.

In most cases, a research report is believed to be a truthful witness of all the effort that was done to acquire specifics of study. A research report is a dependable source that recounts information about a research that was completed.

The following are the many parts that make up a research report:

1. Summary
2. Background/Introduction
3. Methods That Were Put Into Practice
4. The Outcomes Determined by the Analysis
5. Deliberation

6. Conclusion

The researcher is responsible for completing the task of drawing conclusions after completing the process of gathering and evaluating the data, followed by the task of producing the report. It is essential that this step be carried out with extreme caution; otherwise, erroneous inferences may be formed, and the whole point of doing research may be rendered moot. The researcher will not be able to reveal the linkages and processes that lie behind his results unless he or she engages in the process of interpretation. Throughout the case of studies that test hypotheses, the researcher may come to generalisations if the assumptions are tested and sustained several times in the course of the study. In the event that the researcher did not have a hypothesis to begin with, however, he or she would attempt to explain the data using some theory. This might sometimes result in new questions, which would then lead to more research. All

This analytic information and the resultant inference (or inferences) might very well be conveyed to the consumers of research findings, ideally in the form of a research report. Consumers of research results could be people, groups of persons, or public or private organisations.

MEANING OF INTERPRETATION

After conducting an investigation that is analytical or experimental, the next step is to perform the work of interpretation, which entails deducing meaning from the data that have been gathered. In point of fact, it is an investigation of the potential ramifications of the results of study. The undertaking of interpretation may be broken down into two primary components:

I the process of attempting to maintain continuity in research by tying the findings of one study to those of another, and

(ii) The formulation of a few conceptual frameworks for explanation. "Interpretation, in a sense, is concerned with connections within the data that were obtained, somewhat overlapping with analysis. In addition to the findings of the study itself, interpretation also takes into account the findings of other studies, as well as theories and hypotheses.

(iii) Therefore, interpretation is the tool that allows for a better understanding of the aspects that seem to explain what the researcher has seen over the course of the study, and it also gives a theoretical conception that may serve as a guide for additional inquiries.

The significance of interpretation lies in the fact that it is via accurate interpretation that the results of research may be put to beneficial and practical use. Because of the following reasons, it is now being regarded as a fundamental part of the research process:

The researcher will not have a complete understanding of the abstract principle that lies underneath his results until he or she has interpreted those findings. Because of this, he is able to connect up his results with those of other studies that have the same abstract concept, and as a result, he is able to make predictions about the events that will take place in the real world. In the future, these hypotheses may be put to the test via new research. In this manner, we can ensure that there is no break in the flow of research.

(ii) The process of interpretation leads to the formulation of explanatory ideas, which may be used as a map to direct the conduct of subsequent research projects; it also paves the way for new pathways of intellectual exploration and piques one's curiosity to learn more.

(iii) Only by interpretation can the researcher better realise why his results are what they are, and only through interpretation can the researcher help others understand the true relevance of his study findings.

(iv) The interpretation of the findings of an exploratory research study often leads in hypotheses for experimental research, and as such, interpretation is engaged in the shift from exploratory research to experimental research. Because an exploratory research does not begin with a predetermined hypothesis, the results of such a study are required to be interpreted in a way that does not assume anything.

METHODS AND PRACTICES OF INTERPRETATION

The process of interpretation is not a simple one; rather, it is one that calls for a significant amount of expertise and dexterity on the side of the researcher. Interpretation is a skill that can only be acquired through years of experience and repeated practise. In order to

successfully complete the process of interpretation, the researcher may on occasion decide to seek the advice of specialists. In many cases, the following procedures are involved in the method of interpretation:

The researcher is obligated to provide reasonable explanations of the relations that he has discovered, as well as to interpret the lines of relationship in terms of the underlying processes. Furthermore, the researcher is required to make an effort to discover the thread of uniformity that lies beneath the surface layer of his diverse research findings. In point of fact, this method is the methodology that should be used when generalising, and it is also how ideas should be constructed.

(ii) If any extraneous information was gathered during the course of the research study, it must be taken into account when interpreting the findings of the research study as a whole because it has the potential to become an essential component in better comprehending the issue that is being considered.

(iii) Before going into final interpretation, it is preferable to seek the advice of someone who has insight into the topic in question, as well as someone who is forthright and honest, and will not be bashful in calling attention to gaps and inconsistencies in logical arguments. A consultation of this kind will lead to the accurate interpretation of the data, which will, in turn, increase the value of the findings of the study.

(iv) In order to prevent making incorrect generalisations, the researcher must not proceed with the work of interpretation until all pertinent aspects impacting the situation have been taken into consideration. It is essential that he take his time when analysing the data since there is a good chance that the conclusions, which at first glance seem to be correct, are really not at all accurate.

THE ELEMENTS THAT COMPRISE INTERPRETATION AND WRITTEN REPORTS

There is a possibility that the particulars of a research report may change in accordance with the objectives of the study, but the report's primary elements will always be the same. The manner in which the market researcher gathers information also has an impact on the writing style used in reports. The following are the seven primary elements that make up an effective research report:

• Research Report Summary: An full aim as well as an overview of the research is to be contained in a summary that is the length of a couple of paragraphs. Under the section titled "Report Summary," a concise explanation is provided for each of the several aspects that make up the study. It ought to be captivating enough to draw attention to all of the important aspects of the report.

• Research Introduction: Every time a researcher writes a report, they do it with the end aim of accomplishing one or more specific objectives. In the beginning, he or she may discuss the responses that are relevant to this objective and formulate a thesis statement that will be included to aim toward answering it in depth. In this part of the document, you need to provide a solution to an essential question: "What is the present state of the goal?" If the organisation was able to determine that the aim had been accomplished after the research was carried out, or if they are still in the process of accomplishing it, this information should be included in the introductory section of the research report.

• The Research Methodology Chapter is the Most Important Part of the Report since It Contains All the Important Information. Readers are able to not only obtain knowledge about the subject at hand but also evaluate the level of quality presented in the material, and the study can also be validated by other market researchers. As a result, this part has to include a significant amount of information, with a detailed discussion of every facet of the study. It is necessary for the information to be given in a chronological sequence in accordance with its value and priority. In the event that the researchers gleaned any knowledge from previously developed methods, references should be included.

• Research Results: This area of the results will consist of a brief summary of the findings, as well as calculations that were carried out in order to accomplish the objective. In most cases, the discussion section of the report is where the exposition comes after the data analysis has been completed.

• Research Discussion: In this part, the findings are examined in extreme depth, and a comparison study of publications that may possibly exist in the same subject is also provided. Any irregularity that

was discovered while doing the study will be discussed in the section under "Discussion." In the process of putting up reports on their study, researchers will need to demonstrate how their findings will be useful in everyday life and connect the dots between theory and practise.

• References to the Research and a Conclusion: Conclude all of the results from the research while also citing each and every author, publication, or content item from which references were gathered.

One of the goals of doing research is to add new information to the store of previously accumulated knowledge. As a result of this, while you are carrying out research, you are required to record both your procedures and your results in a research report.

With the help of a research report, it is simple to summarise the results of your comprehensive study as well as any holes that call for more examination. When you are faced with the need of doing research, having the skills necessary to compile a comprehensive research report will be of great assistance to you.

What exactly is included in a Research Report?

A well-written report on research is a document that summarises the procedures, facts, and results of an inquiry that was carried out in a methodical manner. It is a significant document that provides a first-hand description of the research process and is often regarded as an impartial and accurate source of information. This makes the document very valuable.

A research report may be seen in many different ways as a summary of the research process that eloquently emphasises the results, suggestions, and other significant facts. Reading a research report that has been thoughtfully prepared should provide you with all of the knowledge that you need about the fundamental aspects of the investigation method.

Components that Make Up a Research Report

How exactly can one identify a study report when they come across one? The following are a few of the fundamental characteristics that constitute a research report:

It is an in-depth discussion of the procedures involved in the study as well as the conclusions, and it often include tables and figures.

It is written in a language that is considered to be formal.

In most cases, the author uses the third person while writing a research report.

It is educational and based on knowledge that can be verified through first-hand experience.

It follows a conventional format with headers, sections, and bullet points throughout.

It always offers suggestions for things that might be done in the future.

Different Varieties of Research Reports

The type of the study as well as the audience that was targeted are taken into consideration when classifying the research report.

The Makeup of the Investigation

Research Report Based on Qualitative Methods

The sort of report that is prepared for qualitative research is known as this. It provides an overview of the techniques, operations, and conclusions of a qualitative approach of systematic study. An chance to use one's knowledge and enhance one's abilities in the design and execution of qualitative research projects may be obtained via the use of a qualitative research report in the field of educational research.

The type of a qualitative research report is often one that is descriptive. Therefore, in addition to providing specifics on the methodology used in the study, you are required to also compose a story that is illustrative of the material.

Research Report Based on Quantitative Methods

The form of research report known as a quantitative research report is one that is composed specifically for quantitative research. Quantitative research is a sort of systematic study that, in an effort to discover answers to research questions, pays attention to numerical or statistical values. This style of research is also known as empirical research.

The researcher gives quantitative data in this kind of research report to support the study method and the results. In contrast to a qualitative research report, which focuses mostly on description, a quantitative research report utilises numbers; in other words, its primary focus is on numerical information.

Target Audience

Additionally, the audience that the research report is intended for might lend the document either a technical or popular tone. If you are dealing with a broad audience, you will need to provide a research report that is accessible to the general public. On the other hand, if you are dealing with an expert audience, you will need to submit a technical study.

Report on the Results of Technical Research

After doing research that is specific to an industry, you should provide a comprehensive document known as a technical research report. This report is very specialised since it offers information for a technical audience, which consists of people who have an above-average level of understanding in the area of study that it covers.

It is required of a researcher to offer precise information on the study process in a technical research report, including statistical analysis and sampling procedures. In addition, the way language is used is quite specialised, and it is full with jargon.

Research reports in the fields of law and medicine are two good examples of technical research reports.

The Most Famous Research Report

A research report that is written for a broad audience, or for persons who may not necessarily have any prior understanding in the area of study, is said to have widespread appeal. A well-known research report often strives to make the material it compiles available to everyone and everyone.

The fact that it is written in very easy-to-understand English makes it quite straightforward to comprehend both the results and the

suggestions. Newspaper articles and magazine articles both offer material that may be considered examples of popular research reports.

The Value of Conducting a Research Report

Knowledge Transfer: As was said before, one of the main purposes of doing research is to make a contribution to the existing body of knowledge, and the research report is the vehicle via which this contribution may be delivered. A research report is a useful tool for efficiently communicating the results of an in-depth inquiry to anybody and everyone who is interested in the topic.

Identification of Knowledge Gaps: If you have a study report, you will be able to identify areas of knowledge that need more investigation. A study report will detail the work that has been completed while also making hints about additional topics that need further in-depth inquiry.

In the field of market research, a research report may assist you in gaining a general understanding of the demands and nuances of the industry.

A research report gives you the opportunity to convey facts in a way that is clear and succinct.

It is both time-efficient and practical since you do not have to spend time explaining the conclusions of your research work in person in a research report. You may quickly distribute the report to stakeholders through email, and they can see it at their convenience.

Writing a Research Report: A Step-by-Step Guide

Writing a research report requires attention to many specifics; thus, being aware with the many criteria will be of great assistance to you in developing the perfect research report. A research report is often divided up into various parts, which enables material to be presented in a manner that is both clear and organised.

The Outline of a Research Report, Along with an Example

Title

This is the title of the in-depth inquiry that you are doing. A research report need to have a title that is clear and succinct, pointing to the study's goals, objectives, and conclusions.

Listing of Contents (Table of)

This acts similarly to a compass in that it assists readers in navigating their way through the study report.

Abstract

An overview is what an abstract is, and it emphasises all of the main components of the study, such as the methodology of the research, the data gathering procedure, and the conclusions of the research. Consider an abstract to be a condensed version of your research report that highlights the most important facts in a straightforward manner.

An abstract is normally between 100 and 150 words long and gets right to the point. An abstract is always short. The arrangement known as the "5 Ws and 1 H," which consists of "What, Where, Why, When, Who, and How," should serve as the primary emphasis of your research abstract.

Introduction

In this section, the researcher will discuss the goals and objectives of the systematic inquiry, as well as the issue that the researcher will attempt to address using the results of the systematic investigation. When you are writing the opening to the report, it is also very important to state whether or not the goals of the study were accomplished or whether or not further work is required.

The researcher explains the relevance of the systematic inquiry as well as the research topic that they are attempting to solve in the opening portion of the paper. Additionally, it is required of the researcher to provide an explanation of any jargons or terminology that are included in the study.

Literature Review

A written examination of the information that already exists in the topic of research is called a "literature review." In a nutshell, this is the part of the paper in which you provide an overview and analysis of the many research works that are pertinent to your systematic examination.

It emphasises current research information as well as areas that need future exploration and fills in gaps in knowledge that your research has aimed to cover. You may start dropping hints about your research hypothesis and the prospective ramifications it might have for the current body of knowledge in your area of study at this point in the process.

A Discussion of the Results of the Investigation

This is a comprehensive breakdown of the study procedure, including everything from the methodology to the research subjects and samples. In this section, you will be asked to offer comprehensive information about the research method, including the protocols for collecting data and conducting analysis.

You will need to offer information on the surveys, questionnaires, and other quantitative data collecting techniques that you employed in your study if you are writing a report on quantitative research. It is required of you, as the author of a qualitative research report, to explain the qualitative data collecting techniques utilised in your study. These methods may include interviews and focus groups.

Findings

You are tasked with presenting the findings of the systematic study in this portion of the report.

Discussion

This part provides a more in-depth explanation of the conclusions of the study that was discussed before. Here, you are expected to present a justification for each outcome and show whether the results are in line with your hypotheses or if other research studies have come up with similar results. In addition, you are expected to show whether or not other research studies have come up with similar results.

Conclusions

The following is a synopsis of all of the material that is included in the report. In addition to this, it discusses the relevance of the whole research.

References as well as further material

In this part, you will find a list of all of the main and secondary sources that were used for the study.

Guidelines for the Construction of a Research Report

Define the Environment in Which the Report Will Be Read

If you define the context of your research report, it will be easier for you to write a document that is both thorough and succinct. This is similar to what can be accomplished while writing an essay. Because of this, you need to make an outline before you begin writing in order to ensure that you do not leave anything out.

Define your Audience

It is crucial to write with your audience in mind since this will affect the tone of the report you are writing. When writing for a wide range of people, it's important to deliver the material in a way that's easy to understand and familiar to them. You would need to make use of technical and field-specific phrases if you were writing for a more specialist readership.

Include Notable Observations in Your Report

The purpose of presenting a research report is to provide a condensed version of the findings that you obtained after doing an in-depth inquiry. You should leave out any material that isn't related to your report and focus instead on showcasing the most crucial results and facts.

Include Illustrations

Illustrations and other visual representations of your data have to be included in your study report in some capacity. Your methodical inquiry is given more credibility when accompanied with graphs, pie charts, and other pertinent pictures.

Find the Appropriate Name for It

A good title for a research report should be succinct, specific, and include keywords from the study's subject matter. It should convey

a clear concept of your systematic study so that readers can comprehend the complete emphasis of your research from the title. This will ensure that your research is successful.

Examine the Report for Any Errors.

Make sure that you verify all of the facts by giving the document a second glance before you release it into the public domain. You should also have the report checked by another person if at all possible, and you should also put it through some kind of editing and proofreading programme.

A Guide to the Data Collection Process for Your Report

Comprehend the Nature of the Issue

When you are writing your research report, you should keep in the back of your mind that every piece of research is aimed at finding a solution to a certain issue or group of problems. If you had a better understanding of the issue, you would be better able to sort through the data you have and include just the most relevant information in your report.

Be aware of the goals that your report aims to accomplish.

This is somewhat related to the argument that was made before since, in some way, the aims of your systematic study are entwined with the goal of the research report that you are writing. If you can determine the main aim of producing a research paper, it will be much easier for you to locate the necessary material and present it in the appropriate manner.

Identify your audience

When it comes to the collecting of data for a research report, having a solid understanding of your intended audience is quite necessary. If the research report that you are writing is going to be intended for an organisation, then you should offer information that is unique to the industry, or demonstrate how the results of the study are important to the job that the firm undertakes.

Create Surveys/Questionnaires

A research technique known as a survey is comprised of a series of questions that are posed to a select population in order to collect information from those individuals. Quantitative or qualitative approaches are both acceptable here.

The questions that make up a survey are often organised in a certain way, and the process of collecting responses might either take place online or in person. On the other hand, an online survey is a more efficient technique of research data gathering than other methods since it allows you to save time and obtain information with more convenience.

Precautions for writing a research report

The efficient transmission of research results to the readers of the report is the primary objective of a research report, which serves as a channel of communication between the findings of the study provided by the researcher on the one hand and the readers of the report on the other.

Therefore, while putting up the study report, the researcher need to take in mind the following safety precautions:

1. The length of the report should indeed be kept in mind of the fact that it should cover the topic in depth, but it should also be kept in mind that it should be brief enough to sustain the attention of readers.
2. The report shouldn't be boring in any way. It should be designed in such a way that it keeps one interested.
3. The report must to have the qualities of being straightforward and staying away from ambiguity.
4. The readers of the report are primarily interested in getting a rapid understanding of the important results, and the report should give a prompt availability of the findings with the aid of charts, graphs, and statistical tables.
5. The information that is included in the report needs to have been carefully considered with the end goal of the research issue in mind.

6. It is important to avoid making any grammatical errors, and the report should be written in a manner that is in complete compliance with the guidelines for the writing of a report. Writing, including the use of quotes and footnotes, as well as the application of appropriate punctuation and the utilisation of abbreviations in the footnotes, etc.
7. The preparation of a research report need to begin with a logical appraisal of the situation.
8. The report has to highlight the policy implication related to the issue that is being considered, and it needs to assist us in making predictions about the future.
9. The report need to include an appendix with all of the relevant technical information.
10. Prior to writing the report, you should compile a bibliography listing all of the different sources of information that were used in the research project.
11. In addition to that, a decent report need to include an index of the authors and topics covered. It need to be included as an appendix at the very end of the report.
12. The report must to have an appealing format and be nice and clean, regardless of whether it is typed or printed.
13. Calculated confidence bounds need to be provided in the report as well, along with the numerous restrictions that the researcher encountered while doing his study. These should also be included in the report.
14. A excellent report has to additionally explain the purpose of the research, the nature of the issue, the methodology and analytical techniques that were used, and so on. The report need to begin with some kind of introduction that covers all of these topics.

Therefore, after outlining all of the aspects associated with the process of interpreting and writing reports, we should always bear in mind the fact that the process of writing a report is an art that can only be acquired by extensive practise and previous experience.

On the basis of a public readiness to confer the status of property, ideas, innovations, and creative expressions have been

identified as being within the purview of intellectual property rights (IPR), which is an abbreviation for intellectual property rights. IPR offer certain exclusive rights to the inventors or creators of that property, in order to enable them to reap financial advantages from their creative efforts or reputation. These rights allow the inventors or creators to profit from their creative efforts or reputation. There are many different kinds of legal safeguards for intellectual property, such as patents, copyrights, trademarks, and so on. A patent is a kind of recognition that is granted for an invention that meets the requirements of being globally unique, being non-obvious, and having an industrial use. IPR is a requirement for improved invention or creativity protection, including better identification, planning, marketing, and representation of the innovation or creativity. Depending on the area of expertise that it focuses on, each sector of the economy need to have its own IP policies, management style, strategies, and so on. The intellectual property rights strategy used by the pharmaceutical business is now undergoing significant change and will need improved concentration and strategy moving forward.

What exactly is the commercialization process?

The process through which a newly developed product or service is made available to consumers all over the world is known as commercialization. The process of going to market is done in stages, beginning with the launch of the product and continuing through large manufacturing and widespread use of it. It takes into consideration the manufacturing, distribution, marketing, sales, and customer support that are essential for a business to achieve commercial success. Commercialization is a business tactic that necessitates the development of a marketing plan, the determination of how the product will be provided to the market, and the anticipation of potential obstacles to the company's success. Gain a better understanding of the commercialization approach used by Pitt Ventures.

Advantages of Entering the Commercial Market

The commercialization of research results in the creation of new products and services that can be utilised to address some of life's most

pressing issues. These products and services can also be used to make incremental improvements to the quality of life for consumers and the effectiveness of business operations across a wide variety of domains.

Societal Benefit

The innovations that emerge from university research have the potential to have the greatest impact when they are put into the hands of those who stand to gain the most from them. These innovations can have an effect not only in the realm of healthcare but also in the realms of the environment, wellness, physical fitness, education, and industrial applications. In general, the University of Pittsburgh's focus on social benefit is the primary motivation driving its efforts to commercialise innovative technologies.

Expanding of the Economy

Bringing inventions to consumers via the process of commercialization results in economic benefits as well. Commercialization results in the generating of new money as well as the creation of new jobs locally, regionally, and potentially all over the world. This may be accomplished via the licencing of technology to other businesses or by the formation of new startup enterprises.

Partnerships with Local Businesses

The process of commercialization creates an opening for collaboration with members of related industries, financial backers, and other companies. These agreements may bring in new sources of financing that the university might use to further their research. Quite often, the university is able to provide more research and development resources to industrial partners, who in turn act as a conduit for disseminating findings to the general public. In addition, the university has the ability to produce cash, which may then be put back into research, used to pay expenses associated with commercialization, and funded to pursue entrepreneurial endeavours.

Both in terms of Recruitment and Retention

Positive publicity and increased knowledge of the University's research, inventions, and entrepreneurial culture are both outcomes of

successfully commercialising breakthroughs and bringing them to market. These achievements and the resulting publicity have the potential to aid in retaining and recruiting professors and students, in addition to new commercial and research partners.

Entrepreneurship

Both the teachers and the staff have the opportunity to interact with members of the local business community if the institution places an emphasis on entrepreneurialism and commercialization. This interaction may be useful in a variety of ways. When academics and industry work together, beneficial outcomes such as better understanding of the business sector, possibilities for career growth, and improved investor relations may emerge.

Commercialization may take many forms, such as selling a licence to an existing business or an entrepreneur to use their technology, or it might include starting a whole new business from the bottom up. Get more information about the several ways your idea may be brought to market.

The cornerstones of copyright law are novelty and permanence.

Works That Aren't Copies

When a human author alone creates a work and that work has at least some degree of originality, we refer to that work as original. Independent invention is shorthand for the act of coming up with something on one's own, without resorting to imitation. The United States Supreme Court has said that in order for a piece of work to be considered creative, it must have at least a "spark" and "modicum" of originality. There are certain things, however, that are not creative, including titles, names, brief phrases, and slogans; well-known symbols or designs; simple changes of typographic ornamentation, writing, or colouring; and simply enumeration of components or contents. Always bear in mind that the only thing that may be protected by copyright is expression; not ideas, procedures, techniques, systems, processes, concepts, or discoveries.

Work That Is Fixed

A piece of work is considered to be fixed when it has been recorded (either by the author themselves or with the author's permission) in a medium that is sufficiently long-lasting so that it may be observed, reproduced, or conveyed for more than a brief period of time. For instance, a work is considered finished after it has been written down or recorded.

A royalty is simply a regular payment that is given by the user of an asset to the asset's owner or the person who created the item in exchange for the usage of the asset. To put it another way, the person who created the asset, whether it is a mine, a patent, a book, an artistic production, etc.

The Trade-Related Aspects of Intellectual Property Rights (TRIPS) agreement protects the majority of different types of intellectual property, including copyright, patents, geographical indications, trademarks, industrial designs, trade secrets, and exclusive rights over new plant varieties. On January 1, 1995, TRIPS was officially put into effect.

Generally speaking, when people talk about academic publication, they mean the publishing of research findings. To put it another way, it refers to the findings that were presented in a written format by researchers who used scientific theories and procedures to acquire new information in their respective fields of study and then published their findings.

Journal articles, research reports, conference papers, and books are the typical forms of publishing, and previous research is used as a point of departure while also being critically explored and expanded further. The authors of these publications always cite the sources upon which they build their own arguments. This is an important aspect because it allows potential readers to look up the sources in question and determine not only whether or not the authors have correctly understood them, but also whether or not they have the opportunity to form their own opinion.

The vast majority of scientific articles are created in accordance with a format that is referred to as

IMRAD. The phrase is a representation of the first letters of the terms "Introduction," "Materials and Methods," "Results," and "Discussion." It provides an example of a pattern or structure rather than a comprehensive list of headings or components of research papers; the portions of a document that are not included are the following: the title, the authors, the keywords, the abstract, the conclusions, and the references. Additionally, some papers consist of an Acknowledgements section as well as an Appendix section. The Introduction explains the scope and objective of the study in light of current knowledge on the subject; the Materials and Methods section describes how the study was conducted; the Results section reports what was found in the study; and the Discussion section explains the meaning and significance of the results and provides suggestions for future directions of research. [Citation needed] The Introduction explains the scope and objective of the study in light of current knowledge on the subject. It is required that the paper be prepared in accordance with the directions given to authors by the Journal.

It is essential to bear in mind that there is neither a standard nor a consistent style that all journals adhere to. This is one of the most crucial things to keep in mind. Each publication publishes articles in its own unique format, yet all of them adhere to a standard set of Instructions to Authors (or other word combinations to mean the same thing).

You should FOLLOW THE JOURNAL'S INSTRUCTIONS TO AUTHORS once you have chosen a journal to which you wish to submit your manuscript. These instructions can typically be found in each volume of the journal (keep in mind that a volume may contain several numbers, and there could be multiple volumes in a year), or they can be easily accessed from the website of the journal. It is possible that some authors are not completely persuaded by the rationale behind some of these recommendations; nonetheless, it is a waste of time to dispute with the journal or complain about the directions that it provides. It is important to keep in mind that writers have the option of publishing their articles in any one of many different journals. The majority of scientific articles are written in accordance with a standardised structure known as IMRAD. These four letters

represent the initial letters of the phrases Introduction, Materials and Methods, Results, and Discussion, respectively. These do not constitute a comprehensive list of the headings or components that are included in research papers; the following are absent: title, authors, keywords, abstract, conclusions, and references. In addition, some papers have an acknowledgements section as well as an appendix (Appendices). In certain cases, some parts may be represented and/or augmented by others; for example, "Theory" may be used in place of "Materials and Methods." In addition, the Results and Discussion sections have been combined into a single section, and the word "Conclusions" has been added as the last component of the Discussion section. There has been a recent shift toward giving just the most significant components of the article and publishing any extra or "less important" aspects as "Supplemental Materials" on the website of the journal. This practise has becoming more common. Review articles often make use of alternative headings rather than IMRAD headings, and they do not include the section titled "Results and Discussion." More than the individual words that are included by the acronym, the term IMRAD refers to a pattern or arrangement. Since the American National Standards Institute (ANSI) chose to use this phrase as the norm both in 1972 and again in 1979 (ANSI 1979), the majority of research journals have opted to use it.

One of the characteristics of sound scientific inquiry is known as reproducibility, which refers to the capacity of separate researchers to reproduce an experiment or test and come up with the same or comparable findings. The ability to reproduce study results provides scientists with proof that the findings are objective and dependable and were not the product of chance or prejudice. Irreproducibility, on the other hand, may point to issues with any one of the stages of the research process, including but not limited to the experimental design, the variability of biological materials (such as cells, tissues, or animal or human subjects), the quality or integrity of the data, the statistical analysis, or the study description. In spite of the fact that researchers have been aware of the significance of reproducibility for quite some time, the issue has only recently become a pressing concern. This is due to the fact that scientists and the general public are becoming more

aware of the fact that the results of many studies that are published in journals that are peer-reviewed cannot be reproduced.

Plagiarism occurs when someone presents the work or ideas of another person as their own, either with or without the other person's consent, by incorporating the work or ideas into their own work without giving proper acknowledgment. This definition encompasses all of the content that has been published or that has not been published, regardless of whether it is in the form of a manuscript, a printed book, or an electronic file.

RESEARCH ETHICS

Objectives in the field of ethical research

1. The protection of human participants is the primary and overarching aim of this project.
2. The second goal is to make certain that research is carried out in such a manner that it is beneficial to the interests of people, organizations, and/or society as a whole.
3. The third and final goal is to investigate particular research projects and activities to determine whether or not they adhere to ethical standards. This will include looking at concerns such as the management of risks, the preservation of confidentiality, and the procedure of informed consent.

The term "research ethics" refers to the practice of applying basic ethical principles to a wide range of issues that arise in the context of scientific study.

The practice of applying basic ethical concepts to contemporary issues like as

1. The planning and execution of research including the use of animals and/or humans as test subjects
2. Multiple facets of the controversy in the academic community, including scientific misconducts (such as fraud, fabrication of data and plagiarism),
3. "blowing the whistle," also known as disclosing misconduct inside an institution to the general public or to individuals in

positions of responsibility; regulation of research, etc. The field of scientific research is the one in which the notion of research ethics has progressed the greatest.

4. The research that is conducted in the social sciences raises a unique set of challenges in comparison to the research that is conducted in the medical field.

Trust is the cornerstone upon which the enterprise of scientific investigation is constructed. Scientists have faith that the findings published by other researchers are accurate. People have faith that researchers are making genuine efforts to explain the world in a way that is objective and truthful, and that these efforts will be reflected in the findings of their studies. However, this trust will only continue to exist for as long as the scientific community makes a concerted effort to both model and pass on the principles that are associated with ethical behavior in the scientific community.

When doing research, there are a great deal of moral dilemmas that need to be carefully considered. Sociologists need to be conscious that it is their job to gain the true consent and interests of everyone who is participating in the research. This is a responsibility that they cannot shirk. They are not permitted to put any of the information they have obtained to improper use, and they are expected to maintain a certain level of moral duty toward the participants. Participants in the research have a moral obligation to have their rights, as well as their confidentiality and sensitivity, safeguarded. It is necessary to maintain the secrecy of those individuals who took part in the observation, as well as to protect their identity and privacy. According to what is stated in the BSA for Sociology, all of these ethical standards have to be honored, unless there are other reasons that are more compelling to do so, such as any behavior that is unlawful or terroristic.

The vast majority of people learn their understanding of ethical principles either at home, in schools, in religious institutions such as temples and churches, or in some other kind of social setting. Even though the majority of people get their sense of what is good and bad while they are young, moral development takes occur throughout the course of a person's whole life, and humans go through a number of

stages of growth as they become older. Given how prevalent ethical norms are, one might be excused for assuming them to be nothing more than common sense due to their widespread application. If, on the other hand, morality were nothing more than common sense, then it raises the question as to why our society is riddled with so many controversies and difficulties related to ethics.

Although everyone admits the presence of some universal ethical standards, different individuals interpret, apply, and strike a balance between these rules in accordance with their own set of values and their own experiences in life. One explanation that appears to make sense for these conflicts is that although everyone acknowledges the existence of certain universal ethical norms, these norms are interpreted differently by various people.

On the other hand, ethical standards have a tendency to be less formal and more comprehensive than legal laws, which are employed to control behaviour in the majority of nations. Legal regulations are utilised to govern most countries. Even while laws are employed in the majority of civilizations to enforce universally agreed moral standards, and even though ethical and legal concepts include many of the same ideas, it is very important to bear in mind that law and ethics are not the same thing. It is conceivable for the same action to be considered morally commendable in one setting yet immorally unacceptable in another. In addition, by using ethical ideas and concepts, we are able to analyse, evaluate, propose, or interpret laws. In point of fact, throughout the course of the 20th century, a number of proponents of social change encouraged members of society to break the law in order to voice their opposition to laws that they viewed as being immoral or unfair. They did this in order to express their disapproval of these laws. Through the use of nonviolent civil disobedience, one is able to express a political position in a way that is appropriate from a moral standpoint.

One further way to define the word "ethics" focuses on academic disciplines that explore standards of conduct, such as philosophy, theology, law, psychology, or sociology. This is an additional method to defining the word "ethics." This is another possible interpretation of the word "ethics." A "medical ethicist," for instance, is a person who examines the ethical concepts that underlie the practise of medicine.

[Further citation is required] An additional meaning of the word "ethics" is "a technique, process, or point of view for deciding how one should behave and for studying challenging circumstances and themes," and this is one way to characterise ethics. For instance, while thinking about a difficult subject like global warming, one might approach the problem from a variety of different angles, such as economic, ecological, political, or ethical, depending on which perspective they pick. An environmental ethicist may explore the ethical values and principles that are at stake in various policies related to global warming. This is in contrast to the work of an economist, who would analyse the benefits and drawbacks of various policies related to global warming.

There are numerous various areas of study, institutions, and professions, and each of them has its own set of behavioural expectations that are suited to the specific aims and goals it seeks to achieve. These standards not only help participants in the field plan their actions and activities, but they also contribute to the growth of public trust in the field as a whole. In professions such as medicine, law, engineering, and business, for instance, one is expected to conduct oneself in accordance with a set of ethical guidelines. People who participate in scientific research or any other kind of intellectual or creative activity are held to the ethical standards that apply to them because these standards support the purposes or goals of study. These standards also apply to people who engage in any other kind of intellectual or creative activity. The study of these norms is the primary subject of research ethics, a discipline of applied ethics that is explicitly devoted to the topic.

The importance of doing research in accordance with ethical standards may be attributed to a number of different factors. To begin, standards advance the goals of research, such as acquiring information, uncovering the truth, and staying away from making mistakes. For instance, laws that make it illegal to fabricate, distort, or otherwise misrepresent research findings help spread the truth and prevent people from making mistakes. Second, ethical standards promote the values that are essential to collaborative work, such as trust, accountability, mutual respect, and fairness. This is important for two reasons. First,

research frequently involves a significant amount of cooperation and coordination between a large number of different people working in a variety of different fields and institutions. For instance, many of the ethical conventions in research, such as criteria for authorship, copyright and patenting regulations, data sharing policies, and confidentiality restrictions in peer review, are all geared to preserve intellectual property interests while also fostering cooperation. The majority of researchers want to be recognized for their work, and they do not want their ideas to be taken by another person or shared too soon. Third, many of the ethical standards guarantee that researchers may be held responsible to the general public by helping to ensure that they follow the rules. For example, government laws on research misconduct, conflicts of interest, the protection of human subjects, animal care and usage, and so on are required in order to guarantee that researchers who are supported financially by the public may be held responsible to that public. In the fourth place, ethical standards in research contribute to the development of public support for research. It has been shown that individuals are more willing to provide financial support for a study project if they have faith in the reliability and objectivity of the research. In conclusion, many of the standards that govern research also promote a wide range of other essential moral and social values. These include social responsibility, human rights, and animal care, as well as compliance with the law, health and safety. Research that violates ethical standards may cause severe damage to the human and animal subjects, as well as the students and the general public. For instance, if a researcher fabricates data during a clinical trial, it may cause patients harm or even death. Additionally, if a researcher does not adhere to the regulations and guidelines relating to radiation or biological safety, it may put his own health and safety, as well as the health and safety of staff and students, in jeopardy.

CODES AND POLICIES FOR RESEARCH ETHICS

It should not come as a surprise that many different professional organisations, government agencies, and institutions have developed particular codes, norms, and policies pertaining to research ethics given the significance of ethics for the conduct of research. The National

Institutes of Health (NIH), the National Science Foundation (NSF), the Food and Drug Administration (FDA), the Environmental Protection Agency (EPA), and the Department of Agriculture (USDA) are just some of the federal agencies that have ethics guidelines for researchers who receive funding from their organizations. Other important policies regarding research ethics include the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, which was developed by the International Committee of Medical Journal Editors; the Chemist's Code of Conduct, which was developed by the American Chemical Society; the Code of Ethics, which was developed by the American Society for Clinical Laboratory Science; the Ethical Principles of Psychologists, which was developed by the American Psychological Association; the Statements on Ethics and Professional Responsibility, which was developed by the American Anthropolog (World Medical Association).

The following is an approximate and broad outline of certain ethical principles that are addressed by several codes:

1. Honesty It is essential that all scientific communications be conducted in an honest manner. Report the data, the findings, the methodology and the processes, and the publishing status with complete honesty. Do not manufacture, falsify, or distort data. Do not fool your coworkers, the organizations that award funding, or the general public.
2. Objectivity: Make it a priority to eliminate any potential for subjectivity in the experimental design, data processing, data interpretation, peer review, personnel choices, grant writing, expert testimony, and any other areas of research where objectivity is anticipated or needed. It is important to steer clear of or reduce instances of self-deception. Disclosing personal or financial interests that might potentially have an impact on research is required.
3. Integrity is keeping your word and honoring the deals you make; acting honestly; and working hard to maintain coherence between your thoughts and deeds.
4. Attention to Detail Steer clear of casual mistakes and laziness, and take the time to thoroughly and analytically assess both your own

work and that of your colleagues. Maintain thorough records of all aspects of the research process, including data collecting, study design, and any communication with organizations or publications.

5. Transparency: Share information, including outcomes, ideas, and resources. Maintain an open mind when it comes to constructive criticism and novel ideas.
6. Show veneration for various types of knowledgeable property, including copyrights, patents, and other forms of IP. Do not utilize any data, methodology, or findings that have not been published without first obtaining permission. It is important to give credit where it is due. It is important to properly thank and credit everyone who has contributed to the study. Never plagiarize.
7. Maintain confidentiality in all communications, including those that are submitted for publication, such as papers or grants, as well as documents pertaining to personnel, trade or military secrets, and patient data.
8. Responsible Publication: Publish in order to improve research and scholarship, and not simply your own career, rather than only publishing in order to advance your own career. Publication that is both wasteful and redundant should be avoided.
9. Responsible Mentoring: Offer assistance to students in the areas of education, mentoring, and advising. Foster their well-being and respect their autonomy by giving them decision-making power.
10. Respect for one's coworkers It is important to respect one's coworkers and to treat them decently.
11. Take Responsibility for Your Community: Through study, education of the general public, and advocacy, you should work to improve your community while also minimizing any negative effects it may have.
12. Non-Discrimination It is important to refrain from acting unfairly against coworkers or pupils on the basis of their gender, colour, ethnicity, or any other factor that is unrelated to their ability or honesty in the scientific field. This encompasses not just racial discrimination but but ethnic prejudice and gender discrimination as well.

13. Competence You should continue your education and pursuit of knowledge throughout your whole life in order to sustain and further increase your own level of professional competence and skill. In addition to this, you need to take measures to increase general scientific knowledge and expertise.
14. Compliance with the Law: Be aware of and abide by all applicable laws, as well as rules established by institutions and the government.
15. Treatment of Animals Researchers are obligated to show appropriate respect and compassion for the animals they use in their experiments. Experiments on animals should not be performed if they are unneeded or poorly conceived.
16. Protection of Human Subjects When conducting research on human subjects, researchers should make an effort to minimize potential risks and harms while simultaneously maximizing potential benefits; they should also respect human dignity, privacy, and autonomy; they should take extra precautions when working with vulnerable populations; and they should make an effort to distribute the benefits and burdens of research in an equitable manner.
17. There are a great number of additional actions that do not fit the definition of "misconduct," but which are nevertheless recognized as unethical by the majority of researchers. The following are examples of what are referred to be "additional departures" from appropriate research practices:

- Submitting the identical article to many publications without informing the appropriate journal editors.
- Sending the identical work to many journals without informing the editors of the other journals
- Keeping a collaborator in the dark about your plans to apply for a patent in order to establish yourself as the sole creator of the invention;
- Listing a colleague as an author on a paper in exchange for a favor, despite the fact that the colleague did not make a significant

contribution to the work, even if the colleague was included on the manuscript as an author.

- Sharing with your coworkers information that is deemed secret from a piece of writing that you are examining for a journal
- Eliminating data from a collection that contains outliers without first articulating the rationale for doing so in a paper
- Employing an unsuitable method of statistical analysis in order to bolster the relevance of your previous study.
- Skipping the step of having your work reviewed by peers and instead revealing the findings of your study at a press conference, without providing your colleagues with sufficient information so that they can evaluate your work.
- Carrying out a review of the published research without giving credit to the efforts of other researchers in the area or previous work that is pertinent to the topic at hand
- Exaggerating claims made in a grant application in order to give the impression to committee members that the work being proposed would have a substantial impact on the industry as a whole
- Lying on a resume or application for a job; this includes embellishing the facts.
- Comparing the completion times of two graduate students working on the identical research topic in order to determine who can finish it more quickly.
- Subjecting graduate or post-doctoral students to excessive workloads, ignoring their needs, or using them inappropriately
- Failing to maintain accurate records of the research
- Failing to keep research data for a length of time that is considered to be acceptable
- Using insulting language and making personal attacks in your assessment of the author's submission
- Promising a pupil a higher score for sexual favors
- Using a slur that is deemed to be racist in a scientific setting
- Deviating significantly from the study protocol that has been authorized by your institution's Animal Care and Use Committee or Institutional Review Board for Human Subjects Research

without informing either of those committees or boards of those major deviations.

- Failing to disclose a potentially harmful occurrence during a human study trial
- Misuse of animals in scientific research
- Violating the biosafety regulations of your school in a way that puts children and employees at risk of exposure to biological hazards
- Refusing to study a submitted work before rejecting it as unsuitable for publication
- Undermining the efforts of another individual
- Larceny of items such as supplies, literature, or information
- Conducting an experiment in such a way that the outcome can be predicted.
- Copying confidential information, documents, or computer programs without authorization
- Making a conscious decision to exaggerate the therapeutic relevance of a new medicine in order to maximize one's potential financial gain

The vast majority of scientists would consider these practices unethical, and some of them could even be breaking the law. The majority of these would also contravene various codes of professional ethics or standards established by the organization.

Fostering Responsible Behavior in Scientific Research

Many of you are probably curious about the reasoning for the need that you get training in research ethics. It's possible that you think you have a strong moral compass and understand what constitutes good and bad behavior. You would never knowingly create false data, plagiarize, or otherwise fake information. In point of fact, you could think that the vast majority of your coworkers have very high ethical standards and that there is no ethical dilemma in research.

Relax if this is how you're feeling. You are not being accused of operating in an unethical manner by anybody. In point of fact, the best data that we have demonstrates that unethical behavior in research is a

very uncommon occurrence, despite the fact that different estimates indicate a significant amount of variance. It has been estimated that the rate of misconduct ranges from as low as 0.01% of researchers per year to as high as 1% of researchers per year, and this estimate is based on proven occurrences of misconduct in research that was supported by the federal government (based on self-reports of delinquency on unidentified surveys).

It is obvious that having more data on this subject would be beneficial, but there is currently no evidence to suggest that the scientific community has become unethical. However, regardless of how seldom it occurs, unethical behavior in research may still have a significant influence on the field. Consider an example with the issue of crime: it does not take very many homicides or rapes in a town for the community's feeling of trust to deteriorate, and for dread and paranoia to spread across the community. The same may be said about the three crimes in science that are considered to be the gravest: fabrication, falsification, and plagiarism. On the other hand, the majority of crimes that are done in the field of science are probably not on the same level as rape or murder; rather, they are morally important transgressions that the government labels as "deviations." In addition, there are other instances in the realm of research that provide actual ethical conundrums.

Will becoming trained and educated in research ethics help lessen the amount of misbehavior that takes place in the scientific community? It is too soon to know at this point. The response to this question is going to be somewhat determined by how well one knows the factors that lead to inappropriate behavior. There are two primary schools of thought about the reasons why researchers engage in unethical behavior. The "bad apple" idea asserts that the vast majority of scientists adhere to strict ethical standards. Misconduct in the scientific community can only be committed by researchers who are morally corrupt, monetarily desperate, or mentally ill. In addition, only an idiot would engage in unethical behavior in the scientific community due to the fact that the peer review system and the self-correcting processes would ultimately uncover those who attempt to trick the system. In any event, it may be argued that taking a class on

research ethics won't have much of an effect on those who are "bad apples." According to the "stressful" or "imperfect" environment theory, misconduct occurs because various institutional pressures, incentives, and constraints encourage people to commit misconduct. These institutional pressures, incentives, and constraints include things like the pursuit of profit or fame, career ambitions, the pressure to publish or obtain grants or contracts, and inadequate supervision of students and trainees as well as inadequate oversight of researchers. In addition, proponents of the stressed environment hypothesis highlight the fact that the peer review mechanism used in the scientific community is far from ideal and that it is quite simple to game the system. It is very uncommon for erroneous or fraudulent research to be published in the public record for years before being discovered. A course in research ethics is likely to help people get a better understanding of the stresses that are associated with research environments, make people more sensitive to ethical concerns, and improve ethical judgment and decision making. This is true to the extent that research environments are an important factor in misconduct.

People who are morally weak, uninformed, or insensitive are probably more likely to engage in unethical behavior when they are put in stressful or flawed circumstances. Environmental factors likely have a role in unethical behavior as well. A course in research ethics is helpful in helping to avoid departures from norms, even if it does not prevent misconduct; this is the case even if the training does not prevent misconduct. It is possible that the majority of the deviations that take place in research are due to the fact that researchers either just do not know or have never given some of the ethical principles of study considerable attention. For instance, certain unethical authoring practices are presumably the result of years of tradition within the academic community, which, until relatively recently, was not called into serious question until now. What could possibly be wrong with it if the director of a laboratory is included as an author on each and every publication that is produced in that laboratory, even if he does not make a meaningful contribution to the work? One may make the case that this is the standard practice in the industry. What exactly is

wrong with the practice of a pharmaceutical corporation having its medical personnel "author" articles that were really written by ghostwriters? These days, ghost writers contribute to the writing of a wide variety of publications; if the use of ghostwriters is acceptable in other contexts, why not research?

The existence of conflicts of interest in research is another example of an area where there may be some ignorance or mistaken traditions. A researcher can believe that a "regular" or "traditional" financial arrangement, such as receiving stock or a consulting fee from a drug firm that finances her study, does not create any significant ethical difficulties since they are considered to be "normal" or "traditional." Or, it's possible that a university administrator doesn't see a problem with accepting a large gift from a pharmaceutical company that comes with conditions attached to it. Perhaps a physician feels that it is quite acceptable to earn a finder's fee of three hundred dollars for sending patients to participate in a clinical trial.

If "deviations" from ethical behaviour in research are caused by ignorance or a failure to critically reflect on harmful traditions, then completing a course in research ethics may assist lower the occurrence of major "deviations" by increasing the researcher's grasp of ethics and by sensitising him or her to the problems. This may be accomplished by improving the researcher's understanding of ethics and by sensitising the researcher to the difficulties. This is due to the fact that the researcher's comprehension of ethics will improve as a result of taking the course, and that the researcher's awareness of the concerns will also rise as a result of taking the course.

Last but not least, training in research ethics should be able to assist researchers in resolving ethical conundrums by acquainting them with significant ideas, techniques, principles, and methodologies that may be of value in the process of finding solutions to these conundrums. In point of fact, the problems have reached such a critical state that the NIH and the NSF have required that research ethics education be provided to graduate students.

RESEARCH ANIMAL (often abbreviated as RA)

The use of animals in scientific study is very important. Researchers put them to use in a number of contexts, including the evaluation of novel medications, the instruction of medical students, and the testing of new surgical methods on experimental individuals. Animal research is typically the required first step towards research involving novel medical treatments and medications meant for human use. As a result, research with animals is essential to biomedical research and must be conducted in order to advance the field.

Concerning the use of animals as study subjects, there are a great number of organizations and people that are committed to ensuring their protection and safety. There are some groups that are working toward the goal of doing away with the use of animals in scientific research. Others believe that doing research on animals is an unfortunate but essential step toward advancing medical knowledge, but they are committed to reducing the amount of needless suffering, pain, and substandard facility conditions that animal subjects are exposed to.

Reviewing research initiatives that include the use of animals is necessary to ensure the protection of animals. These evaluation systems analyze both the hazards and the potential advantages of doing research on animals. This may be problematic for project reviewers and frequently causes for passionate discussions and disagreements regarding the proper use of animal subjects, especially given the animal subjects normally suffer all the dangers while human people enjoy all the advantages. Whether or not animals feel pain in the same manner that people do, whether or not animals experience agony to the same degree that humans do, and whether or not these notions should even play into the discussion at all are all topics that are being discussed and debated.

The government has enacted laws concerning the use of animals in teaching, testing, and research in order to guarantee that research using animals is carried out in an ethical and responsible manner. These regulations also address the care of animals.

Institutions of higher learning and scientific research often make use of a wide variety of animals for a variety of objectives. Others are

investigated within the context of their native environments. There is a huge amount of variety in both the ends to which they are put and the effects that their usage has on the animals themselves. In each and every scenario, it is very necessary that the particular animal be handled in a kind and compassionate way.

Regulation and Administrative Norms

Research and teaching that include the use of animals are only permitted under certain circumstances, including the following:

- To acquire and establish important knowledge that is vital to the comprehension of humans and/or animals;
- For the purpose of preserving and/or enhancing the health and well-being of humans and/or animals;
- To enhance either the management of animals or the production of meat;
- To acquire and compile substantial data that is pertinent to the comprehension, preservation, or enhancement of the natural environment; or
- In order to accomplish the goals set for the educational experience.

Projects that require the use of animals cannot be carried out unless it has first been assessed whether or not they are ethical to do so. This conclusion is obtained by evaluating the potential instructional or scientific value of the research with the effect that it is likely to have on the wellbeing of the animals.

For each and every activity involving animals, researchers and educators are obligated to provide an Animal Ethics Committee with a written proposal. This proposal has to take into account the predicted value of the information that will be obtained, the reason for the project, as well as the ethical and animal welfare considerations taking into mind the 3RS - replacement, reduction, and refinement - as defined in the Australian Code of Practice for the Care and Use of Animals for Scientific Purposes.

In the state of South Australia, adhering to the Australian Code of Practice for the Care and Use of Animals for Scientific Purposes, often known as "the Code," is both required by law and considered to

be obligatory behavior. Infractions of the Code are subject to the penalties that are outlined in the Animal Welfare Act of 1985. The Code was created with the intention of ensuring that the ethical and humane treatment of animals in research and education is maintained at all times. The investigators, instructors, institutions, Animal Ethics Committees (AECs), and all other individuals who are responsible for the care and use of animals for scientific reasons should look to the guiding principles that are outlined in the Code for direction.

The Code emphasises the responsibilities of researchers, educators, and institutions that use living creatures to ensure that animal use is appropriate, that animals' welfare is always taken into account, that alternatives to animal testing are developed, that the number of creatures used is minimised, and that procedures are refined to confirm that animals do not experience pain or distress.

Replacement, reduction, and refinement are the three R's to keep in mind.

The tenets of this view are enshrined in the code of practice for the care and use of animals for scientific purposes.

1. Substitution: Methods that can fully or partly substitute the use of animals in scientific research should be actively required out and implemented whenever and wherever this is feasible.

2. Each study shall utilize no more than the minimal number of animals essential to assure the validity of the scientific and statistical findings. It is unacceptable to put into practice the principle of tumbling the number of animals used if doing so would result in more individual animals being subjected to pain and suffering. Scientific and educational activities involving the use of animals may not be repeated unless needed for the objective or design of the activity. The least amount of animals necessary to accomplish the learning goals must be used in instruction activities, and this number cannot be increased above what is necessary. It is important to prevent the overproduction of animals produced for scientific objectives in order to reduce the number of healthy animals that must be sacrificed.

3. Clarification: In order for animals to be used for scientific purposes, it is necessary to take into consideration their behavioral and

genetic traits, as well as their nutritional, microbial, and overall health conditions. The design and management of animal housing should take into account the particular requirements of individual species. In situations in which this cannot be done because of the requirements of the project, special consideration is required. Transport, housing, feeding, watering, handling, and use of animals should all be carried out in accordance with the requirements unique to each species.

When providing care for the animals, the primary concern must be for the animals' well-being, and the care given should be based on both the animals' behavioral and their biological requirements. It is unethical to remove wild animals from their natural habitats unless they have been bred.

Projects should be developed to prevent both pain and discomfort in animals. In the event that this cannot be accomplished, any discomfort or anguish must be kept to a minimum. Because it is difficult to determine whether or not an animal is experiencing pain or suffering, researchers and educators are required to operate on the assumption that animals go through these sensations in a way comparable to that of people, unless there is evidence to the contrary. This premise must serve as the foundation for all choices pertaining to the well-being of the animals. It is imperative that any animal exhibiting indicators of pain or distress that were not anticipated in the proposal receives early relief from that pain or distress. The relief of this kind of suffering or grief has to take priority over the completion of the project. In the event that this cannot be accomplished, the animal must be put down as soon as possible.

Activities in the fields of science and education that have the potential to cause pain or distress of a kind or degree for which anesthesia would typically be used in medical or veterinary practice must be carried out utilizing anesthesia that is suitable for both the species and the procedure in question. There must be provision made for pain management that is suitable for the animal in question, the procedure in question, and the circumstances. The use of local or general anesthetics, analgesics, or tranquilizing agents must be suitable for the species in question, and at the very least, it should be comparable to how these medications are currently employed in the

field of human or veterinary medicine. In the event that it is determined that the aim of the project precludes the use of anesthetic or analgesic agents to alleviate pain, the planned endpoint of the project must be as early as is practically possible in order to prevent or reduce the amount of pain or distress experienced by the animals. It is not permissible to employ neuromuscular blocking medications in the absence of proper general anesthesia, with the exception of animals in whom all sensory awareness has been removed. If such agents are used, it is essential to monitor the paralyzed animals in a continuous or frequent manner to ensure that the level of anesthesia is sufficient to prevent the animals from experiencing any pain or distress. Avoiding death as a destination whenever it's at all feasible is a necessary. Scientific and educational activities involving the use of animals shall be of minimal duration commensurate with the aims of the project.

CONCERNING ETHICAL PROBLEMS Involved in Agricultural Research

1. Sustainability: Ethical conundrums occur when solutions to issues in the short term are prioritized above those in the long term. In order for institutions to be able to solve long-term challenges, they need a different form of reinforcement than they would normally get. When particular sectors, segments, social classes, or seasons are favored over others when picking issues, finding them, fixing them, or distributing the answers discovered, an ethical challenge might also develop. Concerns that cut across different species and sectors also have an impact on the long-term viability of the results. Not all of the local customs and traditions need to be preserved. Sustainability requires an understanding of both continuity and discontinuity in equal measure (that is innovations or fundamental change in values).

2. Analysis of the ecological health system Scientists not only engage in a process of trade-off but also exercise a form of value judgement when they are aware of the elements that contribute to the environmental system's but continue to produce technologies that undermine it. It might be unethical and fiscally irresponsible to place the burden of short-term compromises on people who would feel their effects over a longer time frame. If the potential or actual long-term

consequences of using a certain chemical input are recognised, but that input is nonetheless used, the eco system will suffer. Applying or not applying the precautionary principle, transferring technologies to countries that might or might not have the ability to analyze the repercussions of their use, and allowing the use of chemicals that are censored in developed countries are all examples of situations that require making value judgments.

3. Acceptance: Not everyone's worries are of equal weight in any given circumstance. Michael Lipton once pointed out the inherent biases that exist in favour of intriguing pests rather than the ones that are pertinent to the topic. When problems exist for millennia without being addressed, it must say something about the values of the society as a whole that such problems don't pose a moral dilemma or make people feel uneasy. The stove, used by millions of women every day, is a great illustration of this point. Transplanting paddy while keeping one's feet submerged is another activity that may cause fungal infections and other health issues, as does carrying water pots on one's head for long distances or carrying grass or twigs on one's head on the slopes of hills by women.

4. Responsibility It is uncommon for researchers to communicate their conclusions to the individuals who provided them with the data they collected. In addition to that Quite often, they do not even bother to calibrate their criteria of relevant or not so relevant research by include the consumers of research in the calibration process. Another situation that gives rise to an ethical conundrum is when a huge multinational firm informs the customers who buy its chemical inputs about a desired resource use technique that is common in the west but is not common in developing nations. It is necessary for the community of companies to have its own code of conduct that prohibits behavior of this kind.

5. The development of capabilities: Any community that must contend with the risk and uncertainty that is inherent in the management of agricultural resources must learn to develop the capabilities not only to predict but also to solve issues that may arise in the future. Therefore, the education and training of young brains becomes an extremely crucial factor in determining the ability to deal

with rising issues in the future. An ethical decision has been made when it is determined that the educational system does or does not include content or pedagogical means that make a potential leader aware of the challenges facing their organization. Values are already communicated when particular crops and/or other agricultural products are depicted in the school curriculum as being purposely inferior on cultural grounds rather than on nutritional grounds or other scientific reasons. This occurs more often than the reverse. A lack of periodic review of the skills that are being developed to address such concerns as externality, diversity, inter sectoral linkages, etc., invariably involves making trade-offs about what should be told to young people and what should be left up to them to learn on their own.

6. The specificity of the location It is common knowledge that the agroecological environment in regions that are rainfed is significantly more diverse. In addition to the technical challenges, developing technologies that would only spread within a limited area presents institutions with a unique set of problems to solve. Incentives for organizations are often offered, and their value is proportional to the spread or prospective reach of a solution. If a technology is addressing problems of small community, it may not invoke a significant encouragement or incentive. As a consequence of this, either the issues in question are not addressed or the individuals who do solve them are pushed to the margins of society. In either situation ethical judgements have to be made by the decision makers. When the research infrastructure, allocation of human resources, and research priorities are weighted more heavily toward communities and regions that have a greater abundance of resources, the ethics of ignoring the communities and regions that are bypassed need to be made clear. It is possible that judgments have been made when hand tools are given less attention than technologies that require a lot of energy.

7. An imbalance between the rights and duties of knowledge holders Neither established nor emerging nations' agricultural research councils have ever mandated that the imbalance of power between formal and informal sectors' knowledge holders be rectified. Those who take part in community-based research projects are seldom thanked, rarely shown the results to which they contributed data, and

almost never offered a cut of the profits made from applying or commercializing the insights their respondents or they themselves gave.

8. Empowerment of informal innovators and holders of information It should come as no surprise that inventiveness may be found in both formal and informal settings. There is no reason why a farmer or an artisan couldn't come up with a novel and inventive solution to a problem in the same way that scientists can. It is quite clear that there is a widespread prejudice towards innovations in the informal sector. The inability of the organized sector of agricultural research and technology to listen to and learn from informal innovators not only deprives the organized sector of ideas from the periphery but also stops it from being motivated by the ideals of many of the grassroots innovators.

The moral choices that must be made in such situations inevitably have an effect on the effectiveness, equality, and excellence of resource and institutional management, as well as the environmental repercussions.

ABOUT THE AUTHORS

Dr. Mohd. Shaikhul Ashraf, Assistant Professor, Department of Botany, HKM Govt. Degree College Bandipora Kashmir, obtained his M.Sc., M.Phil. and Ph.D. from the Aligarh Muslim University, Aligarh. He has also done B.Ed. from the University of Kashmir, Srinagar and M .A. in English from IGNOU, New Delhi. The area of his Research is Plant Pathology and Nematology. He is teaching Botany in various Degree Colleges of Kashmir since 2009. He has published 23 research papers in reputed journals and co- authored five books. He is recipient of several awards and life member of several Scientific and Educational Societies.

Parmar Vishalkumar Rajendrasing
(M.Sc, M.Ed)
Reacher Scholar
Shri Govind Guru University, Godhara (Gujarat)

Dr. Hema Kumari Mehar, Assistant Professor, Ph.D, NET, SLET, Clinical Psychologist. She is assistant Professor in Psychology at UCSSH, Mohanlal Sukhadia University, Udaipur (Raj). She is Master Hypnotist & Practitioner of Self Hypnosis and completed clinical hypnotherapist level –III from California Hypnosis Institute , California USA in 2015. She has presented more than 35 research papers at national and international level and also published more than 12 Research Papers.

Dr. Javad Ghalambor is currently Assistant Professor in the School of Business at Acharya Institute of Management & Sciences (AIMS), Bangalore. He obtained his MBA and a doctorate in Finance from University of Mysore. His areas of interest are quantitative analysis, including statistical analysis, and finance. Besides, he serves as Manager of Research Centre at AIMS.

Dr. S. Kumar working as a Assistant Professor (Teaching Assistant), Department of Disaster Management (Ph.D. in Economics), Alagappa University, Karaikudi, Tamilnadu. He has received the Research Fellowship Bharat Ratna Dr. M.G. Ramachandran Centenary research Fellowship for persuing his Ph.D Research at Manonmaniam Sundaranar University, Tirunelveli. He has experience in teaching 1 year & Research in 3 years. He has published more than 30 articles in reputed journals; more than 30 papers presented in conferences & published 4 patents. He received Best Paper Award, Research Scholar Excellence Award (ICWA), Kalai Rathna Award and Best Assistant Professor Award.

EDITED BOOK FOR
SOCIAL SCIENCE, COMMERCE AND LAW

About the Author

Dr. Kundan Kumar, done the Schooling from St. Michael's High School, Patna, Pursued B.Com (Hons.) in Accounts Vanijya Mahavidyalya, Patna University, Patna, and M.Com. from Patna University, Patna, MBA (Finance) from Lalit Narayan Institute of Economic Development and Social Change, Patna with distinction in 9 papers. Ph.D in Commerce from Patna University, Patna. Qualified UGC NET In Management conducted by UGC and Commerce conducted by NTA. Dr. Kundan worked in two multinational Companies for 6 Years as Senior Finance Executive and presently giving Professional Consultancy to various departments of Govt. of Bihar as well as visiting Faculty in various colleges. He has written 15 research papers out of which 8 are published in UGC approved Journals and 7 in refereed Journals published national and international level. He is author of A Collectively Edited Book in Fields of Law, Politics, and Economics and FINANCIAL MANAGEMENT AND COST ANALYSIS. He also attended Numbers of Nationals and Internationals Seminars, Conferences and workshops related to Management, Commerce and Economics. Dr. Kundan is also Lifetime member of Indian Economic Association as well as Indian Commerce Association.

Ashi is a highly accomplished scholar, holding a B.A. in English Honors from Delhi University, an M.A. in English from the same institution, and a Ph.D. in English from Shri Venkateshwara University. Her academic journey is distinguished by a series of impactful research publications that delve into the realm of Queer studies. Notable contributions include "Understanding Queer: Analysis of Queer Writings in Indian Literature" and "Indian Cinema's Queer Gaze: Portrayal of LGBTQIA+ Narrative on Screen," both published in the International Journal of Research in Social Sciences in January 2021 and May 2021, respectively. Ashi's scholarly pursuits extend to socio-cultural contexts, as evidenced by her work "Exploring Adolescent Sexuality in A Socio-Cultural Context: Abha Dawesar's Babyji" in Shodh Disha (January-March 2022 Volume), and her exploration of mythology and queerness in the works of Devdutt Pattanaik published in the International Journal of Research in Economics and Social Sciences in September 2022. Her recent research on the "Fortrayal of Lesbian Narrative on Indian Screen" in the International Journal of Research in Social Sciences (August 2023) further underscores her commitment to diverse perspectives. Ashi has actively participated in prominent conferences and seminars, such as NCMESS-2017, ICHD-2022 (International Conference), and the National Conference hosted by Shri Venkateshwara University in 2022, showcasing her engagement in academic discourse at both national and international levels.

Contents

1. Issues Faced by Transgenders in India
   Ashi 1
2. How Contemporary Teaching Methods Affect the Learning Process
   Dr. Munmun Sharma 13
3. Evolution of the Tragic Hero in Shakespearean Drama
   Dr. Anupa Sharma 26
4. Privatisation of the Public Sector Enterprises
   Nirmala. R 37
5. The Foreign Policies of India And The United States: A Comparative Study
   Dr. Fakhrul Alom 45
6. An Examination of Factor that Influence Individual Investment Decision
   Dr. Kundan Kumar 55
7. Questionnaire
   Renu Bala 67
8. Investment Straegies and Stock Market Analysis
   Dr Monika Jaroli 88
10. A Comparative Study of Teacher Cybercrime Awareness
    Suman kumar 99
11. A Comparative Study of Folk Drama forms of Rajasthan and Maharashtra with Reference to Raga
    Dr Shiva Vyas 110
12. Parents and Teachers Monitor Cyberbullying
    Anindita Mazumder 123

About the Authors

Prof. Shurveer S. Bhanawat has been working as a Professor and Head, Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur. Sixty eight research articles have been published. He was awarded by ICAI international research award in 2021 and 2022.

Dr. Avinash Panwar is currently working as Associate Professor, Department of Comp. Sc., Course Director, Informatics and Computational Sciences Programme, Nodal Officer College of Engineering and Architecture & Director, Computer Center at Mohanlal Sukhadia University, Udaipur.

Dr. Shilpa Vardia has been working as an Assistant Professor in the Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur. She is the convener of the Master of Finance and Control and Post-Graduation Diploma in Taxation Programme. She has contributed thirty-four research papers and also received ICAI International Research award in 2020.

Dr. Shilpa Lodha is Assistant Professor at Department of Accountancy and Statistics, Mohanlal Sukhadia University, Udaipur (Raj). Her more than 25 research papers have been published in journals of national and international repute. She is Convener of B. Com. Honours.

Dr. Asha Sharma is Assistant Professor in the Department of Accountancy and Business Statistics at Mohanlal Sukhadia University, Udaipur. She is the convener of Bachelor of Vocation and Master of Vocation (Accounting, taxation, and auditing). She has contributed more than 85 research papers.

Dr. Parul Dashora is an Assistant Professor in Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur, [RAJ]. She is also Convener of Certification Programmes of the department. She also has two patents to her credit.

Pushpraj Meena is an Assistant Professor in Department of Accountancy and Business Statistics, University College of Commerce and Management Studies at Mohanlal Sukhadia University, Udaipur (Rajasthan). He has 6 years of experience in practical field of Accounting, Auditing and Taxation.

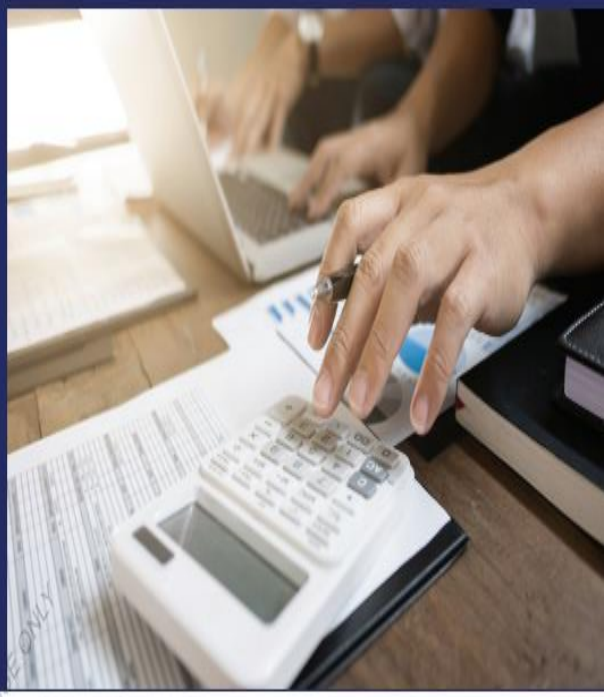
पुस्तक परिचय

आज इस प्रतियोगी युग में हर एक की महत्वाकांक्षाओं को पूरा करना संभव नहीं है। विद्यालय का वातावरण, अध्यापक और माता-पिता की उच्चाकांक्षाएं, विस्तृत पाठ्यक्रम एवं बस्ते के बढ़ते बोझ से विद्यार्थी एवं अभिभावक कई प्रकार की चिंताओं और कुंठाओं से ग्रस्त होने लगता है, जो उसके प्रतिबल को उत्पन्न करता है। इस प्रतिबल का उन पर शारीरिक, भावनात्मक एवं सामाजिक प्रभाव पड़ता है। उपरोक्त सभी बातों पर गौर किया जाए तो वर्तमान पाठ्यक्रम का विद्यार्थियों एवं अभिभावकों पर प्रतिबल सामने आता है। अतः इस विषय पर यह पुस्तक आपके हाथों में प्रस्तुत करते हुए अत्यंत प्रसन्नता हो रही है कि यह हमारा ध्यान इस ओर ले जाने में सहायक होगी। इस पुस्तक में प्राथमिक विद्यालय में पढ़ने वाले विद्यार्थियों एवं उनके अभिभावकों को अपना उत्तरदाता बनाया व प्रतिबल का अध्ययन आरंभ किया, परिणाम आपके समक्ष हैं।

लेखिका परिचय



डॉ. मीना पूर्बिया (B.A., M.A. Geography, B.Ed., M.Ed., NET Geography & NET Education, Ph.D. Education, TET, REET) ने विद्यालय शिक्षा जिला चित्तौड़गढ़ एवं महाविद्यालय शिक्षण उदयपुर शहर में पूर्ण किया। प्राथमिक विद्यालय शिक्षण से कैरियर की शुरुआत करके आपने अकादमिक रुचि के साथ अपना अध्ययन एवं अध्यापन निरंतर जारी रखा। आपने भूगोल एवं शिक्षा स्नातकोत्तर के बाद भूगोल एवं शिक्षा दोनों में नेट उत्तीर्ण किया। आपने अपने साथियों के साथ 'बी.एड. पाठ्यचर्या का संपोषित विकास हेतु शिक्षा विषयक विश्लेषण' विषय पर सीटीई के प्रोजेक्ट पर भी कार्य पूर्ण किया। आपने 'जनजातीय विद्यार्थी की शैक्षिक उपलब्धि पर निर्मितवादी उपागम आधारित अधिगम पैकेज की प्रभावशीलता का अध्ययन' विषय में डॉक्टरेट की उपाधि प्राप्त की। अब तक चार शोध पत्रों का प्रकाशन विभिन्न पत्र-पत्रिकाओं में किया जा चुका है। साथ ही कई राष्ट्रीय एवं अंतर्राष्ट्रीय विषयों पर वर्कशॉप, सेमिनार तथा वेबीनार में भी आपने अपनी भागीदारी सुनिश्चित की है। दो वर्षों के विद्यालय में अध्यापन के बाद पिछले 11 वर्षों से विभिन्न शिक्षक प्रशिक्षण महाविद्यालय में व्याख्याता के पद पर कार्य करने का अनुभव प्राप्त कर वर्तमान में भी अपनी सेवाएं निरंतर दे रही हैं।

The book is about analyzing the financial performance of banks. First Chapter deals with the concept, Importance, significance aspects of banks, and the Banking system. It describes Introduction to the banking industry, Evolution of the banking sector in India, the basic concept behind construction of banks in India, and also deals with the phases of Indian Banking namely: Pre-Nationalization Era, Nationalization Stages, and Post-Liberalization Stages. The second chapter deals with the source of information for the financial performance appraisal of public and private sector banks. and the Journals, Research material, Articles, Reviews for the research work. The aim of the book is to study the impact of various external and internal factors on Financial Performance and to access the level of Financial Performance with reference to stakeholders. The fourth chapter is related to the Research Methodology used for the analysis of data Fifth Chapter deals with the hypothesis testing of the research work and analysis of data through the Kruskal- Wallis Test. The sixth chapter is concerned with the finding and conclusion.

FOR AUTHOR USE ONLY

Asha Sharma
Sonia Chabra

An Analysis of Financial Performance of Scheduled Commercial Banks

In India

Dr. Asha Sharma, is Assistant Professor, Department of Accountancy and statistics at Mohanlal Sukhadia University, Udaipur. Dr. Sharma has a teaching experience of twenty years. She has contributed more than seventy research papers.
Ms. Sonia Chabra is a research scholar of JNV University, Jodhpur.

Tourism has gained importance on account of its economic impacts on the host destination. It provides for support to local economy and provides for ample of employment opportunities as well as helps the region to develop and grow. Tourism nowadays has emerged as a major industry that has economic impacts that are favorable to the host. Efforts are being made to make the industry sounder so as to increase the economic benefits from the same.

The concept of the book is to discover the social or societal effects of tourism industry. It is aimed to find out the social benefit as well as social cost bearded by the host destination, society.

This book concluded that tourism impacts the society in various ways, it has social benefits as well there are social costs being bared up by the society. Tourism has risen as one of the major service industry providing for employment their by improving economy of the state. Tourism has both impacts negative as well as positive of which the latter supersede the ill effects.

The primary objective of this research is to review the cost incurred and social, economic, cultural and overall benefits as enjoyed by the society on account of tourism.

FOR AUTHOR USE

Dr Asha Sharma, is Assistant Professor in department of Accountancy and Business Statistics at Mohanlal Sukhadia University, Udaipur. Dr Sharma has teaching experience of twenty years. She has contributed 75 research papers to reputed international and national journals.
Ms Raksha Bishnoi is research scholar of Jai Narain Vyas University, Jodhpur.

Contents

List of contributors xiii

1. Introduction

Suresh C. Ameta

1.1 Introduction 1
1.1.1 d-d transitions 2
1.2 Deactivation processes 2
1.2.1 Photophyscial deactivation processes 3
1.2.2 Photochemical deactivation processes 4
1.3 Effect of solvent polarity on charge transfer spectra 9
References 13

2. Basic concepts

Rameshwar Ameta

2.1 Introduction 15
2.2 Photochemical aspects 22
2.3 Photoluminescence in coordination compounds 30
2.4 Photochemical processes 34
2.4.1 Photosubstitution reactions 34
2.4.2 Photorearrangement reactions 37
2.4.3 Photoredox reactions 40
2.5 Applications 41
2.5.1 Photochromism 41
2.5.2 Chemical actinometers 42
2.5.3 Release of CO/NO 44
2.5.4 Photoredox catalysis 46
2.5.5 Photochemiluminescence in ruthenium complexes 47
2.5.6 Coordination compounds as triplet quenchers 48
2.5.7 Coordination compounds as sensors 49
2.5.8 Photocatalysis 49
2.5.9 Nano-scale devices and machines 51
References 52

3. Coordination compounds of titanium, zirconium and hafnium

Neetu Shorgar, Priyanka Jhalora, Khushbu Sharma and Shubang Vyas

3.1 Introduction 55
3.2 Coordination compounds of titanium 55
3.3 Coordination compounds of zirconium 61
3.4 Coordination compounds of hafnium 67
References 70

4. Coordination compounds of vanadium, niobium and tantalum

Chetna Ameta, Dharmendra, Yogeshwari Vyas and Purnima Chaubisa

4.1 Introduction 75
4.2 Coordination compounds of vanadium 76
4.3 Coordination compounds of niobium 82
4.4 Coordination compounds of tantalum 85
References 88

5. Coordination compounds of chromium, molybdenum and tungtsen

Saroj Lohar, Dushyant Kumar Prajapati, Jeevan Kunwar Chouhan, Ankita Vijay and Shipra Bhardwaj

5.1 Introduction 91
5.2 Coordination compounds of chromium 92
5.3 Coordination compounds of molybdenum 100
5.4 Coordination compounds of tungsten 106
References 109

6. Coordination compounds of manganese, technetium and rhenium

Monika Jangid, Jayesh P. Bhatt, Mamta Ahuja, Shubang Vyas and Avinash Kumar Rai

6.1 Introduction 115
6.2 Coordination compounds of manganese 115
6.3 Coordination compounds of technetium 123
6.4 Coordination compounds of rehenium 125
References 131

7. Coordination compounds of iron, ruthenium and osmium

Liju Raju and E. Rajkumar

7.1 Introduction 135
7.2 Coordination compounds of iron 136
7.2.1 Electronic structures and photophysics of iron complexes 136
7.2.2 Photochemistry of iron complexes 144
7.3 Coordination compounds of ruthenium 147
7.3.1 Photophysics of $[Ru(NN)_3]^{2+}$ complexes 147
7.4 Coordination compounds of osmium complexes 178
7.4.1 Photoactive oxidation states of osmium complexes 178
7.4.2 Near IR phosphorescent osmium complexes 184
7.4.3 Photophysics of osmium complexes on surfaces 186
7.4.4 Photosensitizers for photodynamic therapy 187
7.4.5 Photochemistry and applications of osmium complexes 188
7.5 Summary 193
References 193

8. Complexes of cobalt, rhodium and iridium

Simran Sharma, Priya Sahni, Rahat Gupta, Anindya Roy and Amlan K. Pal

8.1 Introduction 205
8.2 Luminescent Co(II/III) complexes 206
8.2.1 Photophysical properties of polyhetrocyclic and polypyridyl Co(II/III) complexes 206
8.2.2 Photoredox catalysis of Co(III)-guanidyl complexes 213
8.2.3 Metal-ion sensing by Co(II) complexes 217
8.3 Luminescent Rh(0/I/II/III) complexes 220
8.3.1 Rh(II/III) complexes of acetylacetonato, polypyridylamine, thiolato and macrocyclic ligands 220
8.3.2 Metal-ion sensing by Rh(III) complexes 228
8.3.3 Application of Rh(III) complexes in OLED devices 228
8.4 Luminescent Ir(II/III) complexes 232
8.4.1 Photophysical properties of polypyridyl Ir(III) complexes and their applications in solid-state lighting (OLED and LEC) devices 232
8.4.2 Application of Ir(III) complexes in photoredox catalysis 241
8.4.3 Application of Ir(III) complexes in biological sensing of metal-ion 246
8.5 Conclusion 248
Acknowledgments 248
References 249

9. Coordination compounds of nickel, palladium, and platinum

Athanasios Zarkadoulas and Christiana A. Mitsopoulou

9.1 Introduction 255
9.2 Ligand field photophysics and photochemistry 256
9.2.1 Nickel complexes 256
9.2.2 Palladium and platinum complexes 258
9.3 Charge-transfer photochemistry 259
9.3.1 Diimine and dipyrrin complexes 259
9.4 Bis-dithiolene and diimine-dithiolene complexes 266
9.5 Salen-type complexes 271
9.5.1 Other complexes 276
9.6 Conclusion 286
References 286

10. Coordination complexes of copper, silver and gold

Gustavo A. Álvarez and Esteban Mejía

10.1 Introduction 293
10.2 General considerations 295
10.3 Homoleptic Cu(I) coordination compounds 299
10.4 Heteroleptic Cu(I) coordination compounds 306
10.4.1 Phenanthroline complexes 310
10.4.2 Complexes with pyridyl-type ligands 311
10.4.3 Complexes with N^O, N^P and S^P ligands 312
10.4.4 Complexes with carbene ligands 313
10.4.5 Miscellaneous Cu(I) coordination compounds 316
10.5 The entatic principle and its implication on the photophysical properties of Cu(I) complexes 317
10.6 Silver complexes 322
10.6.1 Homoleptic Ag(I) coordination compounds 322
10.6.2 Heteroleptic Ag(I) coordination compounds 324
10.7 Gold complexes 327
10.7.1 Au(I) coordination compounds 327
10.7.2 Au(III) coordination compounds 330
10.8 Conclusion 332
References 333

11. Coordination compounds of lanthanides

Jean-Claude G. Bünzli

11.1 The elements and their coordination chemistry 341
11.1.1 Lanthanides and rare earths 341
11.1.2 Electronic configuration and oxidation numbers 342
11.1.3 Coordination chemistry 343
11.2 Lanthanide luminescence 345

11.2.1 Energy levels 345
11.2.2 Electronic transitions 349
11.2.3 Sensitization of lanthanide luminescence 358
11.2.4 Quantitative aspects of energy transfer processes 361
11.3 Designing highly luminescent chelates 367
11.3.1 Principles 367
11.3.2 Optimizing energy transfer 367
11.3.3 Minimizing non-radiative deactivation processes 369
11.3.4 Examples of efficient sensitizing systems 376
11.4 Luminescent lanthanide chelates at work 380
11.5 Conclusion 384

Chapter 1

Introduction

Suresh C. Ameta
Department of Chemistry, PAHER University, Udaipur, Rajasthan, India

1.1 Introduction

Photochemistry is well defined as chemistry of excited state of molecules. Excited state has a different electronic state than that of ground state and therefore, it will show a different behavior. The metal complexes are known to have photosensitivity for a long time. The field of photochemistry and photophysics of coordination compound is not new but monumental work of Balzani and Carassitti (1970) gave it a momentum. This field has been excellently reviewed and presented in the form of some reviews, books and proceeding (Adamson et al., 1968; Balzani and Moggi, 1990; Sýkora and Šima, 1990; Horváth and Stevenson, 1993; Kirgan et al., 2007; Balzani and Campagna, 2010; Roundhill, 2013; Chen and Browne, 2018; Glaser and Wenger, 2020; Mensah et al., 2021).

For an effective electronic transition, there must be some interaction between the two: (i) Electric dipole of the molecule and (ii) Electric field vector of the light.

Here, light is absorbed by some species and the probability of absorption is expressed by the Beer–Lambert's law, a well established equation relating various factors.

$$A = \epsilon\, cl = \log \frac{I0}{I} \tag{1.1}$$

Where A = Absorbance (earlier known as optical density), ϵ = Molar extinction coefficient, e = Concentration of substance, l = Path length, I_0 = Intensity of incident light and I = Intensity of transmitted light. A number of electronic transitions are possible in case of coordination compounds and most frequently transitions are:

- d-d transitions and
- Charge transfer (CT) transitions

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00010-1

1.1.1 d-d transitions

The d-d transitions gives weak absorption bands and due to these transitions, most of the d-block metal complexes display colors in solution with low intensity; however, vacant (d^0) and filled orbitals (d^{10}) are exceptions to it. Presence of such low intensity of colors indicates that probability of d-d transition is low.

The color in solutions of these transition metal complexes depends on three factors.

- Metal,
- Oxidation state of that metal, and
- Number of d-electrons (metal)

For example, iron (II) complexes are normally green in color, while iron (III) complexes are either brown/orange in color.

1.1.1.1 The laporte selection rule

The probability of undergoing d-d transitions are decided by the Laporte selection rule. These are as follows

- Laporte selection rule: $\Delta l = +1$
- If there is a change in parity (s $\rightarrow$ p and p $\rightarrow$ d), then these are Laporte allowed transitions.
- If there is no change in parity (p $\rightarrow$ p and d $\rightarrow$ d), then these are Laporte forbidden transitions.

1.2 Deactivation processes

The electronically excited states of coordination compounds (ML^*) can be deactivated in different pathways. Some of them are:

- ML + Heat
- Energy transfer; $ML + Q^*$
- Physical quenching; ML + Q + Heat
- Ionization; $ML^+ + e^-$
- Chemical reaction products of ML
- Chemical reaction products of ML and Q
- ML + hv (Luminesceene)
- Radiationless transfer

The quantum yield of any particular primary process gives the efficiency of total process (Fig. 1.1).

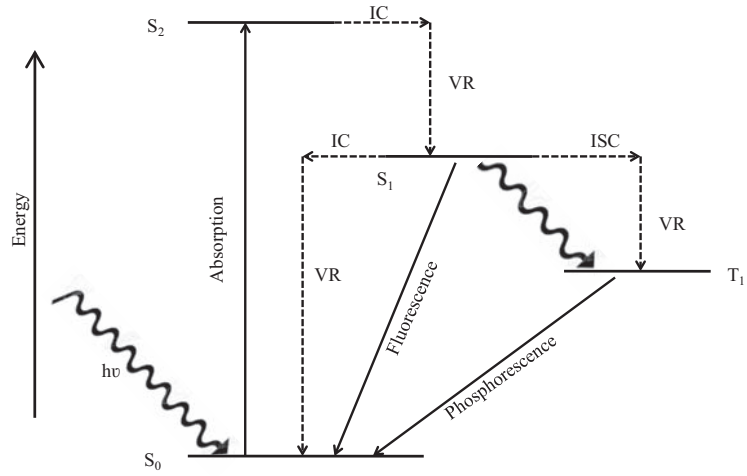

FIG. 1.1 Jablonski diagram.

$$\varphi = \frac{\text{Number of molecules undergoing that process}}{\text{Number of photons absorbed by reactant}} \tag{1.2}$$

Now the excited state can undergo various deactivation pathways:

(i) Photophysical deactivation processes, and

(ii) Photochemical deactivation processes

1.2.1 Photophyscial deactivation processes

First of all, a light of suitable wavelength/frequency is absorbed by some species, which is excited to higher singlet states (S_1, S_2, …) from ground state (S_0). Then there are many possibilities:

This species reverts back to its original ground state with a radiative process and it is called fluorescence. The wavelength of these radiations are same as that of absorbed and it is a rapid process and gives fluorescence immediately. Fluroscence stops, as soon as source of light is removed.

- This excited species (if in higher state like S_2) may undergo internal conversion (IC) to vibrationally excited state of lower excited state S_1, which relaxes in its ground state through vibrational relaxation (VR) by releasing heat.
- If the excited state is S_1, then it can undergo intersystem crossing (ISC) to vibrationally excited state of T_1 (triplet state), which relaxes through vibrational relaxation liberating heat.

- This triplet state T_1 can undergo radiative process, known as phosphorescence. The wavelength of this process is more than the wavelength of light absorbed and it continues even after removing the source of light as it is a slow process.

1.2.2 Photochemical deactivation processes

Excited states have different molecular structures and thermodynamic properties than the ground state. Such as excited state may make use of its excess energy and undergo reactions, which are not normally possible with the ground state molecules. The process of excitation can be associated with some angular and radial distortions, which may promote cleavage of bond.

- **Photoredox addition and elimination processes**

The redox properties of the excited state are different than the ground state. The activated complex may undergo photoredox elimination along with addition reactions. In such cases, a change is there in the oxidation state of the central metal ion accompanied by a change in the coordination number of the complexes. Generally, the obtained products are transient species, which may undergo further secondary (thermal) reactions to give the final products. Photoaddition reactions are normally attributed to an increase in the Lewis acidity of the metal upon excitation.

$$[PtCl_2(bpy)_2] \xrightarrow[Cl^-]{h\nu} [PtCl_4(bpy)_2]$$

Here, oxidation state of platinum(II) is increased to platinum(IV) and the coordination number of the complex is increased from four to six.

- **Intramolecular redox processes**

Redox processes are also possible through an intramolecular pathway, where an electron is exchanged (formally) between a coordinated ligand and the central metal atom. The primary products (reduced metal center and an oxidized ligand), are very reactive and as a result, they may undergo secondary thermal reactions.

$$[CuCl_4]^{2-} \xrightarrow{h\nu} [CuCl_3]^{2-} + {}^{\bullet}Cl$$

$${}^{\bullet}Cl + {}^{\bullet}Cl \xrightarrow{h\nu} Cl_2$$

Here, copper is present in Cu(II) state in the complex $[CuCl_4]^{2-}$, which will be reduced to Cu(I) state in $[CuCl_3]^{2-}$, and chlorine radicals are generated, which as dimerize to yield chlorine.

- **Photochemical isomerization reactions**

Different types of isomerization reactions are there such as optical isomerization, geometrical isomerization, transformations between linkage isomers, tautomerizations, etc. These processes are normally mediated by transients species, which are formed via inner-sphere redox pathways.

$$[Co(NH_3)_5(NO_2)]^{2+} \xrightarrow{hv} [Co(NH_3)_5(ONO)]^{2+}$$

Here, the NO_2 ligand changes its linkage from N (NO_2) to O (ONO)

- **Photosubstitution reactions**

Photosubstitution reactions involve exchange of ligands between the primary and secondary coordination spheres, where oxidation state of the metal ions and its coordination number are retained.

$$[Co(CN)_6]^{n-} + H_2O \xrightarrow{hv} [Co(CN)_5(H_2O)]^{2-} + CN^-$$

$$[Co(CN)_5X]^{n-} + SCN^- \xrightarrow{hv} [Co(CN)_5(SCN)]^{3-} + [Co(CN)_5(NCS)]^{3-}$$

Most common photosubstitution reaction is aquation, where some ligand is being replaced by water in aqueous solutions.

$$[Cr(NH_3)_6]^{3+} + H_2O \xrightarrow{hv} [Cr(NH_3)_5(H_2O)]^{3+} + NH_3$$

$$[Fe(CN)_5NO]^{2-} + H_2O \xrightarrow[H_2O]{hv} [Fe(CN)_5(H_2O)]^{3-} + NO^+$$

- **Photorecemization reactions**

Some complexes may undergo change in its optical isomer from d- to l- or l- to d- in presence of light. In some cases, the reaction is reversible and the product is a racemic mixture of d- and l-forms of the complex.

$$d - [Cr(L-L)_3]^{3+} \overset{nv}{\rightleftarrows} l - [Cr(L-L)_3]^{3+}$$

Tris-complexes of chromium (III) can usually be separated into d- and or l-isomers as these are kinetically inert, but in presence of light, they undergo racemization reactions, as the photochemical reaction is reversible. Here, two probable mechanisms are possible:

(i). 'Twist' mechanism, where a pseudo−rotation causes racemization without affecting the coordination sphere of the central metal ion, and

(ii). 'Bond rupture' mechanism, when a bond is broken and racemization is there, before or during bond is formed again.

- **Photoanation reactions**

In such reactions, a neutral ligand is replaced by an anionic ligand.

$$[Cr(H_2O)]^{3+} + CI^- \xrightarrow{hv} [Cr(H_2O)Cl]^{2+} + H_2O$$

When an aqueous solution of Cr(III) was exposed to light in presence of some anionic ligand such as Cl^-, SCN^-, etc., then a water molecule is replaced by this anionic ligand.

Mehta et al. (2003) made use of photoaquation followed by photoanation reaction of sodium nitroprusside, where first water replaces nitrosylium ligand (a cationic ligand) and then this water is substituted by some sulfur containing ligands. The formation of new complex can be monitored spectrophotometrically and this thio-ligand can be estimated quantitatively.

- **Photochemical isomerization reactions**

Some complex may also undergo isomerization reaction in presence of light from its cis-to transform or vise-versa. Here, cis-form of chromium complex is converted to its transform in presence of light; however, it is also accomplained by some photoanation reaction.

When the complex cis-$[CoCl_2(en)_2]^+$ is irradiated in methanol solution, then the charge transfer band resulted in isomerization to trans-$[CoCl_2(en)_2]^+$ form.

$$\text{cis} - [CoCl_2(en)_2]^+ \overset{hv}{\rightleftarrows} \text{trans} - [Co\,Cl_2(en)_2]^+$$

One of the example of photoinduced linkage isomerization is of cobalt(III) ammine complexes, where exchange of ligand SCN^-- NCS- takes place. It is generally there, when one of the ligands is ambidentate (NCS^-/SCN^- to NO^{2-}/ONO^-).

$$[Co(NH_3)_5SCN]^+ \xrightarrow{hv} [Co(NH_3)_5NCS]^+$$

Such photoisomerization reactions are proposed to proceed through a pathway, where thermally equilibrated excited state is formed on irradiation. This excited state dissociates in the radical pair. For the thiocyanate complex as the photoisomerization reaction of $[Co(NH_3)_5SCN]^{2+}$ to $[Co(NH_3)_5NCS]^{2+}$ does not present in photoisomer to $[Co(NH_3)_5SCN]^{2+}$

$$[Co(NH_3)_5X]^{2+\cdot} \xrightarrow{hv} Co(NH_3)_5{}^{2+}____X^{\cdot}$$

1.2.2.1 Charge transfer bands

Here, question arises that if color is dependent only on d-d transitions, then why some transition metal complexes are intensely colored in solution? In

such cases, there is some change in electron distribution between the metal and the ligand in transition metal complexes giving rise to charge transfer (CT) bands. CT absorptions in the UV/Vis region are intense. The high intensity of the color ($\mathcal{E} > 50{,}000$ L mol^{-1} cm^{-1} or greater) is attributed to high probability of such transitions. It is the case, when these transition are allowed, but as d-d transitions are forbidden, low intensity of color is there. Here, transition are forbidden by selection rule and hence, it resulted in weak absorptions ($\mathcal{E} > 20$ L mol^{-1} cm^{-1}) (Brisdon, 1998).

The CT bands can be easily identified, as these are:

- Very intense with a large extinction coefficient (ε),
- Normally broad, and
- Very strong absorptions even with dilute solutions.

Charge transfer bands of transition metal complexes are due to shift of charge density between molecular orbitals (MOs), which are predominantly metal or ligand in character.

There are generally four types of charge transfer bands such as:

- Ligand-to-metal charge transfer (LMCT),
- Metal-to-ligand charge transfer (MLCT)
- Ligand-to-ligand charge transfer (LLCT), and
- Intraligand charge-transfer (ILCT)
- **Ligand-to-metal charge transfer (LMCT) bands**

Ligands possess bonding (σ and π), antibonding (σ*, π*), and nonbonding (n) molecular orbitals. If the molecular orbitals of any ligand are full, then there is a possibility of charge transfer from the molecular orbitals of ligand to metal d-orbitals (either empty or partially filled). If the transfer is there from the molecular orbital with ligand-like character to the metal-like one, then such transition is called a ligand-to-metal charge-transfer (LMCT).

The absorptions that arise from in this process are called ligand-to-metal charge-transfer bands (LMCT). These LMCT transitions give intense bands, although forbidden d-d transitions may be there, but with weak absorptions. Any such charge transfer from ligand-to-metal resulted in the reduction of the metal (lower oxidation state of the metal). There is grater probability of LMCT transitions, if coordination compounds have π-acceptor ligands. Such LMCT is presented in Fig. 1.2, taking A case of octahedral complex, where metal has d^6 configuration and ligand has filled d-orbital.

Example of these type of complexes include $[Cr(NH_3)_6]^{3+}$, $[Cr(Cl)(NH_3)_5]^{2+}$, etc. An intermediate is formed in the reaction between $[Co(CN)_5]^{3-}$ and $[Fe(CN)_6]^{3-}$, where one cyanide ligand formed a bridge between these two complexes and electron transfer is there

$$[Fe\ (CN)_5{-}C{\equiv}N{-}CO(CN)_5]$$

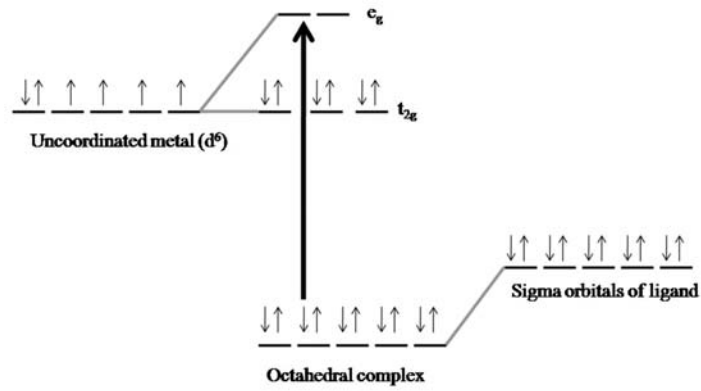

FIG. 1.2 Ligand-to-metal charge transfer (LMCT) in octahedral complex (d^6 state).

- **Metal-to-Ligand Charge Transfer (MLCT) Bands**

On the contrary, if a metal is present in its lower oxidation state (electron rich in nature) and there are low-lying empty orbitals in the ligand; then also there may be a transition, but it is in the reverse direction i.e. metal-to-ligand and therefore, these are called metal-to-ligand charge transfer (MLCT) transitions. Electrons present in the metal orbitals are excited to ligand π^* orbitals on absorption of light. Such metal-to-ligand charge transfer may occur resulting in intense bands. Here also, some forbidden d−d transitions may also be there, but with weak intensity. These MLCT transitions resulted in an increase in oxidation state of the metal as electrons are transferred to ligand. Such MLCT transfer is represented in octahedral complex, where metal has d^5 configuration and vacant π^* orbitals are there in ligand (Fig. 1.3).

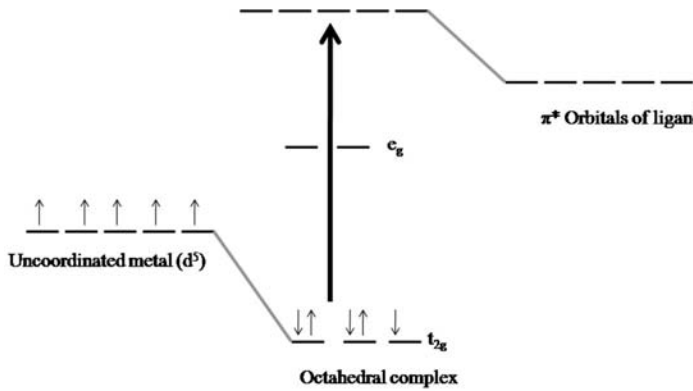

FIG. 1.3 Metal-to-ligand charge transfer (MLCT) in octahedral complex (d^5 state).

In Cu(I) complex of 2,9-dimethyl-1,10-phenanthroline, the copper ion changes its oxidation state as Cu(II) through metal-to-ligand charge transfer upon absorption of light (Iwamura et al., 2007). Complexes with ligands having empty orbitals prefer to undergo MLCT transfer and ligands in this category include CN^-, carbon monoxide, SCN^-, pyrazine, pyridine, bipyridine, o-phenanthroline, dithiolene, dithiocarbamate, etc. Some example of complexes showing MLCT transition are $[Fe(CO)_3(bipy)]$, $[W(CO)_4(phen)]$ $[Ru(bipy)_3]$,$^{2+}$ etc.

- **Ligand-to-ligand charge transfer (LLCT) bands**

Ligand-to-ligand charge transfer (LLCT) is defined as an electronic transition of a metal complex that corresponds to excitation populating an electronic state in which considerable electron transfer between two ligands has occurred.

If a reducing and an oxidizing ligand both are present in same coordination compounds, then there is possibility of low-energy LLCT transitions. Vogler and Kunkely (2007) has reviewed such relationship between zwitterions and metal complexes with low-energies LLCT transitions. Here, the zwitterions can also serve as ligands. Han et al. (2007) prepared a series of platinum(II) terpyridyl alkynyl complexes and observed a lowest-energy absorption corresponding to a ligand-to-ligand charge-transfer transition from the acetylide to the terpyridyl ligand. Intraligand charge-transfer (ILCT) transition is also there in complex from the π orbital of the 4′-phenyl group to the π^* orbital of the terpyridyl.

- **Intraligand charge-transfer (ILCT) bands**

It a ligand itself has a chromophore, then there is also a possibility of an absorption band, when an electron is transferred from one part of ligand to its other part, and it is called an intraligand band charge transfer (ILCT).

Larsen et al. (2014) reported the synthesis of donor—acceptor ligands 11-(4-diphenylaminophenyl)dipyrido[3,2-a:2′,3′-c]phenazine (dppz-$PhNPh_2$) and 11-(4-dimethylaminophenyl)dipyrido[3,2-a:2′,3′-c]phenazine (dppz-$PhNMe_2$), and their rhenium complexes $[Re(CO)_3X]$ (where $X = Cl^-$, py, 4-dimethylaminopyridine (dmap)^2). It was reported that optical properties of the ligands and complexes were dominated by intraligand charge-transfer transitions from the amine to the dppz moieties. These ligands show strong emission in organic solvents, which are consistent with the ILCT character exhibiting strong solvatochromic behavior (Fig. 1.4).

1.3 Effect of solvent polarity on charge transfer spectra

The charge transfer spectrum is affected by polarity of solvents, if the complex is an ion pair. As the position of the charge transfer band is considered as a transition energy and therefore, it depends on the solvating ability of the

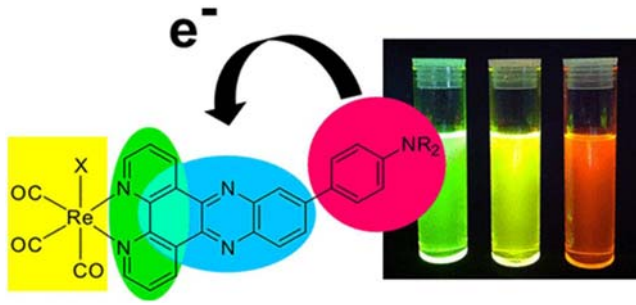

FIG. 1.4 Change of color through intraligand energy transfer. *Adapted from Larsen, C.B., van der Salm, H., Clark, C.A., Elliott, A.B., Fraser, M.G., Horvath, R., et al., 2014. Intraligand charge-transfer excited states in Re(I) complexes with donor-substituted dipyridophenazine ligands. Inorg. Chem. 53 (3), 1339−1354. With permission.*

solvent. It was observed that if the solvent of high solvating ability is there, then there is a shift to lower wavelength (higher frequency) in the position of charge transfer bands.

The dipole moments of solvent molecules (polar) are aligned perpendicularly or maximally with the dipoles of ground or excited state. An interaction will be there, if the ground or excited state is polar, which will lower the energy of the ground or excited state through solvation. The effect of solvent polarity on charge transfer spectra can be understood by following examples.

In total, there are four possibilities and these are:

- **Ground state and excited state; both are neutral**

When the ground and the excited state are both neutral in nature, then no shift will be observed in wavelength. In that case, no change is there. A polar solvent is not able to align its dipole with either ground or excited state, if these are neutral.

- **Ground state is neutral, but excited state is polar**

In some cases, if the ground state is neutral, but excited state is polar, then the solvent will interact only with the excited state. The solvent will align its dipole with the excited state and as a result, its energy is lowered through solvation. Such type of interaction will lower the energy of the polar excited state and as a consequence, wavelength is increased and energy (frequency) is decreased (Fig. 1.5).

- **The ground state and excited state; both are polar**

If the ground state is polar, then the polar solvent will align its dipole moment with the ground state. As a result, maximum interaction will be there and energy of the ground state will be lowered (higher wavelength, and lower frequency or energy). On the other hand, dipole moment of the excited state

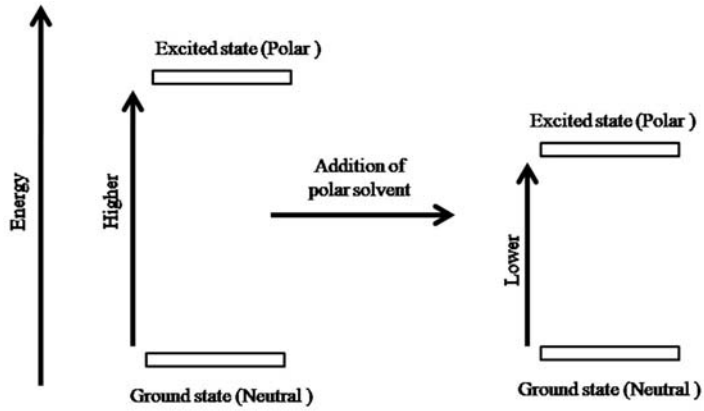

FIG. 1.5 The ground state is neutral, but excited state is polar.

would be perpendicular to the dipole moment of the ground state, because of alignment of dipole moment of polar solvent with the ground state. Such an interaction will increase the energy of the polar excited state (lower wavelength, and higher frequency or energy) (Fig. 1.6).

- **The ground state is polar, but the excited state is neutral**

If the ground state is polar in nature, then polar solvent will align its dipole moment with the ground state. In this case, maximum interaction will be there and the energy of the ground state will be lowered (higher wavelength, and lower frequency or energy). If the excited state is neutral in nature, then no change in energy will be there. A polar solvent will not be able to align its dipole with a neutral excited state. As a result, an increase in energy will be

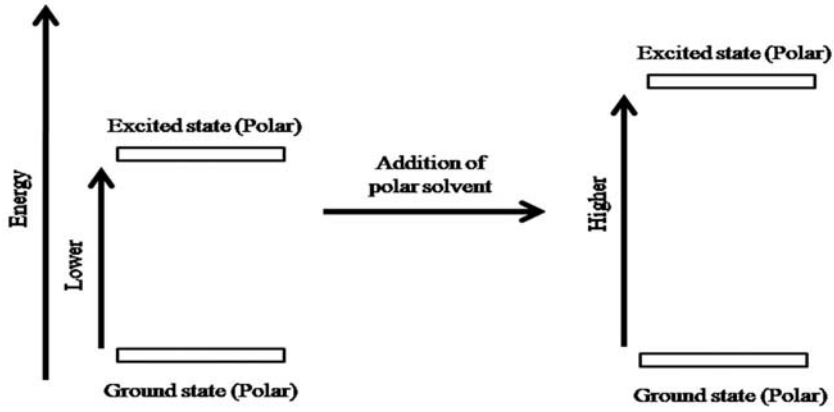

FIG. 1.6 Ground and excited states; both are polar.

observed, because the ground state is lower in energy (lower wavelength, and higher frequency or energy) (Fig. 1.7.).

There are various applications of photochemistry and photophysics of coordination compounds. These include the use of coordination complexes in:

- Solar cells, particularly dye-sensitized solar cells, where these have been used as photosensitizer,
- Actinometry, where these have been used for determining photon flux,
- Photosensors to detect the presence of some specific material in minute quantities,
- Photogeneration of hydrogen from photospliting of water as hydrogen has been predicted as the fuel of future,
- Photoreduction of carbon dioxide to some useful synthetic fuels using these compounds as photocatalysts or photosensitizers even upto the primary stage of mimicking photosynthesis (Artificial photosynthesis), and putting a check an ever increasing amount of carbon dioxide in atmosphere (control of global warming).
- Photochromic devices, where a complex will change its color in presence of light and reverts back to the original color on removing the source of light, and
- Use in photodynamic therapy (PDT) or photochemotherapy (PCT) for treatment of some diseases including dreadful disease like cancer.

Some more applications of photochemistry of coordination compound will emerge in further decades.

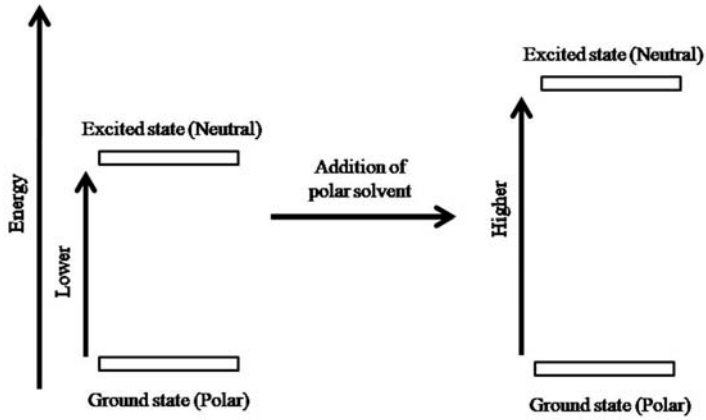

FIG. 1.7 Ground state is polar, but excited states is neutral.

Chapter 2

Basic concepts

Rameshwar Ameta
Department of Chemistry, PAHER University, Udaipur, Rajasthan, India

2.1 Introduction

The photochemistry and photophysics of coordination compounds has been excellently presented by Balzani and Carassitti (1970). Then onwards it has progressed rapidly and this field has been reviewed by several workers from time to time (Balzani and Moggi, 1990; Horváth and Stevenson, 1993; Kirgan et al., 2007; Balzani and Campagna, 2010; Roundhill, 2013; Ford, 2016; Chen and Browne, 2018; Glaser and Wenger, 2020).

The main difference between organic and coordination compounds (metal complexes) lies in their ground state electron configuration. In most of cases, ground state electronic configuration of organic compounds is a closed shell type, and the ground state is a singlet state (S_0). When light is absorbed and an electron is promoted from lower energy (Highest occupied molecular orbital, HOMO) to higher energy (Lowest unoccupied molecular orbital, LUMO) molecular orbitals, singlet and triplet states both are formed in pairs (S_1 T_1), (S_2 T_2), etc. Every triplet state is of lower energy than its corresponding singlet state and it is due to less electron−electron repulsion, when electrons have parallel spins. Hence, in organics, the lower excited state is commonly a triplet state (T_1). But, when metal complexes are taken, the situation is very much different. In many of the cases, the ground state has degeneracy of orbitals and some orbitals are not completely filled and therefore, the ground state has multiplicity higher than one (in accordance with Hund's rule). Another difference observed is the presence of heavy atoms, which are not present in organic molecules, but in complexes, presence of such metal atoms may cause considerable amount of spin−orbit coupling (particularly for metals of second and third transition series). It has been observed that in such cases, spin−forbidden absorption bands are having the same intensities as that of the absorption bonds obtained for spin−allowed transitions. This has been found particularly in platinum complexes. The efficiency of intersystem crossing (ISC) i.e., $S_1 \rightarrow T_1$ for complexes having S_0 ground state is close to 100% and fluorescence quantum yield reaches almost zero.

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00014-9
Copyright © 2023 Elsevier Inc. All rights reserved.

Also, the rate constants of phosphorescence ($T_1 \rightarrow S_0$) and ISC ($S_1 \rightarrow T_1$) for organic compounds are very less than the rate constant of these processes in complexes. This can be seen that the varying extent of spin−orbital coupling causes longer life time to lowest spin−forbidden excited state (1 s) as compared to the life time of lower spin−forbidden excited state of $[Ru(bpy)_3]^{2+}$ (microseconds).

In last 6 decades or so, the field of photochemistry and photophysics of coordination compounds has gone through many steps with increase in complications. The photophysical behavior of simple complexes of simple ligands (ammonia, cyanide, etc.) were investigated in photosubstitution and phototredox decomposition reactions. Earlier studies were also focused on the use of metal complexes in biomolecular process i.e., energy and electron transfer. The Jablonski diagram was the solely guiding about various processes, which was successful in explaining the photochemical and photophysical nature of organic compounds, but there is much difference in the Jablonski diagram for the organic compounds and the coordination compounds. The main reason is the significant difference in the involvement of ligands and metal orbitals. Photodecomposition of organic compounds in singlet states was found quite common but sufficiently good number of coordination compounds were found to be stable toward photodecomposition; however, these are capable of undergoing excited state redox processes, which can be used to convert light energy into chemical energy.

It was also observed that the rate constants for a large number of complexes are inconsistent in the modern theories of kinetics. The field of photo-induced reactions of coordination compounds has reached to a stage now that if supramolecular chemistry and photochemistry are considered, then the constructed systems can easily perform the photo-induced processes. In present scenario, the photoredox reactions of metal complexes are used as essential parts for fabrication of molecular machines, which gets power and other molecular functional devices (light signaling processes) employing bottom-up approach. If one looks at the history of photochemistry, then its first mention was the effect of light on silver chloride and photography (John and Field,1963). It was then followed by sensitivity of metal complexes, particularly $[(Fe(CN)_6)]^{4-}$toward light was observed (Balzani et al., 2008) gradually with the development of the concepts of light absorption and quantum yield, chemical actinometer were developed using Fe^{3+} and UO_2^{2+} complexes.

Later on, quantitative investigation on the photochemical behavior of $[Fe(CN)_6]^{4-}$ and Co(III) amine complexes in aqueous solution provided insight about the mechanism of photochemical reactions involved. At that time, no theoretical framework was available, which can explain the absorption spectra and nature of the excited states of the coordination compounds. Due to this drawback of non-availability of theoretical bases, the mechanism of the photoreaction and luminescence in complexes could not be interpreted. But later on with the development of change transfer (CT) bands in the

absorption spectra of these complexes resulted into the explanation of absorption spectrum of the complexes (Orgel, 1954). After this development the photochemistry of coordination compounds has reached to a state of modern science, but much of the work published was on the Cr(III) complexes and their luminescence. Then scientists focused an Co(III) complexes due to the observation that in these complexes, photochemical behavior changes with the wavelength of light used for excitation.

In late sixties, enormous progress of photochemical and luminescence studies an organic compound was there. Large number of publications in the field of photochemical reactions of organic compounds has put forward some basic photochemical concepts, which were immediately utilized for coordination compounds also. Thereafter, 1965 onwards, the photochemical and photophysical behavior of any species either an organic compound or a charged metal complex can be interpreted on the basis of energy level diagrams, selection rules, electronic configuration and their electronic spectra.

It is necessary to understand various photophysical and photochemical pathways and for this, Jablonski diagram was proposed (Fig. 2.1).

Where S_0 is the singlet ground state and S_1 and T_1 are the lowest singlet and triplet excited states, respectively. Straight arrows are used to indicate radiative transition (photons) and wavy arrows are used to indicate the non-radiative transitions (not involving photons). By using Jablonski diagram, one can explain the mechanism of photochemical reaction. Now a days, the explanation is given in terms of different potential energy surfaces (PESs), which are acquired by a molecule after excitation of light. Different PESs are related to different electronic states, which typically change their electronic character and can cross PESs in different ways.

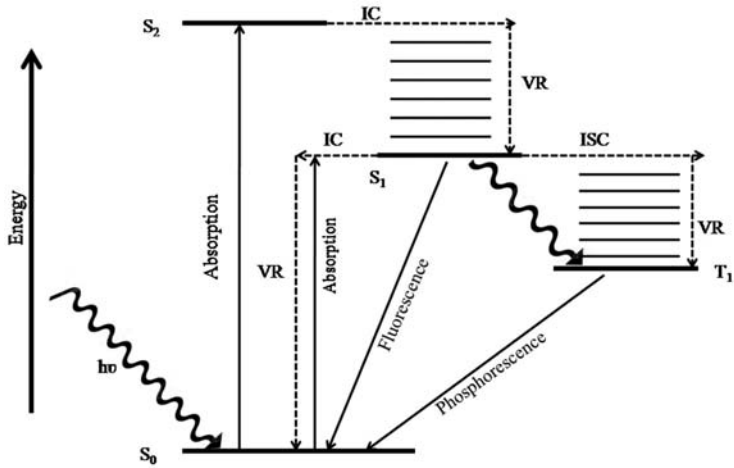

FIG. 2.1 Jablonski diagram.

After the absorption of light, the molecule reaches to an electronic excited state and by this process, a wave packet is generated, which progressed with the time. This is due to the fact that the forces, which are operating on the excited state of the molecule are different from the ground state. In order words, the position of minima of this wave in ground and excited states are different. This motion of molecule from ground to excited state by absorption of photon (hυ) will direct the molecule to be in different geometry in the excited state, than that in the ground state. On the basis of the nature and surface potential of the excited state, the wave packet may be relaxed to a new minimum; thereby, providing long-lived excited state, which finally decays to the ground state via fluorescence (Fl); or continues moving to the other regions of the potential energy surfaces.

There is another possibility also that wave packet may reach to the crossing points after surpassing same potential energy barrier; and hence, the so called non-adiabatic population transfer to other surfaces may occur. In these cases, Born-Oppenhiener approximation is broken down and electric and nuclear motions are coupled. This will push a radioationless process to return to the reactant or a new molecule is formed as a photochemical product. Internal conversion (IC) is a process, in which radiationless transition of molecule takes place between the states of same multiplicity (i.e., S_1 and S_0) and these processes are mediated by crossing points, which are called conical intersections as there is double conical surface around the degeneracy point. This discovery that IC process in mediated by conical intersections, which are ubiquitously present in chemistry and in biology, can also be said as breakthrough in the development of modern theoretical photochemistry.

The intersystem crossing process is mediated by crossing points between states of different multiplicities (i.e., S_1 and T_1), if there is almost no spin-orbit coupling (SOC). It is well known that SOC is highly dependent on the electronic wave function of the two states as well as the nuclear change of atoms, and therefore, the probability of ISC process will be high in those molecules, which contain heavy atoms as compared to pure organic compounds. However, ISC is also possible in molecules with only light atoms. ISC will produce a long-lived state (triplet), which finally goes to ground state via radiative (which is called phosphorescence) or non-radiative transitions or as an alternate, some photochemical transformations take place in this state (triplet) to give rise to the products.

It has been observed that there are many systems, which have additional states, more than two multiplicates or other processes affecting the life time of excited states. It is to be noted that understanding of excited state and its chemistry can be predicted, if knowledge about PESs is sufficiently strong enough. However, PESs processes function of large dimensions in polyatomic molecules and make them difficult to characterize. This type of general computational approaches, namely static and dynamic approaches have been developed to know about PESs. Static approach is well established geometry

optimization method (i.e., minima, transition states, crossing points), which are related to get relaxation routes. The main drawback of this approach is that there may be missing of important geometrics and therefore, the relaxation mechanism will be overlooked. Also, this approach does not give information about time scales and so it can not indicate that which routes are most important and it does not show the quantum yield (ϕ) of the photochemical relation? Complementary to it, there is another approach (dynamic approach), the progress, or the evolution of the coupled nuclear and electrons is directly stimulated. This is also called non-radiative molecular dynamics simulations. This approach is also capable of finding directly the critical geometries, which were really formed by the systems after excitation like a sort of molecular movie. This approach also gives information about time scales, so that the quantum yield can be obtained.

Although the concepts discussed here are simple in the approach, but these methods are greatly hampered by the multidimensional nature of potential energy surfaces and electronic complexity of the system. Also, dynamic simulations cannot be carried out beyond picoseconds and therefore, it puts a limit, above which time scale, the approach cannot be used. So in practice, many problems of balancing computational cost, and accuracy, time scale limitations and dimensionality process various approximation and therefore, for better understanding of the photophysical and photochemical concepts of coordination compounds, one has to return back to the Jablonski diagram for organic molecules.

Molecular systems are many electron systems. Approximate electronic wave functions can be written for molecule in the form of multiplication of one electron wave functions. Each of these function contains two parts i.e., orbital and spin parts. The orbital part of the many electron system defines the electronic configuration. Molecular photochemistry of organic compounds can be also better understood using molecular orbital energy level diagrams and electronic transitions can be expressed from highest occupied molecular orbital (HOMO) to lowest unoccupied molecular orbital (LUMO) and by this transition, the excited state and ground state electronic configuration of the molecule can be expressed. For example in case of formaldehyde, the $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ leads to the electronic configuration $(\pi)^2\,(n)^0\,(\pi^*)^0$ and $(\pi)^0\,(n)^2\,(\pi^*)^0$ excited state configuration. In approximation, every state associated with a specific electronic configuration is considered to be the sum of the energies of the occupied molecular orbitals. To obtain more appropriate description of the energy states of the molecule: (i) Spin functions should be linked to orbital functions and (ii) Interelectronic repulsion must be considered as it was neglected in all earlier discussions. These (i) and (ii) aspects are closely associated with each other and the importance of these points lies in the result that splitting of an electronic configuration into various states can occur. For examples in case of formaldehyde, when spin and electronic repulsion were incorporated, it resulted into the splitting of excited electronic configuration

into a pair of triplet and singlet states. Singlet states are always of higher energy as $e^- - e^-$ repulsion is higher for paired electrons. It has also been observed that the state, which arises due to π - π^* configuration splits more (singlet-triplet splitting) as compared to the state, which arise due to n - π^* configuration.

This effect of splitting of electronic configuration into singlet-triplet states is due to the dependence of the electron-electron repulsion on the quantity of the overlapping of MOs containing the two electrons. The electronic states can also be designated by symmetry species of the point group to which the molecule belongs. For example, in case of formaldehyde (HCHO), which belongs to $C_{2\upsilon}$ symmetry point group, A_1, A_2, etc. can be assigned. The $^1S_0$ state belongs to A_1 symmetry species, where the left superscript denotes the spin multiplicity (which can be calculated by 2 S + 1, where S in total spin of the system under consideration) and it multiplicity can be calculated by adding one into the number of unpaired electrons.

Hence, in case of coordination compound, the old Jablonski diagram will be very less effective to describe various photophysical and photochemical processes involved after absorption of light by metal complexes, but the pathways after absorption may be understood by constructing MOs energy level diagrams and incorporating the spin-spin interaction and $e^- - e^-$ repulsion. The splitting of electronic configuration of the complexes can be viewed as similar to the general lines discussed earlier for organic molecules.

The excited state configuration of the octahedral complex can be obtained by promotion of an electron from occupied MOs to vacant MOs. The various MOs are designated according to their greater contribution of AOs, which means (a) Strongly bonding, predominantly ligand centered σ_L π orbitals, (b) Bonding predominating ligand, (c) Essential non-bonding metal centered π_M orbitals of t_{2g} symmetry, (d) Antibonding, predominating metal centered σ_n^* orbitals of e.g., symmetry (e) Antibonding, predominantly ligand centered π_L^* orbitals, and (f) Strongly antibonding, predominantly metal centered σ_M^* orbitals.

In octahedral complexes of metal ions with d^n, the ground state electronic configuration has completely filled orbitals of the type (a) and (b), whereas n electrons occupy the orbitals of the type (c) and (d). The following electronic transition are expected for octahedral complexes:

(i) Metal-centered transition (MC) form orbitals of type: (c) → (d),
(ii) Ligand-centered transition (LC) from the orbitals of type: (b) → (e),
(iii) Ligand-to-metal change transfer (LMCT) transitions in orbitals of the type: (b) → (d), and
(iv) Metal-to-ligand change transfer (MLCT) transition from the orbitals of the type: (c) → (e)

The order of the relative energies of the excited electronic configuration depends upon the nature of metal and ligands, which can be predicted from the

knowledge of chemistry. When first row transition metals are taken, it is expected that low energy metal centered transition may occur in these cases, while low energy LMCT transitions are predicted, when at least one of the ligand is easy to oxidize and the metal is easy to reduce. However, the low energy MLCT transition are expected in the complexes, in which metal is easy to oxidize and ligand is easy to reduce and low energy LC (ligand centered) transition are expected for aromatic ligands with extended π and π^* orbitals.

In case of coordination compounds, the splitting of electronic configuration into states is more simple as compared to organic compounds as coordination compounds possess high symmetry (i.e., degenerate MOs) and ground configuration (i.e., partially occupied HOMO).

Therefore, in case of coordination compounds, the Jablonski diagram will be more complex and specific as compared to organics. The following points are to be seen:

(i) Another state than singlet and triplet state can appear, but the lowest one will be that state., which has highest multiplicity for each electronic configuration,
(ii) Ground state possesses highest spin multiplicity. Excited states can occur that belong to the same electronic configuration of the ground state and
(iii) A single electronic configuration can give rise to more than one pair of states of different multiplicity.

Therefore, in general discussion of molecular photochemisty, generic Jablonski diagram based on singlet and triplet states will be used.

After the absorption of light, the excited state formed may decay intramolecularly. Theoretically, the transitions between states of same multiplicities and transition between states of different multiplicities are spin allowed and spin-forbidden, respectively. So, in the UV visible spectrum, the molecule shows an absorption based corresponding to $S_o \rightarrow S_n$ transitions.

Metal complexes are generally having high degree of symmetry, and therefore, selection rules based on symmetry also play an important role in determining the intensity of the absorption bands. However, the spin conservation condition is relaxed, when a heavy atom (the metal) is present.

As the excited states are unstable and they can decay not only through dissociation or iomerization (intramolecular reaction), but also very often through intramolecular radiative and non-radiative relaxations also. The electronically exited molecule in upper spin allowed excited states normally acquires fast and 100% efficient radiationless (shown by wavy arrow) deactivation (IC) to the lowest spin-allowed excited state (S_1). Other than intramolecular photochemical processes, the excited state in S_1 has three process (first order) to exercise for its deactivation:

(i) Non-radiative decay to ground state, $S_1 \rightarrow S_0$ (IC) Rate constant (k_{IC})
(ii) Radiactive deactivation $S_1 \rightarrow S_0$ Rate constant (k_{Fl})

(iii) Intersystem crossing (ISC) to the lowest triplet state (T_1) rate constant (k_{ISC}) and after reaching T_1, it can undergo deactivation through non-radiative intersystem crossing (k'_{ISC}) or radiative (phosphorescence, k_{Ph}) decay to S_0. In case of metal complexes, the usually forbidden process, namely intersystem crossing (ISC) and phosphorescence processes became faster due to presence of heavy atom (metal itself). The lifetime (τ) of an excited state is the time needed to reduce the exited state concentration and it is given by the reciprocal of the summation of the deactivation rate constants. It can be expressed as:

$$\tau(s_1) = \frac{1}{k_{IC} + k_{F1} + k_{ISC}} \tag{2.1}$$

$$\tau(T_1) = \frac{1}{k'_{ISC} + k_{Phosp.}} \tag{2.2}$$

The lifetimes of the lowest spin allowed and spin forbidden excited states τ (S_1) and τ (T_1) are approximately 10^{-9}–10^{-7} and 10^{-3} –10 degrees, respectively for organics, but for metal complexes, these lifetimes are even more shorter. The lifetime of the lowest spin forbidden excited state of naphthalene is about 2 s, while that of $[Ru(bpy)_3]^{2+}$ is about 1 μs (as Ru ion is a heavy atom).

The fluorescence and phosphorescence quantum yields (Φ) are known for various metal complexes and these can be expressed as:

$$\Phi_{Fe} = \frac{K_{F1}}{k_{IC} + k_{F1} + k_{ISC}} \tag{2.3}$$

$$\Phi_{phosp.} = \frac{K_{Phosp.} \times k_{ISC}}{\left(k'_{ISC} + k_{Phosp.}\right) \times \left(k_{IC} + k_{F1} + k_{ISC}\right)} \tag{2.4}$$

The knowledge of lifetimes of excited state and quantum yields of fluorescence and phosphorescence are helpful in understanding the mechanism of various photochemical reactions of coordination compounds.

2.2 Photochemical aspects

In the early half of seventies, a number of publications appeared about the bimolecular processes involving metal complexes, where main focus was on the ligand substitution reactions, photoredox decompositions and photoionoization reactions. However, biomolecular processes were not investigated at any level. This situation drastically changed, when researchers started working on limitations of coordination compounds and the discovery that the lowest excited state of the various complexes of Cr(III), Ru(II), Os(II), etc. showed a sufficiently longer lifetime in fluid solution, so that these are able to

participate as a reactant in biomolecular reactions. More advantageous is the fact that Ru(II) and Os(II) bipyridyl type complexes can undergo reversible redox reactions; in ground as well as excited states and, therefore, they were used as reactants and also as a mediator in light induced and light generating electron transfer processes. The photochemical transformations for solving various energy problems have attracted the attention of scientific community and much work was carried out after the energy crisis in the early 1970s. The particular interest was focused on water splitting and it was understood that $[Ru(bpy)_3]^{2+}$ and related coordination compounds can function as photocatalysts for such a process.

The main revolution in the field of photochemistry of coordination compounds was observed in the period 1975−85. The properties of a molecule (compound) in excited state is quite different from properties in ground state. Because of high energy content, an excited state is both; a stronger reducing species as well as a strong oxidizing species than the corresponding ground state. Therefore, redox potential of the excited and ground states played an important role to understand the use of photoexcited species for various applications. It can be shown from kinetics that excited states ($>10^{-9}$s) may possess a chance to be involved in encounters with other solute molecules. Generally, only the lowest excited state fulfill this condition in metal complexes with longer lifetime and therefore, the coordination compounds in their lowest photoexcited states have number of interesting properties, which can be used in harnessing solar energy, photosplitting of water, photoreduction of CO_2 (the main culprit of the global warming), etc.

Introduction of superamolecular photochemistry added another photochemical aspect, which gained a lot of attraction in late 1980s. This field is an interdisciplinary subject in nature in true sense and it is based on concepts like molecular recognition, organization, and self-assembly. In supramolecular chemistry, focus is changed from molecular photochemistry of metal complexes to molecular assemblies or multicomponent systems. Various light powered devices and molecular machines can be designed using supramolecular photochemistry. Here, preorganization is very important because that favors energy and electron-transfer processes.

The chemical reactivity of the transition metal complexes can be understood on the basis of the d-electron configuration of central atom. The kinetic inertness of $(t_{2g})^6$ octahedral complexes is attributed to the rearrangement of the ground state of octahedral structure to any transition state will certainly require a large activation energy.

But, the reactivity in the excited state will be different due to change in the electron distribution (as compared to ground state). It can be seen that in the MO energy level diagram for an octahedral complex that in $\pi\ (t_{2g}) \rightarrow \sigma_{M*}\ (e_g)$ transition in octahedral complexes, the charge distribution between metal and ligand remains almost unchanged due to metal−centered (MC) character of these transitions. Therefore, the ground state is generally stable toward

intramolecular redox processes (homolytic cleavage of M−L bonds), and the MC excited state tends to remain stable toward redox decomposition of the complexes. The σ_{M*} (e.g.,) orbitals are greatly σ−antibonding, and hence, presence of any electron in these σ* orbitals will make some M−L bonds weak, which will facilitate a ligand substitution reaction. The entering of new ligand in facilitated by the presence of empty π_M (t_{2g}) orbital for bond formation.

In case of charge transfer excited state, which are produced by the transition from MOs basically localized on the ligand to localized on the metal (LMCT, ligand−to−metal charge transfer). These transitions create a radical distribution of the electronic charge between central metal and ligands, which will cause change in the oxidation state of metal (or oxidation of ligand and reduction of metal). Therefore, CT excited state will tend to produce intramolecular redox processes, resulting in the reduction of the ligand and oxidation of metal or vice versa. It can be seen that due a CT process, the oxidation state of metal changes and consequently an inert complexes may become labile and as a result, the complex may undergo decomposition. It can be observed that LMCT transition in Co(III) complex changed it to Co(II) complex, which will become kinetically labile due to the presence of an electron in the σ_{M*} (e.g.,) orbital and therefore, it is assumed thar all legands will leave the coordinate shape, whether or not their involvement is there in CT transition? It is to be emphasized that MLCT transition increases the positive charge on the metal, which will facilitate a nucleophilic attack by outer ligands. The CT transition may also affect the acid strength of the complexes having protic ligands (NH_3, H_2O, etc).

Intermolecular CT transitions undergo redox process, which give a reduced form of a complex and if it is not stable, it will decompose. However, any redox process to take place actually, it depends on the intrinsic properties of the ion pair and environment. In the same way, charge−transfer−to−solvent transition (CTTS) may result into an oxidized form of the complex and a solvated electron.

When an electron transition takes place between two MOs, the ligand centered (LC) or intraligand excited states are formed, which are almost localized on the ligand. Since, there are many varieties of ligands, the reactivity of LC excited state cannot be predicted with certainity. However, as a first approximation, neither the charge transfer distribution between metal and ligand is changed nor the bonding structure of the complexes due to LC transition. But due to change in the electronic structure of the ligand, change in various important parameters will be there such as its donor and acceptor properties, dipole moment, acid strength, equilibrium geometry, etc. These changes may affect the stability of the complexes.

Till now, the conceptual framework for the photochemical and photophysics processes of complexes have been discussed, but there cannot be any rule formulation for the photoreactivity i.e., which type of photoreaction will

occur, because the nature of the electrically excited states is yet to be fully understood? As mentioned earlier, the excited states directly formed by irradiation can undergo radiationless deactivation processes before getting a chance for reaction and therefore, the lower excited states may be produced, which are different in nature from the original state, e.g., an excited state of MC can be formed by deactivation of CT state. It is clear that the type of reaction (redox, substitution, etc.) depends on the nature of the excited state, in which the reaction is taking place. When ligand substitution and redox reaction are taking place, one cannot be certain that these reactions are the results of the CT or ligand filled nature of the excited state. In reality, the photophysics and photochemical behavior of the complex is caused by a complicated adjustment between inherent chemical reactions, radiative and nonradiative deactivation processes of the electronic states.

In case of solution photochemistry of complex ions, the pertinent question arises that which particular excited state is formed? The answer can be given on the basis of MO energy level diagram of the complex and one can develop qualitative view of expected reaction pathways. Earlier, mechanism of the photochemical reaction were largely proposed on the basis of reaction products and quantum yield of the reaction; thus, making a comparison of their data with electronic and spectroscopic properties, but with the advent of density functional theory (DFT) and laser flash photolysis, the scenario of knowing the mechanism of the photochemical reaction of complexes has drastically changed.

In short, the conceptual basis of photophysical and photochemical processes of complexes can be understood on illustrating one-electron transition for assigning absorption bands and excited states (mononuclear complexes). The d-orbital splits due to mixing with σ−donor and π−donor & accepter orbitals of the ligand. So, the characteristic absorption bands correspond to the excitation between these split d−orbitals (with partially filled d−orbital). These d−d ligand field (LF) transition involve MOs, which are mainly metal in character and therefore, the resulting excited states are often called metal centered excited states (MC*). In complex having center of symmetry, LF bands are Laporte forbidden and have very low value of molar extraction coefficient. However, metal-to-ligand charge transfer (MLCT) and lignd-to-metal charge transfer (LMCT) bands process higher intensity due to change in the dipole moments between ground and excited states. The one-electron transition in octahedral mononuclear complexes is shown in Fig. 2.2.

Where, IL = Intraligand or ligand centered transition,

MLCT = Metal-to-ligand charge transfer,

LMCT = Lignd-to-metal charge transfer, and.

LF = Ligand filled transition.

The IL transitions are actually intraligand or ligand centric transition represented by $\pi_L \rightarrow \pi*_L$ excitation. So these one electron transitions provide a convenient framework to understand the nature of the excited states formed;

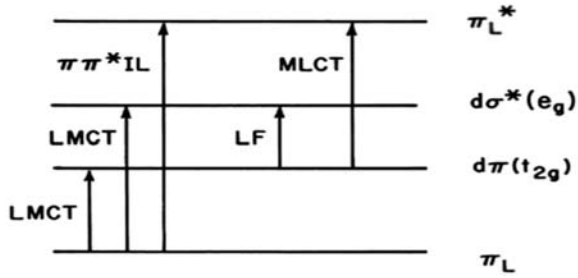

FIG. 2.2 One-electron transition in octahedral mononuclear complexes. *Adapted from Ford, P.C., 2016. From curiosity to applications. A personal perspective on inorganic photochemistry. Chem. Sci. 7 (5), 2964–2986. With permission.*

however, theoretical calculation has predicted more mixing of the excited state characters than what is depicted? In case of $[Ru(NH_3)_5(py\text{-}x)]^{2+}$, where (py-x is substituted pyridine), and other related complexes, such as $[Ru(NH_3)_5(pz)]^{2+}$ (where pz = pyrazine), the strong absorption band in visible region was attributed to MLCT transition, which is allowed singlet to singlet transition. But in UV region, the absorption band corresponding to a transition ($\pi_L \rightarrow \pi*_L$) is IL in nature. S_o, the question arises that at what point one would expect to obtain the LF absorption for these low spin d^6? The absorption spectrum of $[Ru(NH_3)_6]^{2+}$ can be taken as an empirical model, in which the spectrum does not include any π-unsaturated ligands. The electronic spectrum of this complex showed two absorption bands; one at 390 nm ($\varepsilon = 35\ M^{-1}cm^{-1}$) and other at 275 nm ($\varepsilon = 640\ M^{-1}cm^{-1}$) as predicted by group theory ($^1A_{1g} \rightarrow {}^1T_{1g}$) and ($^1A_{1g} \rightarrow {}^1T_{2g}$) respectively. Here, the higher intensity of the band at 275 nm is due to mixing of a charge transfer-to-solvent transition (CTTS). In $[Ru(NH_3)_5(py\text{-}x)]^{2+}$ ions, the analogous LF bands are expected at comparable energies for the $[Ru(NH_3)_5(py\text{-}x)]^{2+}$ ions, but they are enveloped by much strong MLCT bonds.

The photoreaction and their mechanism are also proposed on the basis of quantum yield (Φ), which indicates that the efficiency of the photochemical reaction may have higher values as almost equal to units or in many reactions, Φ is very small. The key points here is the denominator in the definition of Φ as:

$$\Phi = \frac{\text{Number of molecules taking part in the photochemical reaction}}{\text{Number of quanta of light absorved}} \tag{2.5}$$

As the photochemical reaction is possible only, when light is absorbed, the denominator in this expression of Φ is main factor for generating either high or low value of Φ. Kinetics of the photochemical reaction is an important aspect in the sense that delivering a drug at a proper targeted

biological organs, the overall rate of the photochemical reaction has the significant importance.

The rate of photochemical reaction is expressed as:

$$\text{Rate} = \Phi \times I_a, \tag{2.6}$$

where I_a is the intensity of the light absorbed (in unit of "Einstein" per unit time) and Φ is the quantum yield (1 E = 1 mol of photons). A solution containing only one photoreactant, which absorbs incident light, $I_a = I_0 (1-10^{-Abs})$ (where absorbance (A) = εCl), where ε is the molar extension coefficient (L mol^{-1} cm^{-1}), C is the concentration of the photoreactant and "l" is the pathlength of the cell (cm). In such processes, there will be no unimolecular rate constant. When photolysis of $[Ru(NH_3)_5(py)]^{2+}$ is continuously carried out at 405 mm under light irradiation at ambient temperature, the photosubstitution reaction takes place and the quantum yields for pyridine and ammonia substitutions (Φ_{py} and Φ_{NH3}) were found to be 0.045 and 0.063, respectively. This wavelength is close to λ_{max} of the spin−allowed MLCT band (407 mm) and therefore, it can be said that majority of the absorbed photons resulted into MLCT excitation.

The understanding of nature of excited state can give insight of the type of photochemical reaction. But sometimes, correct conclusion could not be drawn. The behavior expected for MLCT excitation was not found in the case of photosubstitution reaction having an oxidized metal center and reduced pyridine $[Ru^{III}(py)]^{2+}$, but it is known that Ru(III) complexes are not thermally very labile. In the opposite situation, the MC excited state, in which an electron is promoted from a non-bonding or even π−bonding MO to σ* relative to the metal−ligand bond will appear as the precursor for the ligand photosubstitution. If this is true, then the hexaammine complex $[Ru(NH_3)]^{2+}$ is relatively labile toward photodissociation of NH_3 ($\Phi_{NH3} = 0.27$ at $\lambda = 405$ mm). Such conclusions are drawn on the assumption that the mechanism for excited state ligand labilization is mainly dissociative in nature. It was confirmed that for $[Ru(NH_3)_5(py)]^{2+}$, the ^{3}MC excited state is almost dissociative in character.

This discussion leads to propose that the excitation state responsible for the photosubstitution reaction was the outcome of the fast internal conversion (IC)/Inter System Crossing (ISC) from MLCT states, which are populated by excitation to MC excited states (these states are not observed spectroscopically) (Fig. 2.3).

This observation that the photolabilization of aqueous solution of $[Ru(NH_3)_5(py)]^{2+}$ does not depend mainly on the wavelength of excitation indicates that the lowest energy excited state (LEES) are responsible for these photosubstitution reactions. In this framework, another conclusion can be drawn that the ligand substituents can be used to tune the excited state energies, where the ^{3}MLCT is the LEES. In that case, considerable decrease in the photolability will be observed.

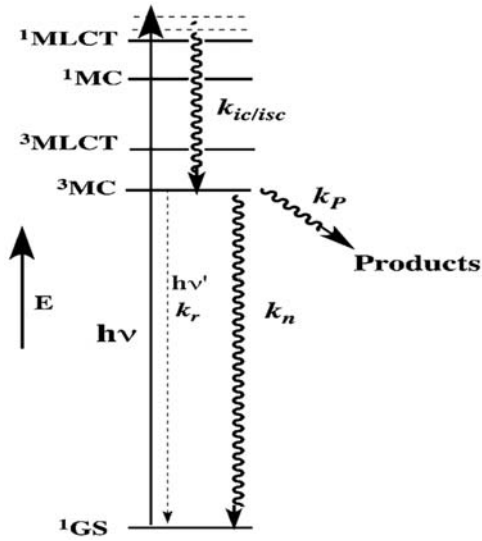

FIG. 2.3 Proposed ES diagram to explain photoaquation of aq. $Ru(NH_3)_5(py)^{2+}$ upon irradiation of MLCT bands. k_P is the rate constant for reactions to photoproducts. K_{ic}/i_{sc}, k_n and k_r are rate constants for internal conversion/intersystem crossing to a lowest energy metal centered excited state, nonradiative deactivation to the ground state ^{1}GS and radiative deactivation (emission), respectively. *Adapted from Ford, P.C., 2016. From curiosity to applications. A personal perspective on inorganic photochemistry. Chem. Sci. 7 (5), 2964–2986. With permission.*

Thus, the tuning of excited state can be shown by study of photoreaction of a series of $[Ru(NH_3)_5(py{-}X)]^{2+}$ complexes. It was observed that electron withdrawing substituents, which give red shift ($\lambda_{max} > 470$ nm), resulted into dramatically less photolability than those with substitution, which gives less value of λ_{max} (blue shift).

The tuning of MLCT/MC states by using various substituents is being used with many systems including those based on the Ru(II) polypyridyl complexes are of interest from solar energy conversion point of view. Similarly, Ir(III) phenylpyridyl complexes have been employed for orange light exciting diodes (OLED) application. The kinetics of excited state is much complex due to many states formation and deactivation processes involved. The kinetics becomes more complicated, when more than one excited state is involved for the chemical or photoluminescence property. The reaction kinetics envisaged form Jablonski diagram can guess that the excited state of lowest energy lies on the potential surface with very well defined minima. This is called bound excited state. There exists an energy boundary greater than k_BT (where k_B is the Boltzmann constant) for the bound excited state to decay along any pertinent reaction coordinate (Fig. 2.4).

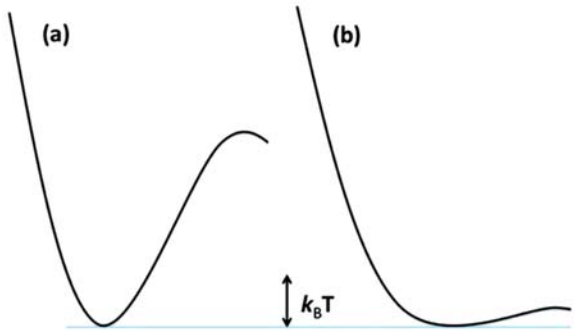

FIG. 2.4 Potential surfaces for (A) a bound excited state where the barrier is $>k_BT$ and (B) a dissociative ES where the barrier is $<k_BT$. Since k_BT is temperature dependent, if any barrier is present, an ES that is dissociative at a high T, may behave as a bound state at low T. *Adapted from Ford, P.C., 2016. From curiosity to applications. A personal perspective on inorganic photochemistry. Chem. Sci. 7 (5), 2964–2986. With permission.*

There are two possibilities:

- A bound exicted state having barrier greater than k_BT, and
- A dissociative exicted state having barrier less than k_BT.

Here, it is clear that k_BT is dependent on temperature, the excited state may exhibit a bound state at low temperature because at any barrier, the excited state at higher temperature will be dissociative in nature.

If the barrier is less than k_BT, the possibility of having a dissociative state is there. In this situation, they will have shorter lifetimes and their kinetics cannot be treated by classical kinetic methods.

The quantitative photochemical studies of ammine complex of Rh(III) revealed that the kinetics and mechanism of ligand photossubstitution reaction involves metal centered (MC*) excited states: These are d^6 complexes and metal system with this electron configuration (d^6) has found application in dye–sensitizerd solar cells (DSSCs) and organic light emitting diodes (OLEDs). Therefore, metal centered excited states are also important, even when the initial excitation is of MLCT nature. It can be seen that in Rh(III) ammine complexes, the absorption spectra is mainly due to the spin allowed LF bands ($^1A_1 \rightarrow {}^1T_2$, $^1A_1 \rightarrow {}^1T_1$ for the octahedral complex $[Rh(NH_3)_6]^{3+}$) whereas, the emission spectra exhibited the character of lowest energy triplet metal centered excited state (^{3}MC*) in aqueous solution.

Studies on the photosubstitution reactions and lumininiscent behavior of $[Rh(NH_3)_6]^{3+}$ revealed that these reactions and luminescence are independent of excitation wavelength, which indicated that initial LF excitation to ^{1}MC* states was followed by efficient IC/ISC to give lowest energy ^{3}MC* state

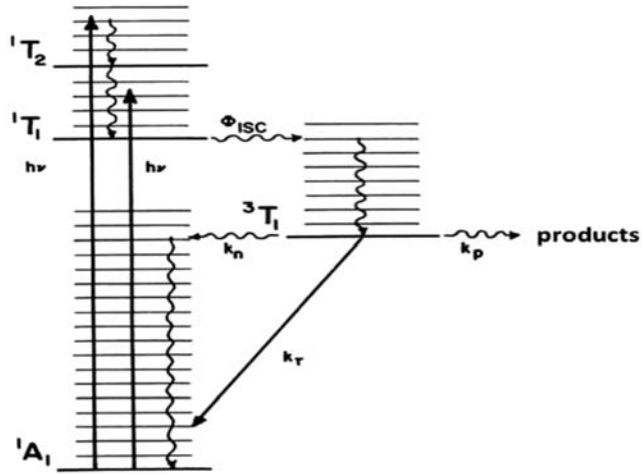

FIG. 2.5 Excited state diagram of MC states in $[Rh(NH_3)_6]^{3+}$. *Adapted from Ford, P.C., 2016. From curiosity to applications. A personal perspective on inorganic photochemistry. Chem. Sci. 7 (5), 2964–2986. With permission.*

($^3T_1$). This $^3T_1$ is mainly responsible for the photoreaction or emission (Fig. 2.5).

Therefore, the photochemical reaction and emission quantum yield can be treated in terms of rate constants of excited states.

2.3 Photoluminescence in coordination compounds

Rare earth ions like Eu^{3+}, Sm^{3+}, Gd^{3+}, Tb^{3+}, etc. form complexes with bidentate ligands, and there occurs emission due to transition within the metal energy levels, though they are Laporte forbidden. The energy levels become populated by intramolecular energy transfer in the complex, when ligand absorbs the radiation. The fluorescence and phosphorescence from ligand moiety can be observed, if the emission state of metal lies higher than the lowest triplet state of ligand moiety. The uranyl ion (UO_2^{2+}) is also highly luminescent.

The emission properties are observed in transition metal complexes with d^3 (Cr^{3+}, Co^{3+}) and d^6 (Ru^{2+}, Rh^{3+}, Os^{2+} and Ir^{3+}) configurations. In these cases, the nature of emissive transition is d-d transition and dominance of spin-forbidden phosphorescence in seen. The fluorescence efficiency is low due to spacing and coupling of lowest excited vibration levels with the ground state vibrational levels.

In these cases, fluorescence was found to show broad band (and large Stoke's shift) indicating the distortion in the geometry of excited states. Phosphorescence is identified with very small Stoke's shift and at low

temperature in glassy solution, the vibration structure is resolved. The phosphoroscence is due to the transition assigned as $^2E_g \rightarrow {}^4A_{2g}$, which coresponds to $T_1 \rightarrow S_0$ in Jablonski diagram. In these complex compounds, non-radiative internal conversion (IC) processes are relatively more prominent than the non-radiative ISC processes. Therefore, the spin-orbit coupling is not the sole deciding factor for the loss of luminescence. Therefore, if there are low-lying d-d states, then there will be absence of luminescence as in the complex having configuration d^1, d^7, d^8, d^9 and for most of the d^6 complexes.

If one focus on the emissive transitions in transition metal complexes, then these transition generally obey Kasha's rule and generated from the lowest excited state i.e., triplet (π, π^*) or triplet (d, π^*) state, and triplet (d-d) states. The emissive transition of the type of $^3(\pi, \pi^*)$ is observed in $[Rh(phen)_3](ClO_4)_3$. The ^{3}(d, π^*) transition was there is $[Ru(dpy)_3]Cl_2$ and ^{3}(d-d) transition in case of solid $[RhCl_2\ (phen)_2]Cl$. A weak fluorescence form Cr(III) complex was also observed occasionally. A very good luminescence was observed in $K_3[Co(CN)_6]$. It has also been proposed that in some cases, $^3(\pi, \pi^*)$ and ^{3}(d, π^*) states are formed from delocalized orbitals and ^{3}(d-d) state is formed from localized orbitals. It has been observed that the increase in the shift of the emission of chelate complexes in comparison to the free ligand is associated with the increase in the participation of d-orbitals in the emissive transition. A decrease in the lifetime of the chelate complex may also be attributed to the increase in d-character in molecular orbital. This gives a reasonable explanation for the behavior of metal complexes as quencher of excited state of π-electrons in organic compounds. In Rusy laser, the emissions from Cr^{3+} is the basis of functioning as laser.

Recent progress in exhibiting luminescence by metal complexes with photochromic units like azobenzene, spiropyrane and diarylethene, which undergo reversible photoisomerization between two isomers on irradiation with proper wavelength is very interesting. The emerging electronic and photonic devices have seen a progress due to investigations in the area of photoresponsive molecules and their light irradiation characters, which modulate certain physics and chemical properties. If the metal complex contains some photochromic units as ligands, then these ligands act as photoresponsive unit and such complexes are found suitable for advanced photonic applications such as photoswitching, photomemory, electronic conductors, electrochemical response, magnetic interaction, etc. These advanced properties are due to their high sustainability, resolution, contracts and quick response time in luminescence technology.

Luminescence−switching properties of metal complexes having photochromic units as ligand are due to characteristics electronic transitions, which are classified as:

- The $\pi-\pi^*$ transition of the ligand,
- MLCT and LMCT transitions in transition metal complexes, and
- f-f transition in lanthanide complexes

Therefore, the knowledge and understanding of their transitions will be useful in luminescence intensity modulation for applications in smart molecular switches. These advanced photonic applications will provide avenues for synthesizing such new different metal complexes, which will be also useful in devices with photonic memory and photosensing properties.

Traditionally, the inorganic photochemistry and photophysics was dominated by rare earth and costly metals, but now complexes of low cost and abundant metals have also shown their potential to photoemit or fluorescence. The first row transition metal complexes have also shown their unexpected reactivity and photoluminescence behavior due to increase in the understanding of the nature of excited states.

After the great progress in the conceptual understanding of excited states, a broad range of elements in various oxidation states show the photoluminescence behavior. The complexes of vanadium, chromium, manganese, iron, cobalt, nickel, copper, etc. now show luminescence properties, which were not known earlier in detail. In 3d-series metal, the ligand field is poor as compared to 4d- and 5d- complexes, due to poor spatial overlap of metal d-orbitals with ligand orbitals. Therefore, the complexes having partially filled 3d-orbitals produce very many metal centered excited states with very less spacing between them and also less space with ground state. This situation is somewhat precious, because it will allow a series (cascading) of non-radiative processes from MC state to the other and ultimately back to the ground state. However, in some cases, the situation of metal-ligand bond is much different (from ground state) in some MC state as in the case of promotion of d-electrons from non-bonding to antibonding orbitals. In such situations, the excited states are called distorted and this can be seen in the shift of the potential well along a certain nuclear coordinate (e.g., M−L bond distance). Therefore, the efficiency of the crossing barrier from one potential well into next lower is very less and this will cause rapid non−radiative processes to occur, whereas in 4d- and 5d-complexes, the spacing between MC states and also between MC and ground state is large, so the lowest MC state can be luminescent and photoactive because the efficiency of non−radiative processes is less, when the excitation energy is released through more number of vibrational levels.

High energy MC states open the door for formation of fundamentally different excited states at lower energies (keeping the spacing with ground state large enough). This is the case, when electron density shifts from metal to ligand or from ligand to metal. The most important state, which govern the photochemical and photophysical properties is the lowest excited state; that is MLCT or LMCT states. In these charge transfer states, redox properties are very much different from the ground state, making them to involve in photoredox chemistry with organics or to act like dyes in inorganic semiconductor

solar cells. Ligand-to-ligand charge transfer (LLCT), in which the electron density shifts from one ligand to another ligand, can also be useful to exhibit luminescent properties. This is totally different from what is called intraligand (IL) excitation, in which the electron density is redistributed within the π− conjugation framework of the ligand.

Contrary to the organics, the fast ISC processes in many metal complexes from excited singlet to lower lying triplet excited states are due to greater spin−orbit coupling. This phenomena has significance with regard to photoreactivity (which could not be observed from singlet state) and the triplet excited state being more stable (higher lifetime) produced an improved kinetic reactivity. Also, the photo-induced electron transfer from triplet states will result into primary photoproduct, which undergoes less charge recombination. This will increase the quantum yield of the photoredox reaction. Various applications highlight the important role played by metal complexes like luminophores in organic light emitting diodes (OLEDs), and light emitting electrochemical cells (LEECs), photocatalysis in synthetic photochemistry and artificial photosynthesis, harnessing the solar energy in dye−sensitized solar cell (DSSCs), etc. Therefore, search for newer photoactive complexes of low cost and abundantly available metals will bring many laurels to this field of photochemistry.

Emissions of Cu(I) and Cr(III) complexes in solution phase at room temperature have been known earlier. The progress in key concepts and lifetime of excited state has motivated the scientists to synthesize complexes with exceptional illumination properties. Complexes of cobalt and nickel have also attracted the attention of inorganic chemists for this purpose. The most abundant transition element iron has become a point of interest for chemists, while manganese and vanadium complexes have exhibited luminescence in solution at room temperature. This has revolutionized the present field. When a compound exhibited emissions in solution at room temperature, this indicates that the lifetime of excited state are sufficiently more from diffusion controlled biomolecular reactions and therefore, such compounds become suitable for photochemical applications, which are very advanced in nature as compared to simple lighting.

The important complexes in the term of photoactivity are there, in which the metal is directly involved in shaping the photochemical and photophysical properties. Complexes, in which IL excitation plays a prominent role, will have different mechanism for luminescence. Therefore, LLCT, MLCT, LMCT and MC excited states are more relevant for $3d^n$ configuration ($n = 2-10$). Examples of base metal complexes showing luminescence are as follows: $3\ d^{10}$ (Cu(I) complexes as LLCT emission), $3\ d^6$ (Mn(I) and Cr(0) complexes) and $3\ d^8$ (Ni(II) complexes, as MLCT emission), $3\ d^0$ (Sc(III)), $3\ d^3$ (Mn(IV)), $3\ d^5$ (Fe(III)) and $3\ d^6$ (Co(III)) complexes as LMCT emission, $3\ d^2$ (V(III)), $3\ d^3$ (Cr(III), Mn(IV)) and $3\ d^6$ (Co(III)) complexes as MC emission have been reported.

A drastic change was observed, when two-coordinated Cu(I) complexes, (which are LLCT luminophores as well as LMCT emitters), got change in the direction of charge transfer (Wegeberg and Wenger, 2021). Change in the direction of charge transfer (i.e., from MLCT to LMCT) has resulted into the use of these complexes in dye-sensitized solar cells; however, for luminescence properties of LMCT or LLCT emitters are very competitive with MLCT luminphores. This is especially true for lower Cu(I) LLCT emitters. This shows a paradigm shift in the conceptual framework of metal complexes.

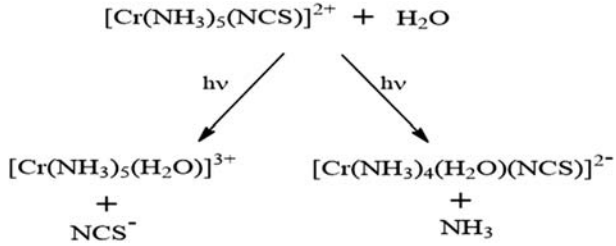
Therefore, traditionally the photoemissions was due to MLCT and MC transitions, but in addition in this, LMCT and LLCT transition also resulted into the emission for complexes of 3d- and other elements. Also, molecular complexes of abundant main group elements have attracted chemists to act as luminophores and give an insight to control the non-radiative pathways.

2.4 Photochemical processes

As it is known that in metal complexes, non-radiative activation of low lying energy states is fast and therefore, the photochemical reactions from these states must possess zero activation energy. In case of transition metal complexes; both $^4T_{2g}$ and ^2E_g are photoactive states but these may take different pathways. There are three fundamental photochemical reactions for coordination compounds. These are:

(i) Photosubstitution,
(ii) Photorearrangement, and
(iii) Photoredox reactions.

2.4.1 Photosubstitution reactions



This is further divided into three categories i.e., aquation, anation or ligand exchange reactions.

- **Photoaquation reactions**: The general equation for photoaquation reaction can be represented as:

$$[Cr(III)L_6] + H_2O \xrightarrow{hv} [Cr(III)L_5(H_2O)] + L$$

In this reaction, M−L bond is heterolytically cleaved. In some specific Cr(III) complexes of O_h symmetry, such aquation reactions are efficiently observed, when $^4T_{2g}$ states lies sufficiently above the ^2E_g state. If the energy difference between these two states decreases, the efficiency of the aquation reaction also decreases. This is observed for $[Cr(NH_3)_6]^{3+}$ on successive aquation. The labileness of ligand NH_3 and H_2O become reversed in the

thermal and photochemical reactions. The two aquation modes for $[Cr(NH_3)_6(NCS)]^{3+}$ in 0.1 H_2SO_4 are

Here, both $^4T_{2g}$ and ^2Eg states are photochemically active and the ratio of $\Phi_{NH3}/\Phi_{\overline{NCS}}$ depends upon the wavelength.

This photoaquation reaction can also be obtained through photosensitization by a mechanism known as energy transfer from biacetyl and acridinium ion in the same solvent. When biacetyl is used as a sensitizer, phosphoresence was quenched, but fluorescence remained unaffected. No degradation of biacetyl and release of NH_3 was observed. The ratio $\Phi_{NH3}/\Phi_{\overline{NCS}}$ was found to be greater than 100. When acridinium ion was used a sensitizer, fluorescence was quenched, NH_3 and NCS both were released (though NH_3 was predominant). The release of NCS^- was less in presence of O_2 and hence, the triplet state of the sensitizer was involved. The Φ_{NH3}/Φ_{NCS} was found to be 33 for $^4T_{2g}$ states and eight for ^2E_g state. These observations clearly indicated the release of NH_3 from $^4T_{2g}$ and NCS from ^2E_g states.

These reactions were found useful in the synthesis of coordination compounds. The photoaquation of $K[Cr(NH_3)_2(SCN)_4]$ and $[Cr(Urea)_6]Cl_3$ can be employed as efficient actinometers in the range of 316−750 nm. The photochemical reaction for $[Co(CN)_6]^{3-}$ is

$$[Co(CN)_6]^{3-} + H_2O \xrightarrow{h\nu} [Co(CN)_5(H_2O)]^{2-} + CN^-$$

This reaction takes place without any complication and its quantum yield is also higher ($\Phi = 0.31$).

- hν **Photoanation reaction**: Such reactions are common in Cr(III) complexes, and these can be represented as-

$$[Cr(H_2O)_6]^{3+} + NCS^- \xrightarrow{h\nu} [Cr(H_2O)_5(CNS)]^{2+} + H_2O$$

$$[Cr(H_2O)_6]^{3+} + Cl^- \xrightarrow{h\nu} [Cr(H_2O)_5(C1)]^{2+} + H_2O$$

Such reactions play a vital role in the synthesis of new coordination compounds using solution phase reactions.

- hv **Ligand exchange reactions**: When carbonyl metal complexes $[M(CO)_6L]$ was irradiated with light in presence of excess L, the substituted complex is produced.

$$[M_0(CO)_6] + L \xrightarrow{hv} [M_0(CO)_5L] + CO$$

Where L may be NH_3, $(C_2H_5)NH_2$, $(CH_3)_2NH$, $(CH_3)_3N$, $(C_2H_5)_3N$ or other amines. The pentacarbonyl complex formed here may undergo further substitution reaction. In case of $[Fe(CN)_6]^{4-}$, the photosubstitution of dipyridyl ligand takes place as:

$$[Fe(CN)_6]^{4-} + dpy \xrightarrow{hv} [Fe(CN)_4(dpy)]^{2-} + 2\ CN^-$$

When mix ligands are involved, the photoreactivity can be predicted by considering the strength of ligand fields. In case of a complex of O_h symmetry, the axis which possess weakest average field (estimated from the position of its respective ligands in the spectrochemical series) will be labilized. If the labilized axis has two different ligands, then the ligand having greater field strength will be replaced first as in the case of $[Cr(NH_3)_5Cl]^{2+}$.

The $NH_3-Cr-Cl$ is a labilized axis and not the $NH_3-Cr-NH_3$. So, the strong ligand NH_3 will be replaced preferentially along $NH_3-Cr-Cl$ axis; however, prediction may deviate, when steric and solvation effects are present. If the symmetry of the complex is lowered, then the position of states also changed and due to this, the nature of reaction also changes.

Photosubstitution reaction of Ru(II) imine complexes are good examples of use of these complexes in the field of photobiology and photodynamic therapy. The mechanism of the photosubstitution reaction of these Ru(II) complexes can be understood using the simple Jablonski diagram.

The photoreactivity of Ru(II) complexes is affected with MLCT transition in visible region due to absorption. These complexes contain one or more diimine ligands (bpy = 2,2′- bipyridine, phen = 1,10-phenenanthrine, etc). and one or more ligands, which can be easily labilized in the excited state. Here, three states of ^{3}MLCT are split. The largest wavelength absorption in the visible region corresponds to MLCT transition. After excitation by ISC, triplet ^{3}MLCT state is formed (very fast of the order of femto seconds i.e., 10^{-15} s) with almost unit efficiency. Relaxation of the triplet state to the ground state is in the range of nanoseconds and includes internal conversion, resulting into triplet ligand field state (^{3}LF). Recent advances in this field have provided more insight into the energetics of MLCT and LF states, because these two important states are involved in the photosubstitution reactions. So, more understanding about the nature of these states will further the research in the

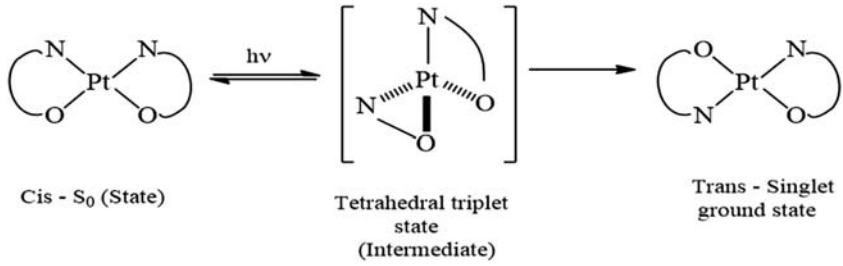
development of newer complexes acting as therapeutic agents. In case of bidentate ligand, Ru(II) complex also involves new ^{3}MC states (which are involved in the formation of trans−photoproduct).

2.4.2 Photorearrangement reactions

These are classified into four categories:

(i) Geometrical isomerization,
(ii) Photoracemization,
(iii) Linkage isomerization, and
(iv) Ligand rearrangement (or Ligand exchange reaction).

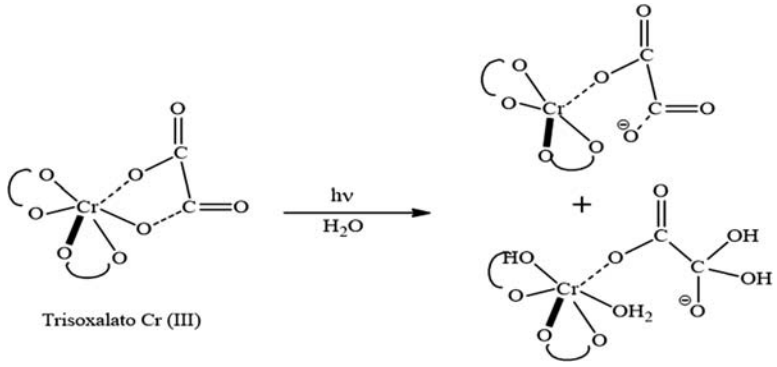
- **Geometrical isomerization**



hv The cis−trans isomerization occurs through the ligand field transition (Scandola et al., 1967)

$$\text{Cis} - \text{bis(glycinato)} \quad \text{Pt(II)} \xrightarrow{hv} \text{trans} - \text{isomer}$$

But,



$$\text{trans} \longrightarrow\!\!\!\!\!\!\times \text{cis}$$

This kind of photochemical process involved intramolecular twist mode without bond cleavage. The triplet state formed with pseudo−tetrahedral geometry is the intermediate in this reaction. This process is photochemically allowed but thermally forbidden on the basis of symmetry rules (Richardson et al., 1971).

- **Photoracemization**

Ligand field transition may also result into the racemization in case of trisoxalatochromium (III) (Richardson et al., 1971).

The racemic mixture can be separated and this photoreactivity has scope in synthesizing those stereoselective and enantioselective (chiral) coordination compounds, which could not be synthesized by other thermal reactions. This reaction also exhibit deuterium isotope effect.

- **Linkage photoisomerization**

Linkage isomerism in coordination compounds is very fascinating aspect of synthetic coordination chemistry. In this isomerism, only the mode of the attachment of an ambidentate ligand to the metal ion is changed. Various ambidenttate ligands like NO_2^-, SCN^-, $S_2O_{3^{2-}}$, CN^-, $SeCN^-$, SO_3^{2-}, etc. have shown this type of isomerism.

$$[Co(NH_3)_5(NO_2)]^{2+} \xrightarrow{hv(solid)} [(NH_3)_5 - Co(ONO)]^{2+}$$

The nitro−nitrito photoisomerization takes place in solution using an intra molecular mode, which involves the homolytic cleavage of $Co-NO_2$ bond and then two fragments are joined back with altered attachment (as Co−ONO). This complex shows CT and LMCT characters at 239 and 325 nm and a ligand field transition at 458 nm.

$$[Co(NH_3)_5.(NO_2)]^{2+} \xrightarrow[\text{in 0.1 N } HCLO_4]{\text{CT and LF}} [Co(NH_3)_5.NO_2]^{2+}$$

Isomerisation Reaction → $[Co(NH_3)_5(ONO)]^{2+}$

Redox Reaction → $Co^{2+} + 5\,NH_3 + NO_2$

The nitrosyl linkage isomers (metatable states) in solid state are useful for optical data storage. This kind of isomerism finds application in

photoswitching. Photoisomerization of ruthenium bis sulfoxide molecular photoswitch $[Ru(bpy)_2(bpSO)]^{2+}$ takes place in gas phase. When irradiated in gaseous phase, there is direct switching of the S,S−isomer to O,O−isomer by absorption of single photon, but in solution phase, stepwise isomerization occurs with each sulfoxide ligand switching turn by turn. This change in the dynamics of isomerization may be due to fast vibrational quenching, which suppresses isomerization in solution. The spectra of this photoisomerization reveals two bands: One corresponding to ligand centered (S,O−isomer) (π, π^*) transition and other is MLCT band (S,S−isomer).

- **Ligand rearrangements**

The photochemical exchange of ligand is also a very attractive synthetic methodology for preparing new coordination compounds. In case of cobalt complexes, this is represented as

$$[Co(CN)_5(NO)]^3 + {}^*CN^- \xrightarrow{hv} [Co(CN^*)_5(NO)]^{3-} + CN^-$$

These reactions are very significant in biologically processes, where the release of biological active species is concerned. The process of chemotherapy using photoactivation involves the light−induced cleavage of chemical bond that releases biological active fragment. Therefore, complexes having such tendency are called photoactivated chemotherapeutic complexes. Ru(II) complexes have been investigated in much detail and still lie at the forefront of researches in photochemistry. The excited states, which involve various types of reactions exhibited by Ru(II) complex, are MLCT and MC types. These are main responsible excited states for their photophysical and photochemical properties. The photorelease of monodentate and bidentate ligands in these complexes give new hypothesis for mechanism of the ligand exchange reactions. The release of bidentate ligand involves new ^{3}MC states of flattened geometry. Therefore, the interaction of MLCT and MC excited states play a key role for both; the photophysics (i.e., photoluminescence, electron or energy transfer) and photochemical (photoisomerization, photorelease, etc) properties. Here, in case of Ru(II) complex, the release of monodentate ligand takes place through the excited triplet state (^{3}MLCT) and the release of bidentate ligand takes place by involvement of the triplet excited state called ^{3}MC state (having flattened geometry). The ^{3}MC states are mainly involved in the formation of trans−product. Such distorted ^{3}MC state formation is a common feature for Ru(II) complex such as $[Ru(bpy)_3]^{2+}$ and also for other complexes, where such ^{3}MC flattened states were identified. One important aspect of these ^{3}MC state is their accessibility form ^{3}MLCT state along with the minimum energy paths, which connect these two (^{3}MC and ^{3}MLCT) and relative reach toward minimum energy crossing points to singlet ground state surface of both; the reactant and photoproduct. The population of intermediate

states along the photoinduced release of bidentate ligand to give final photoproduct.

In further steps, there will be preferential relaxation modes by excited states as not all, but certain specific ^{3}MC state resulted into release of ligand. The knowledge and understanding of the interplay between ^{3}MLCT and ^{3}MC state will provide a predictive tool for synthetic coordination chemists to control and fine tune the photochemical behavior with the purpose to influence selective ^{3}MC population to obtain efficient photo-release of ligand.

2.4.3 Photoredox reactions

Photoredox reactions take place via two modes and these are intermolecular and intramolecular reactions. In solution, the photoredox process may be intermolecular, when the complex reacts with another species present in the solution but when the reaction takes place between the central atom and one of its ligand, then it is called intramolecular redox reaction.

When a complex is irradiated, the central metal ion become strongly oxidizing in nature due to ligand field transition (d−d transition). It will result in intramolecular reduction of the central metal ion.

$$2[\mathrm{Fe(III)(C_2O_4)_3}]^{3-} \xrightarrow{\mathrm{hv}} 2[\mathrm{Fe(C_2O_4)_2}]^{2-} + 2\ \mathrm{CO_2}$$
$$[\mathrm{Co(III)(NH_3)_5I}]^{2+} \xrightarrow{\mathrm{hv}} \mathrm{Co(II)} + 5\ \mathrm{NH_3} + \mathrm{I}$$

The ferrioxalate is a good actinometer, which works in the UV and visible region up to 400 nm. The actinometer functions through redox photoreaction. In some low-valence hydrated cations such transition may result into photooxidation

$$\mathrm{Fe(II).H_2O} \xrightarrow{\mathrm{hv}} \mathrm{Fe(III)} + {}^{-}\mathrm{OH} + \mathrm{H}$$

Also, the

$$[\mathrm{Fe(thionine)}]^{2+} \underset{\text{dark}}{\xrightarrow{\mathrm{hv}}} \mathrm{Fe}^{3+} + \mathrm{Semithionine}$$

This reaction reverts back in dark. These reversible photoredox reactions are useful in the conversion of light energy into the electricity (solar cells). The irradiation of the complexes at LMCT band will be conducive for photoreduction

$$[\mathrm{ML_n}]^{Z+} \xrightarrow{\mathrm{hv}} \mathrm{M}^{(Z-1)} + (\mathrm{n}-1)\mathrm{L} + \mathrm{Oxidation\ \ product\ \ of\ \ L}$$

Here, the M−L bond will be homolytically cleaved due to excitation. Such photoreactivity is not found in the ligand field bands (d-d transition) and if redox reaction takes place under such excitation, it is likely to hide a low lying reactive CT band under its envelope. It is not essential in such reactions that ligand should decompose, but if the central metal ion forms a stable complex

with one lower (or higher) oxidation state, then the stable product (complex) formation is due to intramolecular redox reaction.

$$[IrCl_6]^{2-} \xrightarrow[H_2O]{h\nu} [IrCl_5(H_2O)]^{2-} + Cl^-$$

In case of intermolecular photoredox reaction, the light induced electron transfer takes place between a complex and any other species available in the solution. In this case, an oxidized or reduced form of the complex is produced.

$$[ML_n]^{z+} + X \xrightarrow{h\nu} ML_n{}^{(z+1)} + X^-$$
$$[ML_n]^{z+} + Y \xrightarrow{h\nu} ML_n{}^{(z-1)} + Y^+$$

If the new complex formed is unstable, then decomposition reaction was observed

$$[Co(NH_3)_6]^{3+} + I^- \xrightarrow{h\nu} [Co(NH_3)_6]^{2+} + I$$
$$[Mo(CN)_8]^{3-} + H_2O \xrightarrow{h\nu} [Mo(CN)_8]^{4+} + H^+ + OH$$

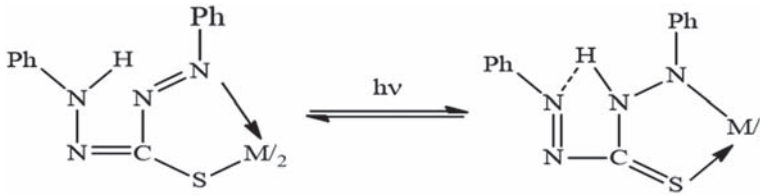
Here, no decomposition takes place in the reaction of molybdenum complex. The excitation is there in ligand field band region. When the newly formed complex is stable, an electron may be ejected and hydrated electron is obtained (e^-_{aq}) as

$$[Fe(CN)_6]^4 + H_2O \xrightarrow{h\nu} [Fe(CN)_6]^{3.} + e^- aq$$

This corresponds to the type charge transfer—to—solvent (CTTS) transition. Photoejection of electron can also take place, if LMCT band increase the charge density toward the periphery of the complex.

2.5 Applications

2.5.1 Photochromism



The phenomenon of photochromism is shown by systems, in which photochemical reaction is complemented by a reverse thermal reaction and as a result, the change in color was observed, and this color appeared again in dark. The reaction of a photochromism can be represented as:

$$A \overset{h\upsilon_1 k_1}{\rightleftarrows} B$$

A photostationary state may exists here, where the photochemical (and thermal) reaction is balanced by reverse thermal reaction.

Various coordination systems were found to show photochromism. When 0.01 M $[Cr(CN)_6]^{3-}$ with 0.1 M cyanide ion was irradiated, a photostationery state involving mainly $[Cr(OH)_3(H_2O)_3]$ was formed and in the reverse reaction, mainly $[Cr(CN)_4(H_2O)_2]^-$ is formed in dark.

Similarly, $[Co(CN)_5I]^{3-}$ in concentrated iodide solution will show photochromism and gives $[Co(CN)_5(H_2O)]^{2-}$,which reverts back in dark. Such sequence also occurs in $[Cr(H_2O)_5(NCS)]^{2+}$. There may be cases, when k_{-1} (backward reaction rate constant) is very large than k_1 (forward reaction rate constant), then photostationary state will lie at far left of the equilibrium and therefore, photolysis will not be there. Such labile complexes may also be said as non-photosensitive material (of course incorrectly). The chelate formed by the ligand dithiazine, HD_z^-, is likely to exhibit photochromism. This was found true in the complexes, $Hg(HDz)_2$ and $Pd(HDz)_2$. The mercury complex is square planar and its structure is (Adamson, 1969).

Yellow orange in colour Blue in colour

(Where, $M = Hg^{2+}$, Pd^{2+}, etc.)

The photosensitivity of the system involves the absorption band due to absorption center in chelate ring. These chelate complexes are generally very much colored but do not seem to be photosensitive (as in the case of β-diketonate complexes). There are examples of complexes showing photochromism for which ΔG were determined from the entropy terms. The search is still on for systems having higher ΔH, as in the case of redox cycles of the type, such as

$$A \xrightarrow{h\nu} A^+ + e^-$$

Oxidized from $\xrightarrow{h\nu}$ Reduced form

This type of photochemical cell can form, if reaction of A^+ with reductant is slow. Such systems are normally not found, but system in which A is $[Fe(CN)_6]^{4-}$ and oxidized form is a redox dye (methylene blue) have shown such type of a photoredox cycling.

2.5.2 Chemical actinometers

A chemical actinometer or dosimeter is a chemical system (fluid, gas, solid or in microheterogeneous environment) that undergoes a light-induced reaction (at a certain wavelength, λ) for which the quantum yield (Φ) is accurately known. An actinometer is a chemical system (substance) or physical device

(thermistors, thermopiles, bolometer and photovoltaic cell) by which one can measure the intensity of light (UV and visible range). In photochemistry, the quantum yield (Φ) of the photochemical reaction is determined using the value of light intensity absorbed by the photoactive substance in the reaction. The Φ in expressed as

$$\Phi = \frac{\text{Number of molecules decomposed or formed per second per unit volume}}{\text{Number of quanta absorbed per second per unit volume}} \tag{2.7}$$

$$\Phi = \frac{\text{Rate of reaction}}{\text{Intensity of light absorbed}} \tag{2.8}$$

$$\Phi = \frac{-\frac{dc}{dt} \text{ or } +\frac{dx}{dt}}{I_0 \times \text{Fraction of light absorbed}} \tag{2.9}$$

Therefore, a simple method for standardization of a light source can be selection of a suitable photochemical reaction, where quantum yield is already known. In this method, the light absorption must remain constant during exposure. In the above expression, I_0 is the intensity of induced light and the fraction of light absorbed can be determined in a separate experiment. When quantum yield, Φ is known and extent of decomposition is also known, the intensity of incident radiation can be calculated in the unit of Einstein per unit volume per unit second. There are various photochemical reactions, which are being used as chemical actinometoes. They are only useful in a particular range of wavelengths. The following chemical actinometers for different ranges are suitable:

- **Ferrioxalate actinometer**

A solution of a potassium ferrioxalate $K_3[Fe(C_2O_4)_3]$ in 0.1 M H_2SO_4 is irradiated with oxygen free solution in 250−500 nm range of wavelength, which resulted into the formation of free Fe^{2+} ions. There ferrous ions can be analyzed spectroscopically by adding 1,10−phenanthroline to the final solution. The oxalate complex of the reduced Fe^{2+} ions does not absorb the incident radiation, but the precursor oxalate complex of Fe (III) ions has good absorption in this range. Such actinometer has an added advantage that quantum yield is almost independent of the environment effects, such as concentration of reactant and product, intensity of the incident light, and temperature of the solution.

- **Uranyl oxalate actinometer**

This actinometer is useful in the range 208−435 nm with average quantum yield of 0.5. Here, uranyl ion (UO_2^{2+}) acts as a photosensitizer for the decomposition of oxalate and therefore, the light absorption remained

constant. A prolonged exposure is needed for final oxalate titration with permanganate. This actinometer is relatively less reactive in comparison to ferrioxalate actinometer. It is also insensitive to incident light and temperature, but the photochemical reaction does not have a simple stoichiometry. The products formed are the U^{4+} ion, CO and CO_2. Now, it is not commonly in use practically.

$$H_2C_2O_4 \xrightarrow{h\nu} H_2O + CO_2 + CO$$

- **Malachite green leucocyanide (MGL) actinometer**

This is a useful actinometer in the range 220−300 nm, where it absorbs strongly. When malachite green was irradiated in slightly acidified ethanol, it is converted to ionized form (MG^+), which absorbs strongly at 662 nm. The quantum yield for its production is 0.91 for the given range.

- **Reinecke's salt actinometer**

This is a good chemical actinometer, which worked well in the range 316−735 nm, and therefore, it is useful in visible range. Reinecke's salt is ammonium salt $(NH_4)_3[Cr(NH_3)_2(NCS)]$. First, it is converted to its potassium salt and then it is used. Its ligand field band extend from 400 to 735 nm. When its aqueous solution is irradiated, the aquation of the complex takes place and thiocyanate ions are released. Quantum yield can be determined in terms of moles of a thiocyanate ion released per Einstein of light absorbed. The concentration of the actinometer should be kept such that 99% of incident light is absorbed. The pH is adjusted between 5.3 and 5.5. The quantum yield for this reaction is 0.27−0.34 for visible region.

Other complexes like hexakis(urea) chromium(III) chloride $[Cr(urea)_6]Cl_3$ and Co(III) of ammine complexes are also in use for actinometry experiments.

2.5.3 Release of CO/NO

One interesting use of photochemistry of complex can be observed in the Cr(III) complex of nitric oxide (NO). Nitric oxide plays very significant role in cardiovascular regulatory processes. The researchers are interested to develop method for controlled release of these molecules (small molecular bio-regulators like NO and CO) at targeted sites. Therefore, successful photo-uncaging and the mechanism of transport of these molecules to the targeted site requires the knowledge of fundamental photochemistry and photophysics of such molecules (NO, CO, etc). This aspect is illustrated by synthesizing metal complexes, which act as photoactivated CO or NO releasing moieties. Such complexes have a proper stability, non−toxic precursor, ability to activate NO or CO release using longer wavelengths excitation (particularly near

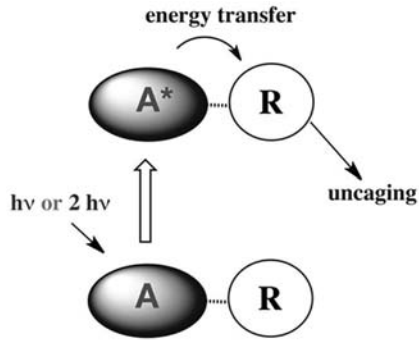


FIG. 2.6 Release of NO/CO. *Adapted from Ford, P.C., 2016. From curiosity to applications. A personal perspective on inorganic photochemistry. Chem. Sci. 7 (5), 2964–2986. With permission.*

infrared) and the tracking mechanism to locate these species in organisms. Photoluminescence (PL) is good imaging tool for tracking NO or CO (Fig. 2.6).

Here, A is the antenna molecule and R is the precursor of small molecule bioregulators (CO/NO) that is uncaged, if R is photosensitized. All the desired qualities were found in Cr(III)–O–nitro complex i.e., trans–[Cr(cydam)NO_2]$^+$ (this complex is abbreviated as CrONO and cylam is 1,4,8,11–tetraazacyclotetradecane). This is stable and non-toxic in nature also. The photoproduct in this case is NO. In the photochemistry of CrONO, the complex undergoes photodissociation of CrO–NO to give NO and Cr(IV)(O) species. This occurs from the lowest energy ^{2}MC state of the Cr(III) center. The main problem associated with CrONO to be used as photoreleaser of NO is that its longer wavelength absorption are LF bands with very low absorptivity (ε) and this complex contains center of symmetry. Therefore, the transition for the LF absorption is Laporte–forbidden. So, the rate of NO generation will be relatively slow, if the concentration of CrONO and light intensity are not high. This point was handled by attaching many organic chromophores to the CrONO type platform to serve as antenna to increase the absorption of light, and accordingly, the production of NO. Here, the anthracene molecule acts as (pentdant) antenna, which collects light and transfer the energy to CrONO and photosensitize the process of NO release from it.

Such new constructions exhibited antenna effect, but the absorption is not extended to visible light required for biological systems. Therefore, quantum dots (QDs) were used as photosensitizers as the absorption and emission of quantum dots can be tuned by varying the size of the nanoparticles (diameter). This idea worked well and using water soluble CdSe/ZnS core shell QDs and adding CrONO salts to such nanoparticles (3–8 mm core diameter) resulted into quenching of the quantum dot photoluminescence (QDPL) centered at 370 nm with increasing CrONO concentration.

In such situation, more NO were photogenerated than from solution containing only CrONO. Therefore, PL quenching and photosensitized product of NO are due to transfer of energy from the excited QDs to CrONO. But, the structure CrONO/QDs assemblies are not likely to be stable in physiological fluid, so there is a need of another protocol to be established, where CrONO and other such biomaterials are to be attached to the surface of QDs through a covalent bond. Therefore, more investigations in this area will be able to identify the excited state mainly responsible for particular photochemical reaction. The quantum yield, chemically and spectroscopic properties of product will help in identifying the excited state involved and these information are used to tune the excited state to direct the resulting photoreaction in a desired direction.

2.5.4 Photoredox catalysis

At this juncture, it is to be highlighted that greener organic synthetic routes have been established using a new concept known as "photoredox catalysis", which found a wide range of applications in the field of carbon dioxide reduction, splitting of water, design of new materials for solar cells and organic synthesis. This platform of photoredox catalysis uses mainly metal polypyridyl complexes and organic dyes to facilitate the conversion of light energy into chemical energy under very mild conditions. When light is allowed to fall on these molecules, excited molecules will be involved in single electron transfer (SET) with organic (and organometallic) substrates giving free access to open-shell reactive species. When visible light is used, where general organics don't absorb, the selective excitation of the photoredox catalyst will take place. The excited species can act as both; a strong oxidant and a strong reductant, simultaneously, which provides a unique environment for organic synthesis. This new type of photoredox catalysis provided avenues for the development of various novel synthetic methodology. At present, the field of photoredox catalysis has attracted large number of synthetic chemists as a strong strategy for activation of molecules.

This approach is based on the ability of the complexes and dye molecules to convert light energy into chemical energy by engaging SET with organic reactant, by which reactive intermediates are produced. This kind of approach gives a new type of reaction mechanism, where importance is given to multicatalytic strategies making it possible to obtain the formation of C−C, C−N, or C−S bonds. The important strategies to obtain the desired product stems form the ability of the photoredox catalyst to effectively convert light into chemical energy. Also, if ligand backbone on metal polypyridyl photoredox catalyst can be modified, then the redox properties of the complex can be fine tuned to access any desired product.

The mechanism of such photoredox catalysis can be understood by the formation of triplet excited state of the complex by energy transfer. Inspite of

rapid progress in this field, it is still in its infancy. The recent developments of dual photoredox catalytic platforms have produced novel activation mode, which direct the synthetic routes toward very highly regio- and enantio−selective products. These catalytic platforms are very useful in pharmaceutical industries in combination with flow technology to scale up the synthesis. In case of Pschorr reaction, it was found that the reaction could be catalyzed by $[Ru(bpy)_3]Cl_2$ producing phenanthrene in quantitative yields. This reaction was found to give higher quantum efficiency, when the photoredox catalyst was used as compared to direct photolysis of reacting mixture. The mechanism of photoredox catalysis can be represented as Fig. 2.7.

The catalyst used in these photoredox catalysis functions like a photoredox sensitizer or photoelectron transfer catalyst. Ruthenium complex acts like this. An electron in one of the photocatalyst metal centered t_{2g} orbitals is excited to a ligand centered π^* orbital in photoredox catalyst $[Ru(bpy)_3]^{2+}$ upon irradiation with light. This is the MLCT type transition and it will produce a species, where metal is effectively oxidized to Ru(III) and a single electron reduction takes place for ligand moiety. The initially occupied singlet MLCT state adopts rapid ISC to give lowest energy triplet MLCT state. This long lived triplet state is responsible for single electron transfer. The longer lifetime is due to spin−forbidden transition to singlet ground state. These are represented in Fig. 2.8.

2.5.5 Photochemiluminescence in ruthenium complexes

In some complexes of ruthenium (III), [Ru(III)−2,2′−bipyridyl−5−methyl−1,10−phenetherene] and in some other complexes also, the

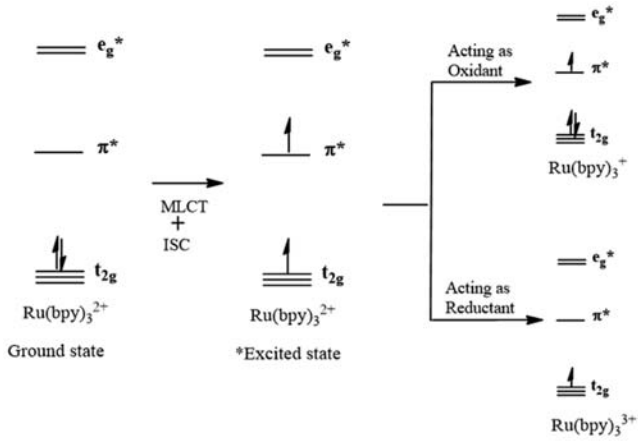

FIG. 2.8 $[Ru(bpy)_3]^{2+}$ as an oxidant and a reductant. *Adapted from Prier, C.K., Rankic, D.A., MacMillan, D. W., 2013. Visible light photoredox catalysis with transition metal complexes: applications in organic synthesis. Chem. Rev. 113 (7), 5322−5363. With permission.*

electrically excited states are obtained, when these complexes are allowed to reach with OH ions. Due to exothermic nature of this reaction, sufficient thermal energy is released, which excites the Ru(III) complex. When the excited state releaxes through radiative emission of the electronic energy, the phenomena of chemiluminescence is obtained. The general reaction for this chemiluminescence can be represented as

$$[ML_x]^{(n+1)+} + e^- (\text{from reductant}) \xrightarrow{h\nu} [ML_x]^{n+} + h\upsilon$$

Photochemiluminescence method is useful in the determination of antioxidant activities of carotenoids and antioxidant capacities of various fruit products, nutraceuticals and other dieting supplements.

A photosensitizer (S) on excitation by light gives two types of radicals: One is a photosensitizer cation (S^{*+}) and second is the superoxide anion radical ($O_2^{\bullet -}$). The free radicals are identified using chemiluminescence reagent (which functions as photosensitizer) and using oxygen radical detector. As the concentration of antioxidant increases, the intensity of chemiluminescence decreases.

2.5.6 Coordination compounds as triplet quenchers

Metallocenes function as very good quenchers of triplet excited state having energies between 177 and 280 kJ mol^{-1}. The rates of quenching process is nearly equal to the rate of diffusion controlled process. Metallocenes are also good sensitizers for cis−trans isomerization. Good examples of triplet state quenchers are ferrocene, $Fe^{III}(acac)_3$ and tris(dipivaloylnethanate) iron(III),

$Fe^{III}(dpm)_3$,etc. These coordination compounds quench the triplet states through the mechanism of electronic energy transfer. There exists high degree of correlation between the energy levels of these quenchers and plots of energy of triplet state v/s quenching rate constant. In all these complexes, ligand field excitation states are involved in quenching of triplet state and not the MLCT, LMCT or IL states. Therefore, understanding of triplet energy transfer to produce ligand field excitation in coordination compounds and the nature of triplet energy state of organic compounds will give an insight to these quenching mechanisms.

2.5.7 Coordination compounds as sensors

It has been reported that coordination compounds can be used as sensors for detection of highly toxic ion, CN^-, which is very necessary to maintain a greener environment and protect human health. The CN^- ion acts as ligand in coordination chemistry and its extreme toxicity causes concern also. So the facile and sensitive detection of such hazardous material CN^- ion is necessary. It can coordinate with some proper metals and form complexes and this coordination property of CN^- is harnessed in its detection. It also attacks the central metal ion and fluorescence may be produced. Therefore, coordination compounds can function as sensor for the detection of CN^- ions. It has attracted the attention due to the facile synthesis, clear & multianalyte detection and low detection limit.

The CN^- ions are detected by Cu(II) complexes; however, other metal complexes can also function as sensors. So, design and synthesis of coordination compounds, which can show luminescence on coordination and therefore, these can detect other species acting as sensor. The photophysical properties of the transition metal complexes has also attracted the attention for their possible use as sensors. The lifetime methods are more advantageous for detection than intensity measurement methods, because lifetime is independent of source variation, photobleaching of the material to be detected and change in efficiency of the optical system. The use of luminescent transition metal complexes as sensors has been reported with the structural effects on pH response.

Ru(II) complexes showed luminescence from MLCT transition. In the study of such complexes, environmental and structural features affect the luminescence of the sensor. The most general environmental factor is the presence of oxygen, which can quench the excited state, and reduce the intensity and lifetime; both.

2.5.8 Photocatalysis

There is an urgent need to respond the environmental and energy crisis for the development of green and renewable energy. Photocatalysis is the emerging

technology to address both these important issues. Photocatalysis is the process, in which catalyst (semiconductor) absorbs photon and as a result, electrons in valence band are excited to the conduction band and holes are created in the valence band of the photocatalysts. This is called formation of generation of excitons ($e-h^+$ pair), and therefore, reduction and oxidation reactions are initiated. One of the major goals of the photocatalysis is to harness solar energy to drive the reaction with high efficiency and large scale production. The field of photocatalysis has attracted the attention of scientists all over the globe due to its immense potential and wide range of applications starting from the development of first artificial photosynthetic system, water splitting, energy conversion, CO_2 reduction, organic synthesis, wastewater treatment, optoelectronic devices and nanomaterial science. Photocatalysis is categorized in two types; heterogeneous and homogeneous photocatalysis.

Heterogeneous photocatalysis is widely used due to easy separation of catalyst from the reaction mixture, applicability in chemical industries and stable photoactivity of the catalyst making them recyclable. However, homogeneous photocatalysis has also attracted great deal of attention due to their higher activity; selectivity and tunable light absorption. Therefore, if the advantages of both; homogeneous and heterogeneous photocatalysis can be combined, then more output is expected and for that the coordination chemistry can act as the bridge between them. The coordination compounds have been used in photocatalytic processes to engineer catalytically active sites tuning the band gap of photocatalysts (to bring it in visible region to harness solar energy), charge transfer kinetics and checking the phenomena of recombination of charge carriers, etc.

The photocatalysis can be graphically represented as (Fig. 2.9).

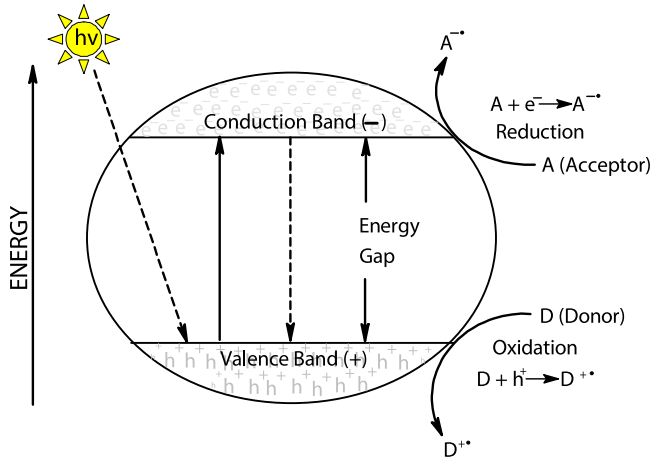

FIG. 2.9 Mechanism of photocatalysis.

Using photochemistry of coordination compounds, homogeneous photocatalyst has seen a vast increase in its horizon and the benefits of homogeneous photocatalysis are utilized in upgrading the heterogeneous catalysis. The demerits of heterogeneous photocatalysis is mainly less absorption of light due to wide band gaps, insufficient charge separation & transport, and lack of effective catalytic sites on the surface of semiconductor, but in homogeneous photocatalysis, ideal light harvesting centers and catalytic active sites are present. The Ru complex−g−C_3N_4 hybrid photocatalysts have been used for photocatalytic reduction of CO_2. The Ru(II) and Re(I) complexes have been widely investigated as photocatalyst for CO_2 reduction.

The use of metal complexes as photocatalysts for polymerization in presence of visible light has also been reported. When the complexes are excited by visible light, MLCT transition is there and therefore, these complexes easily adopt both; oxidation and reduction quenching modes, which can be utilized for synthetic organic reactions. The photophysical properties of these complexes can be tuned for the desired purpose by modifying the ligand scaffolds. Among the transition metals, first row transition metals particularly, copper complexes have attracted special attention for their use as photocatalysts; however, the copper−based photocatalysts are generally less efficient due to limited luminescence lifetime than Ru and Ir complexes, but copper complexes have been successfully used for organic transformations.

The photocatalysts using metal complexes consist of much diverse reactions induced by light as compared to organics. In organic photochemistry, there are only three states: S_0, S_1 and T_1 in general, but the photochemistry of transition metal complexes in quite different from the organic compounds in term of formation of more number of excited states with different multiplicities. So depending on the wavelength of irradiation, different kinds of electrically excited states are observed. This will cause population of excited states of varied reactivity. This situation provides good opportunity to tune the photochemical reactivity for switching over other various reaction pathways such as electron transfer due to population of diverse CT state substitution, disassociation, rearrangement reactions (due to excited LF states) and ligand centered conversion (due to population of IL$*$ states), etc. The electronic excitation by light can be used to generate coordinatively unsaturated species, complexes with altered oxidation number, free ligands and ligand redox products. Almost all such species are very reactive and found place to be utilized for photocatalytic reactions. Therefore, photocatalysis using transition metal complexes has gained applicable status in the research fields.

2.5.9 Nano-scale devices and machines

The field of photochemistry of coordination compounds had a very long journey in its progress and development of conceptual framework and its use in a wide range of applications. Starting from photography and light sensitivity

of metal complexes, it has now reached to construction of nano-scale devices and machines. This progress is spectacular due to expanded horizons of photoreactivity of coordination compounds. In earlier work, photosubstitution and photoredox reactions using simple inorganic ligands, quantum yields and life time studies, use of these complexes in biomolecular processes, energy and electron transfer were the main focus of investigations but with the advent of supramolecular chemistry, the photochemistry of coordination compounds has led to the design and construction of new systems, which can perform various light induced functions. In this area, luminescent and/or photoredox reactive metal complexes are in use as necessary components to construct the molecular devices and machines using bottom-up approach. In the light−powdered nanoscale devices, molecular wires based on coordination compounds containing polypiridine metal complexes as donor and acceptor units have been investigated. The excited state of $[Ru(bpy)_3]^{2+}$ acts as energy donor or redox reagent in many systems. In molecular wires, the photoinduced electron and energy transfer over long distances have been investigated. Similarly, molecular switches, in which energy transfer is very efficient due to favorable position of MLCT excited state of the complex and other bridging moiety. Molecular antennas for harnessing light energy using coordination compounds are also a fascinating area. Antenna systems are being used by nature also in photosynthetic process, where the light energy is converted to chemical energy. The collection of light energy by antenna may be used for increasing in signal intensity for luminescence and sensors. Supramolecules play a key role in the antenna effect.

Light powered nanoscale machines have also been investigated using coordination compounds metal complexes like dethreading or rethreading of pseudorotaxanes, shuttling processes in rotaxanes, ring switching process in catenanes, etc. and these are of much significance for their applications in opto−electronics and data information technology.

The research filed of photochemistry of coordination compounds is mainly based on intramolecular photochemical reactions to identify the photostable luminescent compounds and their utility in energy/electron transfer. Incorporating these coordination compounds in supramolecular systems and use of coordination compounds is an essential part of the bottom up approach to construct light powered nanoscale devices and machines. The $[Ru(bpy)_3]^{2+}$ complex has been very largely investigated in this regard. Looking to the spectacular progress of this field, the community of coordination chemists can hope to design and construct new families of coordination compounds for the furtherance of nanoscience and nanotechnology in near future.

Coordination compounds of titanium, zirconium and hafnium

Neetu Shorgar[1], **Priyanka Jhalora**[1], **Khushbu Sharma**[2] **and Shubang Vyas**[1]

[1]*Department of Chemistry, PAHER University, Udaipur, Rajasthan, India;* [2]*Department of Chemistry, B. N. University, Udaipur, Rajasthan, India*

3.1 Introduction

Group 4 elements titanium (Ti), zirconium (Zr), and hafnium (Hf) have outermost electronic configuration as $(n-1)d^2\ ns^2$ and these exist mostly in +4 oxidation state. They form coordination compounds in this state. Some of these complexes exhibited luminescent behavior mostly due to metal-to-ligand charge transfer. There is a great potential in such complexes for their use as photosensitizer, sensor, solar cells, imaging microscopy, light emitting diodes, and photocatalytic generation of hydrogen from water and also in degradation of wastewater containing different organic contaminants. There is also scope for use of these complexes in photodynamic therapy, particularly hafnium complexes.

3.2 Coordination compounds of titanium

Titanium is a chemical element with the symbol Ti and atomic number 22. It belongs to group 4 and its electronic configuration is [Ar] 3 d^2 $4s^2$. It is found in nature as an oxide, which can be reduced to produce a lustrous transition metal with a silver color, high strength, and low density. This element is also resistant to corrosion in sea water, aqua regia, and chlorine. Titanium is the ninth-most abundant element in Earth's crust about 0.63% by mass and the seventh-most abundant metal. The common minerals of titanium are anatase, rutile, brookite, perovskite, ilmenite, and titanite (sphene). Titanium was discovered in 1791 by an amateur geologist Reverend William Gregor. He found a black magnetic sand, which was a mixture of titanium and iron. Titanium has high strength-to-weight ratio. It is a strong metal (metallic-white in color) with low density, very ductile and lustrous.

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00006-X

Its +4 oxidation state is quite common but compounds in the +3 oxidation state are also sufficient in number. Generally, titanium has an octahedral geometry in its complexes, with tetrahedral ($TiCl_4$) is an exception.

The photochemistry of $TpTiCl_3$ and Tp^*TiCl_3 (where Tp = hydrotris(pyrazol-1-yl)borate) and Tp* = hydrotris(3,5-dimethylpyrazol-1-yl)borate) was studied by Gazzi et al. (2005) in tetrahydrofuran. It was observed that reactive decay of excited states produced either $HBpz_3^{\bullet}$ (or $HBpz_3^{\bullet *}$) and metal center Ti(III) radicals through homolytic cleavage of Tp → Ti (Tp* → Ti) bond.

The synthesis, photophysical properties and fluorescence quenching of four octa-substituted oxotitanium phthalocyanines were reported by Tau and Nyokong (2006). These are- 2,3,9,10,16,17,23,24-octaphenylthiophthalocyaninato titanium(IV) oxide, 2,3,9,10,16,17,23,24-octaphenoxyphthalocyaninato titanium(IV) oxide, 2,3,9,10,16,17,23,24-{octakis[(4-benzyloxy)phenoxy]phthalocyaninato}titanium(IV) oxide and 2,3,9,10,16,17,23,24-[octakis(4-t-butylphenoxyphthalocyaninato)]titanium(IV) oxide. It was reported that moderate fluorescence quantum yields (0.14−0.19) and lifetimes were there. It was also revealed that good triplet quantum yields were obtained, while triplet lifetimes (40−100 μs) were quite short.

Atilla et al. (2007) reported synthesis, photophysical and photochemical properties of tetra- and chlorotetrapoly (oxyethylene)-substituted oxotitanium(IV) phthalocyanines. These complexes were found to be monomeric in nature in solution. It was revealed that photophysical and photochemical properties of these phthalocyanine complexes may be very useful for photodynamic therapy applications. These complexes have potential as photosensitizer (in type II mechanism) of singlet oxygen, where quantum yields (Φ_Δ), were in the range 0.72 and 0.78.

The aryloxy and arylthio tetrasubstituted oxotitanium(IV) phthalocyanine complexes were used by Tau and Nyokong (2007) for the oxidation of 1-hexene in dichloromethane as photocatalyst. It was observed that 1,2-epoxy hexane and 1-hexen-3-ol were found to be the major and minor products, respectively. The photooxidation followed two reaction pathways: (i) Singlet oxygen (Type II) and (ii) Radical (Type I) reaction. Oxidation of 1-hexene also depends on singlet oxygen quantum yields and photostabilities of the phthalocyanines.

The photophysical and photosensitizing properties of two octacationic oxotitanium phthalocyanines (TiOPcs) (bearing pyridiniomethyl or cholinyl substituents) were reported by Kuznetsova et al. (2009). Both these compounds were found monomeric in water with high quantum yields of singlet oxygen formation ($\Phi_\Delta = 0.4-0.5$) and fluorescence ($\Phi_F = 0.17-0.19$). It was found that aqueous TiOPc solutions and produced hydroxyl radicals under illumination, which may be due to photocleavage of water molecules. Photobleaching of TiOPcs was also observed on irradiation of TiOPc solutions and its quantum yield in water was found to be about 1×10^{-4}. It was revealed that both; OH and $^1O_2$ may be responsible for the bactericidal effects of TiOPcs.

Erdoğmuş et al. (2010) reported syntheses of peripherally tetra-, non-peripherally tetra and peripherally octa-3,4-(methylendioxy)-phenoxy substituted oxo-titanium(IV) phthalocyanine complexes. It was found that all these oxo-titanium(IV) phthalocyanine complexes were soluble in organic solvents. They also investigated photophysical and photochemical properties of oxo-titanium(IV) phthalocyanine complexes in DMSO as well as toluene. The effects of the position of the substituents on the phthalocyanine skeleton and solvents (DMSO and toluene) were also observed on photophysical and photochemical parameters of the oxo-titanium(IV) phthalocyanine complexes.

Hu and Tao (2011) developed an optical fiber sensor technique for determining trace amount of H_2O_2 in aqueous solutions. They used a titanium(IV) oxyacetylacetonate doped Nafion coating on the surface of a bent optical fiber probe as a transducer. Here, trace amount of H_2O_2 in an aqueous solution diffused into the polymer coating reacted with the sensing agent. The product obtained absorbs light (wavelength 360 nm). It was revealed that this sensor reversibly responses to trace H_2O_2 in water with detection limit (3σ) as 7.4×10^{-8} mol H_2O_2 L^{-1}. It was interesting to note that this fiber-optic sensor does not have interference from electromagnetic field making it useful in proton exchange membrane for fuel cells. Although high-valence Ti(IV)-based metallocalixarene coordination cages (linked by oriented ancillary ligands) are not known and therefore, tunable calixarene-based coordination cages of Ti(IV) with a framework formula $[Ti_{12}(O^iPr)_{12}(TBC[4])_6L_6]$ were assembled from six pyridinedicarboxylic ligands and six $\{Ti_2(O^iPr)_2(TBC[4])\}^{2+}$ nodes. These as-prepared $\{Ti_{12}L_6\}$ cage displayed strong photocatalytic activity for H_2 evolution.

Chauke et al. (2011) reported the synthesis of 2,(3) (peripheral) and 1,(4) (non-peripheral) (2-mercaptopyridine) phthalocyanine complexes of titanium(IV) oxide. They studied photocatalytic oxidation of cyclohexene in the presence of gold nanoparticles (AuNPs). It was observed that singlet oxygen quantum yield values were increased in the presence of AuNPs for these complexes and percentage conversion was 27% and 20%, respectively. Cyclohexene oxide, 2-cyclohexen-1-ol, 2-cyclohexene-1-one and 1, 2-cyclohexanediol were obtained as the products.

Liu et al. (2016a) reported a new cadmium doped titanium−oxo complex with a $\{Cd_2Ti_4\}$ cluster core, which was stabilized by tert-butylacetic acid ligands. It was observed that this new 75 heterometallic cluster is a semiconductor, which has a bandgap of 3.39 eV. It also exhibited good photocatalytic activity and stability for evolution of hydrogen. It was claimed that transition metal doped polyoxotitanium compounds have a potential for the development of efficient water splitting photocatalysts.

He et al. (2018) prepared palladium-directed self-assembly of multi-porphyrin array ultrathin films on substrate surfaces. They used sodium tetrachloropalladate (Na_2PdCl_4) as a connector and oxo[5,10,15,20-tetra(4-pyridyl)porphyrinato] titanium(IV) complex [TiO(TPyP)] as a linker. It was

reported that Soret absorption band of TiOTPyP was red shifted by 6 nm, when the Pd-TiOTPyP multilayer-modified quartz substrate was immersed in an aqueous solution of hydrogen peroxide. This shift may be due to the formation of TiO_2TPyP monoperoxo complex. It was revealed that immobilized Pd-TiOTPyP multilayers act as light-harvesting units for generation of photocurrent and photochromism of viologens, which has strong stability, recyclability, and reproducibility. It was also found that photocurrent density was enhanced in electrolyte solutions, which contain electron donors (triethanolamine), or electron acceptors (viologens). They also investigated photoinduced reduction (photochromism) of viologens using EDTA as the electron donors and Pd-TiOTPyP multilayers as light sensitizers.

Hydrothermal syntheses is normally used in the area of polyoxometalates and metal organic frameworks, but hydrothermal synthesis of crystalline titanium(IV) complexes is an exciting challenge, because of high reactivity and spontaneous hydrolysis of titanium(IV) ions, which leads to rapid precipitation of oxide rather crystalline compounds. Dong et al. (2018) reported an effective route to synthesize crystalline titanium(IV) complexes and three titanium(IV) compounds were isolated in the presence of organic amines. It is intresting to note that organic amines played an important role in the synthesis and introduction of chromophores increased the visible light harvesting.

Janek et al. (2018) synthesized titanium oxo-clusters composed of $\{Ti_4O_2\}$ and $\{Ti_6O_6\}$ cores by from the direct reaction of $Ti(O^iBu)_4$ and 4-aminobenzoic acid (HABZ) in different molar ratios (4:1, 2:1, and 1:1) at room temperature. The complex $[Ti_4O_2(O^iBu)_{10}(ABZ)_2]$ 0.7^iBuOH $0.5C_7H_8$ was isolated from the reaction mixture having molar ration (4:1); however, slow evaporation of in situ alcohol; however, led to the formation of complex $[Ti_4O_2(O^iBu)_{10}(ABZ)_2]$. The formation of other two complexes $[Ti_4O_2(O^i\text{-}Bu)_{10}(ABZ)_2]$ and $[Ti_6O_6(O^iBu)_6(ABZ)_6]$ was separated by 2:1, and 1:1 mother liquor, respectively. The photocatalytic activity of these composite foils produced by dispersion of second complex in the polystyrene matrix was evaluated by the photodegradation of the methylene blue in presence of UV light irradiation.

The first Ti_8L_{12} cube was assembled by Zhu et al. (2018a) that could further encapsulate an $[Ti(H_2O)_6]$ species. It was observed that host−guest hydrogen-bonding interactions in $[Ti(H_2O)_6]@Ti_8L_{12}$ resulted in different behavior in photophysical properties, luminescent bands, redshifted absorption, longer excited-state lifetime, and larger photocurrents. Titanium-based coordination cages are interesting species for both; photophysical and supramolecular chemistry. The $[Ti(H_2O)_6]@Ti_8L_{12}$ complex is stable in both; as well as solution and solid states, the photodynamics of both; free as well as $[Ti(H_2O)_6]$ guest encapsulated Ti_8L_{12} cube was confirmed.

Zhu et al. (2018b) reported the synthesis of two salicylate-stabilized polyoxo-titanium clusters (PTCs) with as well as without fluorine. These are $H_2[Ti_{13}(\mu_3\text{-}O)_7(\mu_2\text{-}O)_4(Sal\text{-}F)_9(O^iPr)_{14}]$ (PTC-95), (where $H_2Sal\text{-}F = 5\text{-flu}$

orosalicylic acid) and $H_2[Ti_{14}(\mu_3\text{-}O)_8(\mu_2\text{-}O)_4(Sal)_8(O^iPr)_{18}]\cdot HO^iPr$ (PTC-96), (where H_2Sal = salicylic acid). It was indicated that PTC-95 had a compact structure, which is made up of a quadrangular prism with an appended linear Ti_3 cluster and two additional Ti atoms, while PTC-96 has an arch bridge-shaped structure, which is linked by two Ti_4 $(\mu_3\text{-}O)_2$ and two $Ti_3(\mu_3\text{-}O)$ clusters. It was also revealed that these clusters exhibited diverse photocurrent response properties and photocatalytic activities toward dye degradation.

Janek et al. (2019) synthesized titanium(IV) oxo-complexes (TOCs) of the general formula $[Ti_3O(O^iPr)_8(OOCR')_2]$ (where $R' = -C_{13}H_9$, -*p*-PhCl, -*m*-$PhNO_2$, and $-C_4H_7$). They used different carboxylate ligands for changing optical band gaps of the as-prepared microcrystals. It was reported that dispersion of TOCs in the poly(methyl methacrylate) matrix (PMMA) resulted in polymer/TOCs composites, which can be applied for estimation of photocatalytic activity of as-synthesized trinuclear Ti(IV) oxo-complexes. Photocatalytic degradation of methylene blue was used as the model system in prescence of UV irradiation.

The synthesis of two new polyoxo−titanium cluster complexes with thiacalix[4]arene ligands was reported by Wang et al. (2020). It was revealed that there were two distinctly different conformations of core-protecting ligands, i.e., 1,2-alternate and cone in the tetranuclear Ti4 and the hexanuclear Ti6 complexes. Such ligand−cluster core coordination not only extended absorption edge of these complexes in visible-light region but it also increased their stability in the photocatalytic process for evolution of hydrogen. It was also indicated that calixarene conformation significantly affected the visible-light photocatalytic performances of such clusters. It was revealed that incorporation of S and suitable titanium coordination geometry may be responsible for the photocatalytic activities.

It is known that construction of three-dimensional (3D) covalent organic frameworks (COFs) is an exciting challenge due to the limited types of organic building blocks. Lu et al. (2021) prepared a 3D anionic titanium-based COF (Ti−COF-1) with an edge-transitive (6, 4)-connected soc topology with octahedral Ti^{IV} complex as the building unit. It was reported that Ti−COF-1 exhibited superior stability, high crystallinity, and large specific surface area (1000.4 $m^2\ g^{-1}$). It was revealed that this COF has a broad absorption band with band gap of 1.86 eV, and it exhibited high photocatalytic activity toward Meerwein addition reactions.

Kubiak et al. (2021) produced composite materials by the dispersion of titanium(IV)-oxo complexes (TOCs) in poly(ε-caprolactone) (PCL) matrix with the $[Ti_4O_2(O^iBu)_{10}(O_2CR')_2]$ (where $R' = PhNH_2$ and $C_{13}H_9$) by direct reaction of titanium(IV) isobutoxide with 9-fluorenecarboxylic acid or 4-aminobenzoic acid. As a result, the composites PCL + *n*TOCs ($n = 5$ and 20 wt.%) was produced. It was revealed that as-prepared PCL + TOCs composites, exhibited higher photocatalytic activity in the visible range.

Lebedkin et al. (2021) investigated optical properties of four trinuclear chalcogenolato bridged metal complexes $[Ag_2Ti(SPh)_6(PPh_3)_2]$, $[Na(thf)_3]_2[Ti(SPh)_6]$, $[Cu_2Ti(SePh)_6(PPh_3)_2]$, and $[Ag_2Ti(SePh)_6(PPh_3)_2]$. All of these complexes displayed efficient near-infrared luminescence at ~880−1200 nm at low temperatures in the solid state. It is quite intense in case of $[Cu_2Ti(EPh)_6(PPh_3)_2]$, (E = S, Se) at ambient temperature and exhibited PL quantum yields of 9.5% and 4.8% at $\lambda_{PL} = 1090$ and 1240 nm, respectively. It was reported that lowest-energy electronic transitions in these complexes is due to their high localization on the metal and chalcogen atoms, with almost negligible contributions of the external ligand groups.

Mou et al. (2021) synthesized tartrate-stabilized titanium−oxo clusters with sulfonate chromophore ligands, $Ti_4(C_4H_2O_6)(AS)_2(O^iPr)_{10}$ and $Ti_4(C_4H_2O_6)(ATS)_2(O^iPr)_{10}$ (where $C_4H_2O_6$ = tartrate, AS = aniline-2-sulfonate, and ATS = 4-aminotoluene-3-sulfonate). It was indicated that these crystals are a class of small TOCs, which contain only four titanium atoms in the asymmetric unit, and formed a centrosymmetric planar square $\{Ti_4\}$ core. This core was chelated by a bridging hexadentate tartrate ligand in *trans*-orientation. These TOCs have band gaps of 3.16 and 2.95 eV, respectively. Their photocurrent response and the photocatalytic activity for degrading methylene blue was also examined.

The d^0 complexes with ligand-to-metal charge-transfer (LMCT) excited states represent a new series of photocatalysts. London et al. (2021) studied photochemistry and photophysics of d^0 titanocenes, $Cp_2Ti(C_2R)_2$, [where C_2R = ethynylphenyl (C_2Ph), 4-ethynyldimethylaniline (C_2DMA), or 4-ethynyltriphenylamine (C_2TPA)]. It was found that two aryl rings in $Cp_2Ti(C_2DMA)_2$ are nearly face-to-face in the solid state, while these are mutually perpendicular in $Cp_2Ti(C_2Ph)_2$. All these three complexes are highly emissive at 77 K, but they undergo photodecomposition at room temperature on irradiation into their lowest-energy absorption bands. They found that emission wavelengths and photodecomposition quantum yields of these complexes are: $Cp_2Ti(C_2Ph)_2$, (575 nm and 0.65), $Cp_2Ti(C_2TPA)_2$, (642 nm and 0.42), and $Cp_2Ti(C_2DMA)_2$ (672 nm and 0.25). It was reported that computational data are in favor of emission from a ^{3}LMCT state, which is indicated by compression of the C−Ti−C bond angle as evident from ^{3}LMCT state, which is consistent with the known products of photodecomposition.

Wang et al. (2021) synthesized three lanthanide-doped titanium−oxo clusters (Ln-TOCs): $[Ti_4La(\mu_3\text{-}O)_3(O^iPr)_2(C_6H_5COO)_{11}]\cdot 3CH_3CN$, $[Ti_4Eu_2(\mu_3\text{-}O)_4(acac)_2(C_6H_5COO)_{13}]$, (where acac = acetylacetonate), and $[Ti_7Ce(\mu_2\text{-}O)_2(\mu_3\text{-}O)_5(O^iPr)_2(C_6H_5COO)_{15}]\cdot CH_3CN$. It was reported that these Ln−TOCs displayed strong UV-light absorption with extended visible light absorption, may be due to doping of lanthanides and benzoates. The Ln doped clusters exhibited good photocurrent responses. Particularly, third cluster showed highest photocurrent intensity, because of Ce(IV)/Ce(III) redox reaction.

London et al. (2022) synthesized nine titanocene complexes, $Cp_2Ti(C_2Ar)_2 \cdot MX$ (where Ar = phenyl, dimethylaniline, triphenylamine; and MX = CuCl, CuBr, or AgCl). It was reported that MX coordinates to alkyne tweezers and CuX coordination has more structural impact than AgCl. All these complexes are brightly emissive at 77 K (emission max between 575 and 767 nm), but with coordination of MX, the emission was redshifted. It was observed that parent complexes photodecomposed at room-temperature solution with quantum yields, Φ_{rxn}, ranging between 0.25 and 0.99. A clear trend was there that the emission energy increases with increase in Φ_{rxn}.

Śmigiel et al. (2022) synthesized oxo complex $[Ti_4O_2(O^iBu)_{10}(asp)_2] \cdot H_2O$ by reaction of titanium(IV) isobutoxide and acetylsalicylic acid (Hasp) in 4:1 M ratio. They also studied photocatalytic activity of as-synthesized complex using composite foils produced by the dispersion of micrograins, as the inorganic blocks, in a polycaprolactone (PCL) matrix. It was observed that on absorption maximum wavelength shifted to 425−450 nm on introduction of micrograins to the PCL matrix. This composite samples exhibited good activity toward photodecolorization of methylene blue in prescence of visible light.

3.3 Coordination compounds of zirconium

Precious stones containing zirconium, such as hyacinth and zircon, have been used as decorations since ancient times. Zirconium was recognized as an element by Martin Heinrich Klaproth (1789), and Jacob Berzelius (1824), was able to produce zirconium as an amorphous black powder. This element was given its name by Persian word 'zargon', which means gold-like. Zirconium is belongs to group 4 and its electronic configuration is [Kr] 4 d^2 $5s^2$. In general, zirconium compounds are colorless and diamagnetic in nature with the oxidation state as +4; of course, a few. Zr(III) compounds are known, but Zr(II) is very rare. Zirconium forms a wide range of coordination complexes.

Loukova and Smirnov (2000) reported long-lived ligand-to-metal charge transfer (LMCT) excited states based on zirconium and hafnium complexes using $Cp_2Zr(IV)Cl_2$ and $Cp_2Hf(IV)Cl_2$. The lifetime of these complexes was of the order of 2000 and 300 μs, respectively. The phosphorescence spectra, quantum yields and lifetimes in these metallocenes $Cp_2M(IV)Cl_2$ was discussed in light of the nature of the metal (Ti, Zr or Hf)−ligand π-bonding character.

Kunkely and Voglev (2004) reported a complex ethylenebis(indenyl)zirconium(IV) binolate (where = binol (1,1′-binaphthyl-2,2′-diol) exhibited lowest-energy ππ* binolate intraligand (IL) excited state with absorption peak at $\lambda_{max} = 348$ nm. It was also revealed that this IL triplet undergoes an emission at $\lambda_{max} = 490$ nm.

Gerasymchuk et al. (2005) incorporated Zr(IV) and Hf(IV) phthalocyanines with gallate as axial ligand coordinated to the central metal atom of

phthalocyanine in silica gels via sol−gel process. They used tetraethyl orthosilicate (TEOS) as a precursor. It was reported that as-obtained mixed inorganic−organic composites were homogeneous and transparent. An intensive fluorescence emission (700−725 nm) was observed upon long-wavelength excitation and much larger Stokes shift (about 45 nm) in the Q region, suggesting that Zr(IV) and Hf(IV) phthalocyanines could be used as photosensitizers in the photodynamic therapy.

The luminescent properties of mixed-ligand complexes of zirconium(IV) and hafnium(IV) phthalocyaninates with 4-benzoyl-3-methyl-1-phenyl-2-pyrazolin-5-one were investigated by Tret'yakova et al. (2006) in different organic solvents. They have determined quantum yields of fluorescence lifetimes of the excited states, and the molar extinction coefficients for these complexes.

Zirconium(IV) and hafnium(IV) phthalocyanines were synthesized with various carboxylic acids as out-planed ligands using an interaction between di(chloro)zirconium(IV)- or hafnium(IV)-phthalocyanines and carboxylic acids (Tret'yakova et al., 2007). They have indicated coordination of two acid fragments in a *cis*-geometry about the central atom of the macrocycle. These compounds were found non-aggregated in the organic solvents. They have also evaluated fluorescence quantum yields (Φ_F) and natural lifetimes (τ) of zirconium phthalocyanine complexes in toluene and DMSO.

Some zirconium(IV) and hafnium(IV) phthalocyanines were also prepared by Tomachynski et al. (2008) with various β-dicarbonyl ligands through direct interaction between di(chloro)zirconium(IV) or hafnium(IV) phthalocyanines and free β-diketones 4-benzoyl-3-methyl-1-phenyl-2-pyrazolin-5-one. Fluorescence quantum yields (Φ_F) and natural life times (τ) of zirconium phthalocyanine complexes were also determined in different solvents such as DMSO, toluene, and THF.

Kathirgamanathan et al. (2011) synthesized two new phases of zirconium tetrakis(8-hydroxyquinolinolate) (Zrq_4). It was observed that these two phases have remarkable differences in their performance in organic light emitting devices. It was revealed that α-Zrq_4 has lower operating voltage, longer lifetime and higher efficiencies as compared to β-Zrq_4 in organic light emitting devices.

It was reported by Loukova et al. (2012) that spectral-luminescent properties (phosphorescent) of organometallic complexes of Ti, Zr, and Hf with aromatic ligands are due to ligand-to-metal charge transfer (LMCT) states. It was revealed that there was a linear dependence of the phosphorescent characteristics of zirconocene on nature of coordinative (inner- and outersphere) interactions of the phosphorescent metal complex with media molecules and molecular structure of organic media.

Radivojevic et al. (2012) evaluated Zr(IV) and Hf(IV) complexes of 5,10,15,20-tetraphenylporphyrin (TPP) and metallophthalocyanine (Pc) as dyes for the dye-sensitized solar cells. It was observed that Zr(IV)

phthalocyanine dye performed better in DSSCs, as compared to Zr(IV) porphyrin with an overall efficiency of ~1.0% while Hf(IV) complexes were found to be less efficient. It was found that photophysical properties of these complexes in solution are responsible for energetically favorable injection of electrons into the conduction band of TiO_2 nanoparticles, as well as good band gap match with I_3^-/I^-pair in ionic liquid, 1-butyl-3-methyl imidazolium iodide. It was reported that a combination of TPP (blue absorbing) with the Pc complexes (red absorbing) can enhance absorbance of solar light in the DSSCs.

Shahroosvand et al. (2012) synthesized zirconium complexes using a mixture of zirconium nitrate, potassium thiocyanate, 1,2,4,5-benzene tetracarboxylic acid (H_4btec), and 1,10-phenanthroline (phen). It was reported that photoluminescence emission of seven zirconium complexes exhibited two series of peaks: (i) Sharp and intense bands from 300 to 500 nm and (ii) Broadened with less intensity from 650 to 750 nm. The PVK:PBD blend was used as a host for doping of zirconium compounds and ratio of zirconium complexes were modified by 8 wt.% in PVK:PBD(100:40).

Pritchard et al. (2013) prepared zirconium and hafnium metallocene dihalides based on simple polyphenyl cyclopentadienes. These were found to be stable at room-temperature and can act as lumophores with large Stokes shifts, emitting from states with sufficient LMCT character. It was also indicated that these species have a potential as lumophores for fluorescence cell-imaging microscopy.

Shahroosvand et al. (2013) synthesized eight new zirconium complexes using 1,2,4,5-benzenetetracarboxylic acid (H_4btec), 1,10-phenanthroline (phen) and 4,7-diphenyl−1,10-phenanthroline (Bphen), as ligands. They used these as light emitting material in fabricated organic light emitting diodes (OLEDs). A yellow−green photoluminescence (PL) emission was observed with a red shift compared to the PVK:PBD blend. It was reported that devices with Zr complexes (ITO/PEDOT:PSS/PVK:PBD/zirconium complex/Al) emitted a yellow−red light.

Some zirconium-carboxylate metallocavitands were prepared by Iden et al. (2014) $[(CpZr)_3(\mu\text{-}\kappa_2,O',O''CR)_3(\mu_3\text{-}O)(\mu_2\text{-}OH)_3]Cl$ (where Cp = cyclopentadienyl; R = C_5H_4N, C_6H_7N, $C_{18}H_{14}N$ and $C_{18}H_{12}N$) with moderate to high yields (40%−83%). The carboxylic acids was treated with Cp_2ZrCl_2 at room temperature for this purpose. It was reported that two complexes exhibited efficient photoluminescence properties in solution with a peak at 464 and 422 nm and quantum yields as 87% and 65% in solution, respectively.

Guo et al. (2015) reported a broad-band direct white-light emission, which was originated from a single-phased and single-doped phosphor luminescent mesoporous zirconium oxy-hydroxy acetate−persulfate complex and Eu^{3+}-doped complex. It was also observed that amorphous complexes exhibited the photoluminescence and color properties. It was interesting to note that a white-light emission is from the single-phased and single-doped phosphors, which

were prepared via low-cost chemical approach. The pristine complex has been used as a precursor of environmentally benign catalysts in the esterification of lauric acid with methanol and in n-hexane isomerization.

Bestgen et al. (2016) synthesized phosphine-functionalized zirconocene derivatives as metalloligands. The reactivity and photoluminescent properties of methylzirconocene phosphines were also investigated. It was reported that some of the compounds show bright emission with quantum yields of up to 19% even at room temperature on excitation at 350 nm.

Zhang et al. (2016) synthesized titanium and zirconium complexes using two 2,6-bis(pyrrolyl)pyridine ligands. It was reported that neutral complexes Ti(^{Me}PDP)$_2$ and Zr(^{Me}PDP)$_2$ (where ^{Me}PDP = 2,6-bis(5-methyl-3-phenyl-1H-pyrrol-2-yl)pyridine) exhibited intense ligand-to-metal charge-transfer (LMCT) bands in the visible range. They undergo reversible redox reactions under highly reducing conditions. It was also observed that Zr(^{Me}PDP)$_2$ is photoluminescent in nature and its excited state can be quenched even by mild reducing agents to generate a powerful electron transfer reagent. It can enhance dehalogenation reactions, reduction of olefins (electron-poor) and the reductive coupling of benzyl bromide via photoredox catalysis (Fig. 3.1). It was also claimed by them that the earth-abundant metal complex like Zr(^{Me}PDP)$_2$ can be used an alternative to costly metal photosensitizer such as $[Ru(bpy)_3]^{2+}$.

Zhang et al. (2018) prepared these compounds have long-lived excited states on exposure to visible light, which resulted in phosphorescent emission with relatively higher lifetimes (microsecond range) and luminescence quantum yields of 3% and 18% for Zr(HCNN)$_2$, and Zr(MeCNN)$_2$, respectively in benzene solution at room temperature. It was revealed that IL transitions with

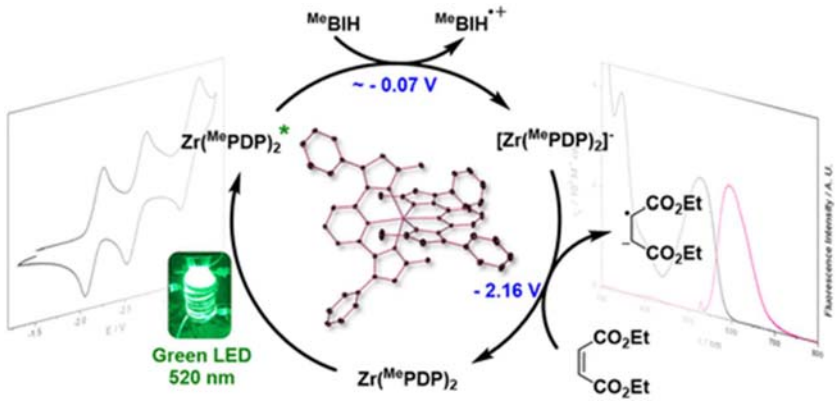

FIG. 3.1 Use of zirconium complexes in reduction of olefins. *Adapted from Zhang, Y., Petersen, J.L., Milsmann, C., 2016. A luminescent zirconium (IV) complex as a molecular photosensitizer for visible light photoredox catalysis. J. Amer. Chem. Soc. 138 (40), 13115−13118. With Permission.*

significant LMCT character of 20%−30% was there. The photochemical reactivity of $Zr(MeCNN)_2$ is photoinduced outersphere electron transfer, which enabled it in photoredox catalysis, while $Zr(HCNN)_2$ undergoes C−C reductive elimination upon photoexcitation with mild oxidants resulting in the formation of $Zr(DPDP)X_2$ (where X = Br or SBn) complexes (Fig. 3.2). It was attributed to the absene of methyl group adjacent to Zr−C bond.

Low et al. (2018) synthesized and investigated the reactivity of Zr complexes supported by a 9,10-anthracenediyl-linked bisphenoxide ligand (L). It was reported that $Zr^{IV}LBn_2$ undergoes photolytic reduction with formation of bibenzyl and $Zr^{IV}L(THF)_3$, which displayed a two-electron reduced anthracene moiety. It was reported that leveraging ligand-stored reducing equivalents promoted the oxidative coupling of internal and terminal alkynes both to zirconacyclopentadiene complexes, which suggested that anthracene can be used as a redox reservoir reversibly.

Some new heteroleptic zirconium and hafnium complexes were synthesized by Kuhlmann et al. (2018a). Different substituted phenoxy benzoxazoles (where HL1 = 2-(2′-hydroxyphenyl)benzoxazole, HL2 = 2-(2′-hydroxynaphthyl)benzoxa-zole, and HL3 = 2-(2′-hydroxy-3′,5′-di-tert-butylphenyl) benzoxazole) were used as ligands along with chloride in these complexes. Their crystals showed distorted octahedral or capped trigonal prismatic coordination spheres. It was reported that a fluorescence was there from short-lived excited state and emission maxima was observed in the blue region.

Sun et al. (2018) synthesized a porous and visible light responsive zirconium metal−organic framework ($[Zr_6O_4(OH)_4(L)_6]\cdot 8DMF$ (Zr-SDCA-NH_2). They used a conjugated amine-functionalized dicarboxylic ligand (where H_2L = 2,2′-diamino-4,4′-stilbenedicarboxylic acid; H_2SDCA-NH_2). It was reported that Zr-SDCA-NH_2 exhibited visible-light activity for CO_2 reduction, when used as a photocatalyst. The formate formation rate of 96.2 μmol h^{-1} $mmol^{-1}_{MOF}$ could be achieved, which is higher than other

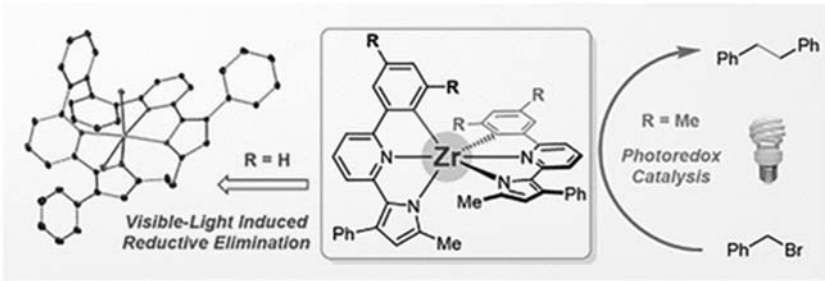

FIG. 3.2 Visible-light induced reductive elimination and photoredox catalysis by zirconium complexes. *Adapted from Zhang, Y., Petersen, J.L., Milsmann, C., 2018 Photochemical C−C bond formation in luminescent zirconium complexes with CNN pincer ligands. Organometallics 37 (23), 4488−4499. With Permission.*

reported amine-functionalized Zr-MOFs. It was indicated that Zr_6 oxo-cluster contributed to the CO_2 photoreduction through the LMCT process and the organic ligand; both.

The extreme ultraviolet (EUV) photochemistry of metal oxoclusters based on Ti, Zr, and Hf with methacrylate ligands (Mc) and their sensitivity as resist materials was compared by Castellanos et al. (2018). The decarboxylation was observed upon EUV exposure in all these cases; however, higher sensitivity was reported for the Hf-based material as compared to Zr-based analogue. It was indicated that there was not a major loss of organic shell and high degree of aggregation of the naked inorganic cores, which are very much are required for this type of molecular thin film so that these can operate as a resist material.

Tahershamsi et al. (2019) synthesized two complexes of bis(amino-benzoato) zirconium(IV) phthalocyanine and their graphite oxide-based composites. These complexes generated reactive oxygen species (ROS) in presence of light. The photoactivity of as-prepared materials was compared for their potential in biomedical applications, such as photosensitizers in photo-dynamic therapy.

Zhang et al. (2019) synthesized luminescent seven-coordinated zirconium and hafnium complexes with three mono-anionic 2,2′-pyridylpyrrolide ligands and a chloride. A hybrid of ligand-to-metal charge transfer (LMCT)/ligand-to-ligand charge transfer (LLCT) was considered responsible for visible light absorption band. It was observed that complexes $(^{Me}PMP^{Me})_3MCl$ (where M = Zr, Hf, and $^{Me}PMP^{Me}$ = 3,5-dimethyl-2-(2-pyridyl)pyrrolide) were found emissive at room temperature in solution upon irradiation with visible light. It was due to a combination of fluorescence and phosphorescence, which are having excited state lifetimes in the low to sub-ns and μs timescale, respectively.

Salojärvi et al. (2020) synthesized some soluble and intensely near-IR-absorbing complexes of transition metal (where metal = Ti, Zr, V, and Ni). They used redox non-innocent *N*,*N*′-bis(3,5-di-tertbutyl-2-hydroxy-phenyl) −1,2-phenylenediamine (H_4L) as a ligand precursor. Two organic molecules were coordinated to the metal center as tri- or tetradentate ligands in these complexes ($[Ti\ (L^{ox})_2]$, $[Zr\ (L^{ox})_2]$, $[V(L^{sq1})(HL^{ox})]$ and $[Ni(HL^{ox})_2]$. These complexes were thermally stable. All compounds strongly absorb in the near-IR region.

Zhang et al. (2020a) prepared seven bis(pyridinedipyrrolide)zirconium complexes $Zr(^{R}{}_1PDP^{R}{}_2)_2$, (where $[^{R}{}_1PDP^{R}{}_2]^{2-}$ is the doubly deprotonated form of [2,6-bis(5-R_1-3-R_2-1*H*-pyrrol-2-yl)pyridine]). It was reported that all these complexes exhibited significant long emission lifetimes (τ = 190−576 μs) and high quantum efficiencies (Φ_{PL} = 0.10−0.38) under visible light in benzene. It was observed that substituents on the pyrrolide rings had significant effects on the electrochemical properties and photoluminescence of these compounds. It was revealed that R_2 substituents (where R_2 = H, Me, Ph, or C_6F_5) had only limited effects on the absorption as well as emission profiles of the complexes but it allowed tuning of the ground- and excited-state redox

potentials, while R_1 substituents (where $R_1 = H$, Me, Ph, or 2,4,6-Me_3Ph) influenced both; optical and electrochemical properties. The photoredox catalytic dehalogenation of aryl iodides and chlorides with $Zr(^{Me}PDP^{Me})_2$, showed a potential of $Zr(PDP)_2$ as-photosensitizer to enhance difficult reductive transformations upon excitation with green light and that too under mild conditions.

Zhang et al. (2020b) reported an air- and moisture-stable, visible light-absorbing Zr(IV) photosensitizer, Zr(MesPDPPh)2,(where $[^{Mes}PDP^{Ph}]^{2-}$ is the doubly deprotonated form of [2,6-bis(5-(2,4,6-trimethylphenyl)-3-phenyl-1*H*-pyrrol-2-yl)pyridine]). It was observed that this molecule has a long-lived triplet LMCT excited state ($\tau = 350$ μs) with highly efficient photoluminescence emission ($\Phi = 0.45$). This was attributed to thermally activated delayed fluorescence from the higher-lying singlet configuration with significant LMCT contributions. It was revealed that Zr(MesPDPPh)2 can be used in many photoredox catalytic processes and triplet energy transfer. This work provides a blueprint for development of photosensitizer in future with early transition metals and excited states with significant LMCT contributions.

Dunlop et al. (2021) prepared some metallocene complexes of cationic group 4 with pendant imine and pyridine donor groups as stable crystalline $[B(C_6F_5)_4]^-$ salts. These were obtained by: (i) Protonation of the intramolecularly bound ketimide moiety in neutral complexes $[(\eta^5\text{-}C_5Me_5)\{\eta^5\text{-}C_5H_4CMe_2CMe_2C(R)=N\text{-}\kappa N\}MCl]$ (where M = Ti, Zr, Hf and R = *t*-Bu, Ph) by $PhNMe_2H^+[B(C_6F_5)_4]^-$ to give $[(\eta^5\text{-}C_5Me_5)\{\eta^5\text{-}C_5H_4CMe_2CMe_2C(R)=NH\text{-}\kappa N\}MCl]^+[B(C_6F_5)_4]^-$ or (ii) Chloride ligand abstraction from the complexes $[(\eta^5\text{-}C_5Me_5)(\eta^5\text{-}C_5H_4CMe_2CH_2C_5H_4N)MCl_2]$ (where M = Ti, and Zr) by $Li[B(C_6F_5)_4]\cdot 2.5Et_2O$ to give $[(\eta^5\text{-}C_5Me_5)(\eta^5\text{-}C_5H_4CMe_2CH_2C_5H_4N\text{-}\kappa N)MCl]^+[B(C_6F_5)_4]^-$. It was observed that these cationic complexes of Zr and Hf, exhibited enhanced luminescenceas as compared to the corresponding neutral species. It was predominantly from triplet ligand-to-metal (^{3}LMCT) excited states with quantum yields up to 58% and lifetimes up to 62 μs in the solid state (Fig. 3.3).

3.4 Coordination compounds of hafnium

Hafnium is a chemical element with the symbol Hf and atomic number 72. Hafnium belongs to group 4 and its electronic configuration is [Xe] $4f^{14}$ 5 d^2 $6s^2$. It is lustrous, silvery gray, and tetravalent transition metal. It resembles chemically with zirconium and it is found in many zirconium minerals. Although, its existence was predicted by Dmitri Mendeleev in 1869, but it was identified in 1923 by Dirk Coster and George de Hevesy. Hafnium is named after Hafnia, which is a Latin name for Copenhagen. It is used in electrodes and filaments. Some superalloys are prepared for special applications, which contain hafnium along with niobium, titanium, or tungsten. It is corrosion-resistant also.

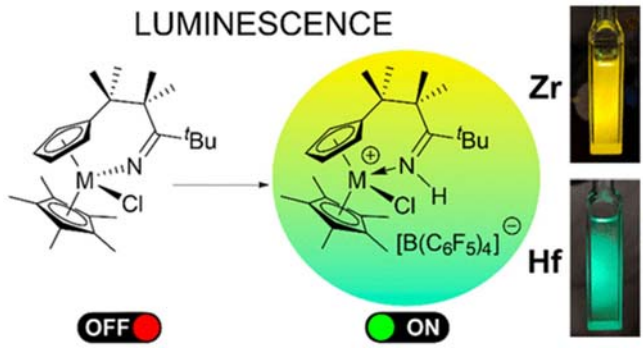

FIG. 3.3 Enhanced luminicence of cationic complex of Zr and Hf using LMCT as compared to there neutral species. *Adapted from Dunlop, D., Vecera, M., Gyepes, R., Kubat, P., Lang, K., Horacek, M., et al., 2021. Luminescent cationic group 4 metallocene complexes stabilized by pendant N-donor groups. Inorg. Chem. 60 (10), 7315−7328. With Permission.*

Yam et al. (1998) synthesized a series of luminescent hafnium thiolate complexes $(\eta5\text{-}C_5Me_5)_2Hf(SR)_2$ (where R = nBu, C_6H_5, C_6H_4OMe-p, C_6H_4tBu-p) by the reaction of $(\eta5\text{-}C_5Me_5)_2HfCl_2$ with LiSR. It was observed that these complexes exhibited rich luminescence behavior. Gong and Zhou (2007) prepared $OHf(\eta2\text{-}O_2)(\eta2\text{-}O_3)$, as a side-on bonded oxo−superoxo hafnium ozonide complex. This complex has two possibilities on visible light irradiation (532 nm) (i) rearranges photochemically to a more stable $Hf(\eta2\text{-}O_2)_3$ isomer, i.e. a side-on bonded di-superoxo hafnium peroxide complex, (ii) Reacts with dioxygen to form an unprecedented homoleptic tetra-superoxo hafnium complex: $Hf(\eta2\text{-}O_2)_4$. It was found that these oxygen-rich complexes are photoreversible in nature, which means formation of $Hf(\eta2\text{-}O_2)_3$ and $Hf(\eta2\text{-}O_2)_4$ was accompanied by demise of $OHf(\eta2\text{-}O_2)(\eta2\text{-}O_3)$ in prescence of visible light (532 nm) irradiation and vice versa with UV light (266 nm) irradiation.

Chernii et al. (2012) synthesized some phthalocyanine complexes of zirconium (IV) and hafnium (IV) containing dibenzoylmethane groups as out-of-plane ligands As-prepared compounds (ZrN_4O_4 and HfN_4O_4) were isomorphous in nature and their central atoms exhibited square-antiprism coordination geometry, with four nitrogen atoms from the phthalocyanine macrocycle and four oxygen atoms from the two bidentate dibenzoylmethane ligands. There is a high ability of this complex to self-associate in the gas phase. The spectral-luminescent properties of these compounds in different solvents were studied and fluorescence quantum yields of these complexes were determined in toluene and DMSO.

As nanoscale metal organic frameworks (NMOFs) have potential in biomedicine due to their structural/chemical diversities, and high molecular loading capacities. Liu et al. (2016b) reported NMOF composed by hafnium

(Hf^{4+}) and tetrakis (4-carboxyphenyl) porphyrin (TCPP). In as-prepared Hf-TCPP NMOFs, TCPP acts as photosensitizer in photodynamic therapy (PDT), while Hf^{4+} could serve as a radio-sensitizer to enhance radiotherapy (RT). It was observed that NMOFs with polyethylene glycol (PEG) coating exhibited efficient tumor homing upon intravenous injection, and therefore, could be used for in vivo combined RT & PDT, with a remarkable anti-tumor effect. It was interesting to observe that Hf-TCPP NMOFs show efficient clearance from the body of mouse after use; thus, minimizing their possible long-term toxicity. These multifunctional NMOFs can be used as biodegradable carrier-free system, where both; metal ions as well as organic ligands are completely utilized to exert their therapeutic functions.

The Ti-, Zr-, and Hf-phthalocyanines were synthesized by Starukhin et al. (2017), which contain chloride ions or dibenzoylmethanate fragments coordinated to macrocycle in out-of-plane positions. It was observed that an efficient intersystem crossing was there for Hf-phthalocyanine, which leads to very weak fluorescence with lifetimes to <1 ns. It was intresting to note that variation in the nature of central metals from heavy Hf(IV) atom was also changed with lighter atoms: Ti(IV), and Zr(IV) lead to an increasing fluorescence lifetimes and maximum value of 6.6 ns was observed for Mg-phthalocyanine. The values of fluorescence quantum yield was raised from 1% for Hf-phthalocyanine to 56% for Mg-phthalocyanine on such a change. This type of heavy atom effect has impact on photophysical parameters of metallocomplexes containing phthalocyanines as compared to influence of attachment out-of-plane ligands.

Kuhlmann et al. (2018b) synthesized a series of 10 heteroleptic and homoleptic mononuclear Zr(IV) and Hf(IV) complexes with different substituted phenoxy-benzoxazole ligands. It was found that molecular structures were octahedral or tetragonal-antiprismatic coordination motifs at the metal atom and crystal packing patterns was dependent on the substitution of the ligands. It was revealed that all these 10 complexes exhibited a ligand-centered fluorescence with emission maxima in the blue region.

Lamač et al. (2022) reported cationic metallocene complexes, containing with pendant N-donor moieties. These complex exhibited enhanced luminescence in the solid-state, which, may be due to their triplet states with luminescence quantum yields, ΦL, (approximately 0.52), not reported so far for this class of compounds. It was suggested that these complexes can be used as an efficient singlet oxygen photosensitizers. They also evaluated photogeneration of $O_2(^1\Delta_g)$ by Ti, Zr and Hf metallocenes in dichloromethane solution. It was reported that cationic Zr and Hf metallocenes stabilized by N-donor imine and pyridine moieties on excitation by UV A light, exhibited green, yellow or orange luminescence from long-lived ^{3}LMCT excited states (with ΦL $\sim$0.02−0.40 in argon-saturated solutions) and efficient O2(1Δg) production (ΦΔ $\sim$0.29−0.77 in air-saturated solutions).

Chapter 4

Coordination compounds of vanadium, niobium and tantalum

Chetna Ameta, Dharmendra, Yogeshwari Vyas and Purnima Chaubisa
Department of Chemistry, Mohanlal Sukhadia University, Udaipur, Rajasthan, India

4.1 Introduction

Group 5 element, vanadium, niobium, and tantalum form a series of complexes with different ligands. These complexes exhibited different photophysical and photochemical behaviors apart from normal properties. Some of their complexes also show metal-to-ligand-charge transfer (MLCT). These complexes find various applications in photosplitting of water, photodynamic therapy, and photodegradation of organic pollutants. There are good future prospects of these complexes in years to come.

The creation of Jablonski diagrams for metal complexes is almost similar to that of organic molecules (Adamson et al., 1968). According to the predominant atomic orbital contributions, different MOs can be simply classified as follows:

(i) Predominantly ligand centered σ_L orbitals (strongly bonding)
(ii) Predominantly ligand-centered π_L orbitals (bonding)
(iii) Metal-centered π_M orbitals of t_{2g} symmetry (essentially nonbonding)
(iv) Predominantly metal-centered σ_M* orbitals of e_g symmetry (antibonding)
(v) Predominantly ligand-centered π_L* orbitals (antibonding) and
(vi) Predominantly metal-centered σ_M* orbitals (strongly antibonding).

The orbitals of types (i) and (ii) are filled in the ground state electronic configuration of an octahedral complex of d^n metal ion, while n electrons occupied the orbitals of (iii) and (iv) types. Excited electronic state configurations can be obtained from the ground electronic state configuration by promoting an electron from occupied MO to vacant MO in case of organic

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00007-1

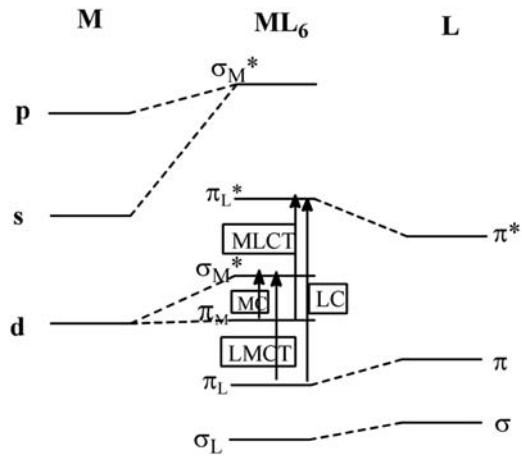

FIGURE. 4.1 Molecular orbital diagram for an octahedral complex of a transition metal.

compounds. These electronic transitions are expected to occur at low energy (Fig. 4.1):

- Metal-centered (MC) transitions from orbitals of type (iii) to orbitals of (iv) type,
- Ligand centered (LC) transitions from orbital of (ii) to (v) type,
- Ligand-to-metal charge-transfer (LMCT) transitions from (ii) to (iv) type, and
- Metal-to-ligand charge-transfer (MLCT) transitions, from (iii) to (v) type.

The relative order of energy of the resultant excited electronic configurations is affected by the type of metal and ligands. These are:

- Low-energy metal-centered transitions are there in case of metals in the first transition series (3d series).
- Low-energy ligand-to-metal charge-transfer transitions are there, when the metal can be easily reduced and at least one ligand is easily oxidized and
- Low-energy metal-to-ligand charge-transfer transitions are there, when reverse conditions are there i.e., when a ligand is easily reduced and metal is easy to oxidized.
- Low-energy ligand-centered transitions can also expected.

As coordination compounds have high symmetry and open-shell ground configurations, and therefore, transition is simpler as compared to organic molecules (partially occupied HOMOs) (Calvert et al., 1966; Balzani et al., 2007).

4.2 Coordination compounds of vanadium

Vanadium (V) was discovered in the form of vanadinite ($Pb_5(VO_4)_3Cl$) in 1801. Vanadium was given the name "panchromium" at that time because its

salts were found in a wide range of colors. This chemical element was discovered in the form of oxide. It was named as "vanadium" after Vanadis, which is a goddess in Norse mythology. Vanadium is a member of first-row transition metal (3d metals). It belongs to group 5 and its atomic number is 23, which has electronic configuration as [Ar] $3d^3 4s^2$. Vanadium is fifth (0.019%) in all transitional metals and 20 second in all elements in the Earth's crust. It is a transition metal with various oxidation states from +II to +V.

Vanadium complexes exist in all oxidation states starting from +I to +V that suggests that vanadium (II) (d^3) may undergo some photochemical redox processes. If photooxidation of vanadium (II) is followed by a second thermal electron transfer, it formed vanadium (IV), and the entire two-electron-transfer process is initiated photochemically. Shah and Maverick (1986) observed the photochemistry of vanadium(II) complexes of 2,2′-bipyridine and 1,10-phenanthroline. The lowest energy excited states in such vanadium systems are most probably either quartet MLCT states or $^2E/^2T_1$. Electrode potentials for these $V(NN)_3^{3+/2+}$ couples were found to be approximately 0.09 and 0.13V, where NN is bpy and phen, respectively. It was revealed that when the lowest energy electronic absorption band of $V(phen)_3^{2+}$ ($\lambda_{max} = 640$ nm) was irradiated in the presence of different electron acceptors, then there is one-electron oxidation leading to the formation of $(phen)_2V(\mu\text{-}OH)_2V(phen)_2^{4+}$. The $V(NN)_3^{2+}$ complexes followed similar photoredox mechanisms. The first step is oxidative quenching of $V(NN)_3^{2+}$ excited state, which is followed by hydrolysis and dimerization during the process of photooxidation process. They reported that reactions using methyl viologen (MV^{2+}) and Eu^{3+} followed the pathway:

$$V(phen)_3^{2+}\ (^4A_2) \xrightarrow[<35\ ps]{hv} V(phen)_3^{2+*}\ (2E \text{ or } MLCT)$$

$$V(phen)_3^{2+*} + A \longrightarrow V(phen)_3^{3+} + A^-$$

$$2V(phen)_3^{3+} + 2H_2O \longrightarrow (phen)_2V^{III}(\mu\text{-}OH)_2V^{III}(phen)_2^{4+} + 2phen + 2H^+$$

The three glycine-peroxo complexes of vanadium-(V), $NH_4[VO(O_2)_2GlyH]\cdot H_2O$, $K[VO(O_2)_2\text{-}GlyH]\cdot H_2O$ and $[V_2O_2(O_2)_3(GlyH)_2(H_2O)_2]$ have been synthesized by Bhattacharjee et al. (1990) from the reaction of V_2O_5 with hydrogen peroxide and glycine (GlyH) at different pH. It was reported that when glycine is in its zwitterionic form, it is coordinated to the V(V) center in a monodentate fashion through its carboxylic oxygen, and the peroxides are there as terminal bidentate ones in first two complexes, but one of the peroxide ligands is present as a μ-peroxo group in third complex. It was revealed that an aqueous solution of second complexexhibited peroxo-V(V) LMCT bands at 328 and in the 200−190 nm region, while third complex has only one broad LMCT band at 310−330 nm.

Sun et al. (2012) synthesized three new oxovanadium(IV) complexes with Hypocrellin B (HB), as a bridging ligand (where phen = 1,10-phenanthroline, tmp = 3,4,7,8-tetramethyl-1,10-phenanthroline and dpq = dipyrido[3,2-f:2′3′-h]quinoxaline) as terminal ligands. It was found that VO^{2+}-HB complexes exhibited higher water solubility, binding affinity toward dsDNA, absorptivity in the phototherapeutic window, and singlet oxygen quantum yield as compared to HB; thus, enhanced DNA photocleavage activity.

Holder et al. (2013) synthesized mixed-metal binuclear ruthenium(II)−vanadium(IV) complexes, and used them as potential photodynamic therapeutic agents for melanoma cell growth inhibition. They reported that complex, $[Ru(pbt)_2(phen_2DTT)](PF_6)_2 \cdot 1.5H_2O$ (where phen$_2$DTT = 1,4-bis(1,10-phenanthrolin-5-ylsulfanyl)butane-2,3-diol and pbt = 2-(2′-pyridyl) benzothiazole), [VO(sal-L-tryp)(H_2O)] (where sal-L-tryp = *N*-salicylidene-L-tryptophanate) afforded $[Ru(pbt)_2(phen_2DTT)VO(sal\text{-}L\text{-}tryp)](PF_6)_2 \cdot 5H_2O$; while [VO(sal-L-tryp)($H_2O$)] was treated with $[Ru(pbt)_2(tpphz)](PF_6)_2 \cdot 3H_2O$ (where tpphz = tetrapyrido[3,2-*a*:2′,3′-*c*:3″,2″-*h*:2‴,3‴-*j*]phenazine) to from $[Ru(pbt)_2(tpphz)VO(sal\text{-}L\text{-}tryp)](PF_6)_2 \cdot 6H_2O$. They carried out in vitro cell toxicity studies (with the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) colorimetric assay) *in* dark and light with sodium diaqua-4,4′,4″,4‴ tetrasulfophthalocyanine cobaltate(II) ($Na_4[Co(tspc)(H_2O)_2]$), $[VO(sal\text{-}L\text{-}tryp)(phen)] \cdot H_2O$. The anti-cancer property of the chloride salts of finally produced complexes was found to be further enhanced, when treated cells were exposed to light, while no such observation was there on non-cancerous skin fibroblast cells. There is a great potential for using such mixed-metal binuclear ruthenium(II)−vanadium(IV) complexes to fight skin cancer.

Apostolopoulou et al. (2015) reported a DSSC using an electrolyte based on square pyramidal oxidovanadium(IV/V) complexes (Fig. 4.2). This oxidovanadium(IV) complex $(Ph_4P)_2[V^{IV}O(hybeb)]$ was combined with its oxidized analogue $(Ph_4P)[V^{V}O(hybeb)]$ {where $hybeb^{4-}$ = diamidodiphenolate ligand [1-(2-hydroxybenzamido)-2-(2-pyridinecarboxamido)benzenato}and applied as a redox couple in the electrolyte of DSSCs. They applied these complexes as a new redox mediator in DSSCs, with the Ru-based sensitizer N719 absorbed on a TiO_2 semiconducting film. They observed maximum energy conversion efficiencies of 2% at simulated solar light (AM 1.5; 1000 W m^{-2}) with an open circuit voltage (V_{oc}) of 660 mV, a short-circuit current (Jsc) of 5.2 mA cm^{-2} with a fill factor of 0.58 were achieved.

Gazi et al. (2015) observed that base metal vanadium photocatalysts can harvest visible light to carry out chemoselective C−C bond cleavage of lignin model compounds. Lignin is a major aromatic constituent of non-food biomass, which is inexpensive, and accessible source of fine chemical feedstocks such as phenols and aryl ethers. They have also reported that a new C−C activation reaction with high conversions under mild conditions. Visible light was used in the presence of earth-abundant vanadium oxo catalysts under

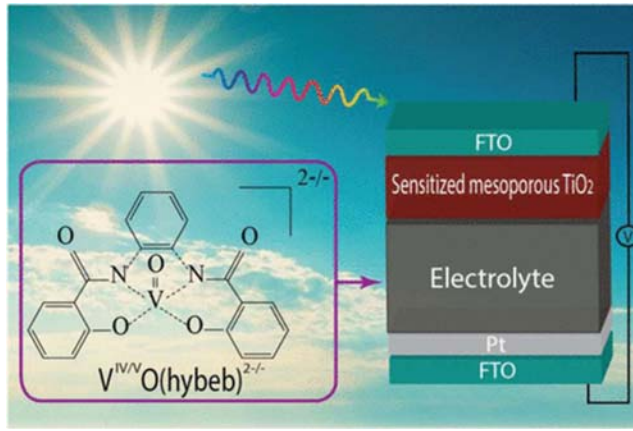

FIGURE. 4.2 Dye-sensitized solar cell involving vanadium complex. *Adapted from Apostolopoulou, A., Vlasiou, M., Tziouris, P.A., Tsiafoulis, C., Tsipis, A.C., Rehder, D., et al., 2015. Oxidovanadium (IV/V) complexes as new redox mediators in dye-sensitized solar cells: a combined experimental and theoretical study. Inorg. Chem. 54 (8), 3979–3988, with permission.*

ambient conditions. It was suggested that this is a unique pathway involving a photogenerated T_1 state during the C–C bond cleavage reaction. It is a sustainable approach to harvest sunlight for an unusual, and selective bond activation, which has potential for application in biomass valorization and organic transformations.

Sanasam et al. (2020) prepared four oxidovanadium (IV) complexes of 1H-imidazo[4,5-f][1,10]phenanthroline analogs with the general formula $[VO(L)_2](acac)_2$. They also evaluated their in vitro photodynamic activity. They reported that 1-(pyren-2-yl)-1H-imidazo[4,5-f][1,10]phenanthroline oxidovanadium(IV) complex exhibited remarkable photocytotoxicity in HaCaT cells. The IC_{50} of this complex was 8.2 μM under visible light (400–700 nm), but it was found to be less toxic in dark (IC_{50} ~70 μM). Its photophysical studies indicated that the lowest triplet excited states of this complex was long-lived and facilitated effective intersystem crossing, which resulted in the efficient generation of $^1O_2$ with good quantum yields (0.49).

Luminescence at room temperature from Earth-abundant metal ions in solution is a quite challenging as no Earth-abundant first-row transition metal complexes displayed emission (more than >1000 nm). Dorn et al. (2020) reported a vanadium(III) complex *mer*-$[V(ddpd)_2][PF_6]_3$, which exhibited phosphorescence around 1100 nm (in valeronitrile glass at 77 K) as well as at room temperature (in acetonitrile) with quantum yield 1.8×10^{-4}% (where ddpd = *N*,*N*′-dimethyl-*N*,*N*′-dipyridine-2-ylpyridine-2,6-diamine) (Fig. 4.3). This *mer*-$[V(ddpd)_2][PF_6]_3$ also revealed strong blue fluorescence with 2% quantum yield in acetonitrile at room temperature.

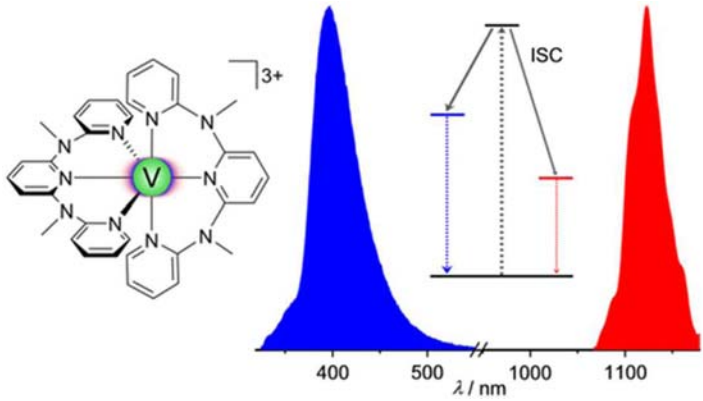

FIGURE. 4.3 Phosphorescence in *mer*-$[V(ddpd)_2][PF_6]_3$. *Adapted from Dorn, M., Kalmbach, J., Boden, P., Päpcke, A., Gómez, S., Förster, C., et al., 2020. A vanadium (III) complex with blue and NIR-II spin-flip luminescence in solution. J. Am. Chem. Soc. 142 (17), 7947−7955, with permission.*

Fomenko et al. (2021) prepared and investigated photochemistry of the binuclear heterometallic complex $[Ru(NO)(NO_2)_2(\mu\text{-}NO_2)(\mu{-}CH_3COO)(\mu\text{-}O)VO(dbbpy)]\cdot CH_3CN$ (where bdbbpy = 4,4′-di-tert-butyl-2,2′-bipyridyl). It was reported that acetonitrile solution of the complex undergoes an NO photo-release reaction on irradiation at 445 nm. It was observed that light excitation induces the charge transfer from NO_2 and dbbpy ligands to the antibonding orbitals of ON−Ru−O−V chain, and as a result, NO release is there. It was found that quantum yield of the Ru−NO photo-cleavage is 0.57 ± 0.05%. This complex represents a bifunctional platform, which can release nitric oxide in solution and reversibly switch the NO ligand coordination in the solid state. It was also found that the presence of vanadium strongly influences the photochemical properties of ruthenium nitrosyl in both; solid phase and solution.

Four new ternary oxovanadium(IV) complexes, $[VO(L)(B^{1\text{-}4})](acac)$ (where L = (E)-2-(2-hydroxybenzylideneamino)-5-guanidinopentanoic acid (Argininesalisylidene), 1H-imidazo-[4,5-f][1,10]-phenanthroline, 2-phenyl-1H-imidazo [4,5-f][1,10] phenanthroline, 2-(naphthalen-1-yl)-1H-imidazo [4,5-f][1,10] phenanthroline and (1-(pyren-2-yl)-1H-imidazo[4,5-f][1,10] phenanthroline) were synthesized by Sanasam et al. (2021). They also studied photocytotoxicity in A549 cell in dark and visible light (400−700 nm, 10 J cm^{-2}). They investigated that photochemistry of these four complexes is related to the generation of singlet oxygen ($^1O_2$). The degree of photocytotoxicity of the complexes was related to their ability in photo-activated $^1O_2$ generation. It was observed that four complex exhibited remarkable photocytotoxicity in A549 cells with its photo index (PI) ∼ 16 in visible light (400−700 nm, 10 J cm^{-2}) (IC_{50}, 3.81 μM), while complexes were almost less-toxic in dark (IC_{50}, 59.7 μM). A remarkable photocytotoxic efficacy of these

oxovanadium(IV) complexes can be promising photochemotherapeutic agents in place of porphyrin-based PDT agents.

Heller et al. (2021) observed photochemistry of hydrated vanadium ions (positively charged), $V^{+}(H_2O)_n$, where n = 1 to 41. It was found that there were electronic excitations related to the V^{+} core in clusters with up to 12 water molecules. There were strong 3d−4p transitions, which is redshifted, when vanadium is solvated more and it reaches a saturated initial solvation shell with 4 coordinated water molecules, which produced; $[HVOH(H_2O)_{n-1}]^{+}$. The structure and change of oxidation state of vanadium was from +I to +III, which started, where n is around 9. They observed that internal conversion (IC) and intersystem crossover (ISC) were shown as photochemical relaxation processes in this $V^{+}(H_2O)$ system (Fig. 4.4), leading to decomposition in low-lying triplet or quintet states. It was interesting to note that photons in different ranges behaved in different manner such as low photon energies (yellow, <1.5 eV) prevented fragmentation, while increased excitation energies (green, ~2 eV) allowed water loss. The more energy (blue, ~2.4 eV) allowed water splitting in the triplet manifold and it is also possible to eliminate hydrogen molecules with transition state (TS), hydrogen radical loss and water removal are become increasingly significant with increasing photon energy (purple, ~3.8 eV).

Zhang et al. (2021) investigated photochemical activation of C−H bonds by vanadium(V)−dioxo and vanadium(V)−oxo−peroxo diimine complexes. Organic substrates were selected with C−H bond having dissociation free energy between 70 and 97 kcal mol^{-1}. Compounds having weaker C−H bonds are earily oxidized and that too, in minutes, which otherwise takes days for

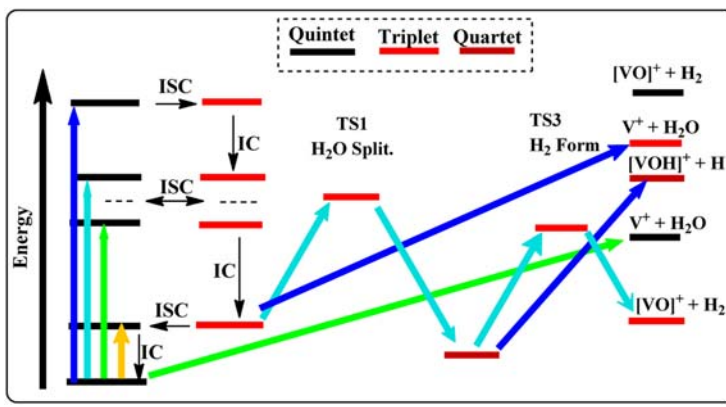

FIGURE. 4.4 Some photochemical relaxation processes in the $V^{+}(H_2O)$ system. *Adapted from Heller, J., Pascher, T.F., Muß, D., van der Linde, C., Beyer, M.K., Ončák, M., 2021. Photochemistry and UV/vis spectroscopy of hydrated vanadium cations, V+(H2O)n, n = 1−41, a model system for photochemical hydrogen evolution. Phys. Chem. Chem. Phys. 23 (39), 22251−22262, with permission.*

thermal oxidation by these complexes. It was observed that dioxygen was necessary for substrate consumption, suggesting that these electronically excited V complexes are radical reaction initiators through H-atom abstraction from the organic substrate.

Jose et al. (2022) synthesized vanadium complex anchored reduced graphene oxide (rGO-VO) by coordination interaction with phenyl azo salicylaldehyde (PAS) coupled trimethoxy silyl propanamine (TMSPA). They also studied physicochemical properties of rGO-VO. The photocatalytic studies of this anchored rGO-VO and $VO(acac)_2$ was also investigated for its use in methylene blue degradation, which indicated that methylene blue was degraded fast (about 64.2%) in 100 min under visible light irradiation in presence of anchored rGO-VO as compared to $VO(acac)_2$.

Psoriasis is a chronic inflammatory skin disease that can significantly impact the quality of human life. Various drug treatments are available; however, due to their long-term severe side effects, the usage of these drugs is limited. Photodynamic therapy (PDT) has been clinically approved for skin diseases due to its non-invasive nature. Lin et al. (2022) presented NNO-tridentate vanadium(IV) complexes, which has been used in PDT for anti-inflammatory effects in an imiquimod-induced psoriasis-like skin disease mouse model. They synthesized vanadium(IV) complexes using the NNO-tridentate ligand with a benzo[*i*]dipyrido[3,2-*a*;2′,3′-*c*]phenazine (dppn) moiety. It was found that photocytotoxicity of these vanadium(IV) complexes was low in dark, but fourth complex exhibited remarkable photocytotoxicity under blue light irradiation. It was suggested that [VO(*t*-butylL)(dppn)] could be a promising candidate for the treatment of psoriasis both; in vitro and in vivo.

4.3 Coordination compounds of niobium

Niobium is a shiny and silvery metal. It has an atomic number of 41 and belongs to group 5 with electron configuration $[Kr]4d^45s^1$. The oxidation state of niobium varies from +II to +IV. It is relatively soft and flexible, when very pure but impurities make it harder. Niobium is also used in alloys including stainless steel, and used in jet engines, rockets, oil rigs, and oil gas pipelines, prosthetics and implant devices, such as pacemakers.

Foust et al. (1982) reported the photolysis of $Nb(\eta^5\text{-}C_5H_5)_2H_3$ in C_6D_6 with H/D interchange with benzene. The photolysis of toluene solution of $Nb(\eta^5\text{-}C_5H_5)_2H_3$ in the presence of ligands formed $Nb(\eta^5\text{-}C_5H_5)_2(H)L$, where ligand is CO, and PEt. It was also revealed that the $Nb(\eta^5\text{-}C_5H_5)_2(H)CO$ complexes react photochemically with H, or PEt ligands and as a result, $Nb(\eta^5\text{-}C_5H_5)_2H_3$ and $Nb(\eta^5\text{-}C_5H_5)_2(H)PEt_3$ are produced, respectively. These reactions supported the participation of $Nb(\eta^5\text{-}C_5H_5)_2H$ as an intermediate from $Nb(\eta^5\text{-}C_5H_5)_2H_3$ and $Nb(\eta^5\text{-}C_5H_5)_2(H)CO$.

$$NbCp_2H_3 \xrightarrow{hv,\ Ar} NbCp_2H + H_2$$

$$NbCp_2(H)CO \xrightarrow{hv,\ Ar} NbCp_2H + CO$$

Clark (1984) investigated the photochemistry of some niobium complexes, $NbCp_2(X)(CO)$ (where $Cp = \eta^5\text{-}C_5H_5$, and $X = H$, Cl, CH_3, and C_6H_5) on irradiation in the presence of neutral ligands. It was observed that irradiation of $NbCp_2H(C_2H_4)$ in the presence of H_2, C_2H_4, PMe_2Ph, $P(OMe)_3$, and PPh_3 resulted in addition of a hydrogen ligand into the coordinated ethylene, but then substitution of ethylene was the main path in the existence of CO. The photochemistry of $NbCp_2H_3$ was studied and it was reported that chemistry of this trihydride is further complex in nature and it has numerous reactions.

$$NbCp_2H_3 + L \xrightarrow{h\nu} NbCp_2H(L) + H_2$$

A series of bimetallic compounds were obtained, when the trihydride of niobium was photolyzed using metal carbonyls. All of which cover the $NbCp_2(CO)$ part;

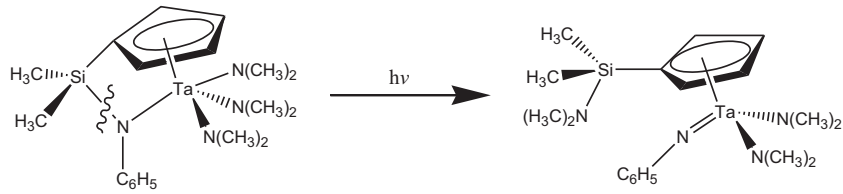
$$NbCp_2H_3 + NbCp(CO)_4 \xrightarrow{h\nu} NbCp_2CO(u\text{-}H)NbCp(CO)_3$$

$$NbCp_2H_3 + MnCp(CO)_3 \xrightarrow{h\nu} NbCp_2CO(u\text{-}H)MnCp(CO)_2$$

$$NbCp_2H_3 + M(CO)_3 \xrightarrow{h\nu} NbCp_2CO(u\text{-}H)M(CO)_5 \quad (M=Cr, Mo, W)$$

$$NbCp_2H_3 + Mn_2(CO)_{10} \xrightarrow{h\nu} [(NbCp_2CO)_2(u\text{-}H)]^+Mn(CO)_5^-$$

Baynham et al. (1985) carried out photolysis of $Nb(\eta^5\text{-}C_5H_5)_2H_3$ in nitrogen and argon atmospheres, which produces 16 electron complex $Nb(\eta^5\text{-}C_5H_5)_2H$. It was earlier assumed to be an intermediate in the catalytic initiation of aryl C—H bonds. It was reported that complexes were produced through photolysis of $Nb(\eta^5\text{-}C_5H_5)_2(H)CO$, self-possessed by minor quantities of the 17 electron $Nb(\eta^5\text{-}C_5H_5)_2CO$. It was also revealed that $Nb(\eta^5\text{-}C_5H_5)_2H_3$ was transformed to $Nb(\eta^5\text{-}C_5H_5)_2(H)CO$ in the CO medium while an advance reaction of $Nb(\eta^5\text{-}C_5H_5)_2(H)CO$ produces $Nb(\eta^5\text{-}C_5H_5)_2CO$ and some dicarbonyl products.



Cao et al. (2015) introduced niobium complex into atom transfer radical polymerization (ATRP) system and used as recyclable photocatalyst. Here, niobium complex acted as photocatalyst, which could be activated by the photoredox reaction in presence of visible light using ethyl 2-

bromoisobutyrate (EBiB) as initiator. It was reported that well-defined polymers with controlled molecular weight and narrow polydispersity index (PDI) (Mw/Mn = 1.16−1.30) were obtained on controlling feed ratio of photocatalyst to EBiB. It was also observed that the polymerization was highly responsive to light exposure and initiation and therefore, polymerization can be controlled on or off at ease. Apart from it, the photocatalyst can be recycled and reused again to initiate the polymerization for number of times without any significant loss of efficiency.

Rogachev et al. (2015) carried out some substitution reactions of binuclear niobium cluster anion $[Nb_2S_4(NCS)_8]^{4-}$ with different pyridine-based diimine ligands. The monosubstituted complexes $[Nb_2S_4(NCS)_6L]^{2-}$ were obtained on using 2,2′-bipyridine (bipy) and its derivatives but mono- and disubstituted complexes, $[Nb_2S_4(NCS)_6L]^{2-}$ and $[Nb_2S_4(NCS)_4L_2]$ have been obtained using 1,10-phenanthroline and 2-(2-pyridyl)benzimidazole (Hpbz), respectively. They diffused TiO_2 nanoparticles with $(Et_4N)_2[Nb_2S_4(NCS)_6(bipy)]$, which exhibited moderate photocatalytic activity in generation of hydrogen from water in the presence of Na_2S/Na_2SO_3 as a sacrificial electron donor. It was also reported that complexes with bipyridine ligands can function as broad-band optical limiters.

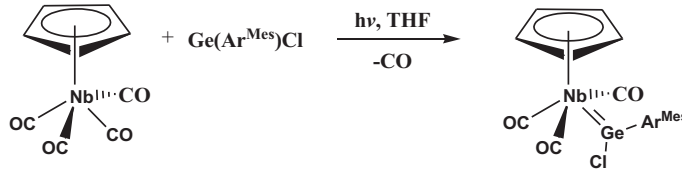
Camp et al. (2016) reported the synthesis and photo-reactivity of d^0 niobium imidoazido complexes supported by β-diketiminate ligands. Nitrides were formed through a photo-assisted intramolecular rearrangement, and it provides a new approach for formation of metal nitrides that does not require low-valent metal centers and it was claimed that it is a rare example, where the metal-imido moiety in complexes belonging to group 5 participates in reactivity.

Filippou el al. (2017) reported that photodecarbonylation of $[(\eta^5\text{-}C_5H_5)Nb(CO)_4]$ in the presence of $Ge(Ar^{Mes})Cl$ afforded a red-orange chlorogermylidene complex $[\eta^5\text{-}C_5H_5(CO)_3Nb = Ge(Ar^{Mes})Cl])$, (where Ar^{Mes} = 2,6-mesitylphenyl). They prepared $[(\eta^5\text{-}C_5H_5)(CO)_4]$ by a modified method and irradiated it in tetrahydrofuran with a high-power blue light LED yielding $Ge(Ar^{Mes})Cl$. It was observed that a relatively selective decarbonylation was there to chlorogermylidene $[\eta^5\text{-}C_5H_5(CO)_3Nb = Ge(Ar^{Mes})Cl]$ complex, in the form of red-orange crystals.

Shmakova et al. (2018) added 2-aminopyridine (2-NH_2-py), 2,2′-bipyridine (Bpy), and 1,10-phenanthroline (phen) in aqueous solutions of (NH_4)

$[NbO(C_2O_4)_2(H_2O)_2]\cdot 3H_2O$ (Nb-Ox) to produce tris-oxalato complexes such as $(BpyH_2)(BpyH)[NbO(C_2O_4)_3]\cdot 2H_2O$, $(2\text{-}NH_2\text{-}pyH)_3$ $[NbO(C_2O_4)_3]\cdot 2H_2O$ and $(phenH)_3[NbO(C_2O_4)_3]\cdot 3H_2O$, respectively. It was reported that complex $(BpyH_2)(BpyH)[NbO(C_2O_4)_3]\cdot 2H_2O$ showed strong blue photocoloration in daylight irradiation. The mechanism of this reaction is light absorption through $BpyH_2^{+\bullet}$ followed by energy transmission to $[NbO\ (C_2O_4)_3]^{3-}$, and electron transmission from the excited anion posterior to the cation fabricating blue cation radical $BpyH_2^{+}$. Here, oxalate ligands generated very reducing anion radical $CO_2^{-\bullet}$, which spreads such blue paramagnetic centers. Therefore, there is a great potential in these niobium oxalates in photochemical procedures such as photocatalysis.

Motorina et al. (2019) studied reactions of pyridine with (5,10,15,20-(tetra-4-tert-butylphenyl)porphinato)trichloroniobium(V) $(Nb(Cl)_3TtBuPP)$ and H+-bonded $Nb(Cl)_3TtBuPP$ $(Nb(Cl)_3TtBuPP\cdots H^+\cdots Cl^-)$ in toluene. It was reported demonstrated that $Nb(Cl)_3TtBuPP$ and $Nb(Cl)_3TtBuPP\cdots H^+\cdots Cl^-$ can be used as optical and fluorescent chemosensors of volatile organic compounds (VOCs) and nitrogenous bases-building blocks of food components, pharmaceuticals, and environmental pollutants. It was found that stability constant of the complex with pyridine $K = (1.99 \pm 0.3) \times 104\ L^2\ mol^{-2}$ and $(2.8 \pm 0.5) \times 10^2\ L\ mol^{-1}$, relative optical response $A = 0.91$ and 0.35, detection limit of pyridine 1.74×10^{-3} and $4.05 \times 10^{-4}\ mol^{-1}\ L$, respectively. These are applicable for use in the design of dye-sensitized solar cells (DSSCs).



Two new dodeca-niobate materials were synthesized by Zhang et al. (2020) via hydrothermal method and these are $K_3[Nb_2O_2][H_7SiNb_{12}O_{40}]\cdot 16H_2O$ $[Cu(en)_2]_9[(VNb_{12}V_{1.69}Nb_{0.31}O_{42}en_{0.31})_2]\cdot 20.69H_2O$ (where en = ethylenediamine). It was revealed that first compound had a bridging layer structure model and K plays a great role in its three-dimensional structure. On the other hand, second was capped Keggin POM with organic ligand chelating the capping atom. Their activity for photocatalytic hydrogen evolution and epoxidation of styrene has been evaluated. It was found that first was also a good photocatalyst to degrade rhodamine B.

4.4 Coordination compounds of tantalum

Tantalum belongs to group 5 and its atomic number is 73. Tantalum has filled 4f orbitals and 6s orbitals but 5d orbitals has only 3 electrons having electronic configuration as $4f^{14}5d^36s^2$. Its normal oxidation state is +V, but at extreme conditions of pressure and temperature, it can have a +II oxidation state. It is chemically stable, and is only attacked by strong alkalis and acids. It is corrosion-resistant, since it adsorbed O_2 and forms a passivating layer of Ta_2O_5. Tantalum is a suitable material for capacitors. Tantalum has several uses in electronics, medical fields, superalloys, capacitors, ballistics, chemical

processing. Tantalum is also used in making surgical sutures and prosthetic devices.

Herrmann and Baratta (1996) reported that niobium(V) amides [(η^5-C_5H_4)$-Si(CH_3)_2$-NR]Nb[$N(CH_3)_2]_3$ (where R = C_6H_5) having chelate like C, N-Ligands with 45% inaccessible product from the N-functionalized cyclopentadiene $C_5H_5-Si(CH_3)_2$-NHR and homoleptic amides M[$N(CH_3)_2]_5$ with binary amine subtraction. It was revealed that niobium derivatives exhibited an unparalleled photo-incited readjustment at room temperature, which afforded imido complexes [(η^5-C_5H_4)$-Si(CH_3)_2-N(CH_3)_2$]Nb(=NR)[$N(CH_3)_2]_2$ as a product 60% yield due to Si−N bond cleavage. Such Si−N bond cleavage in niobium complex, tris(dimethyl amido) [η^1:η^5-{(N-phenylamido)dimethyl-silyl} cyclopentadienyl]niobium(V) is there form bis (dimethylamido)(N-phenylimido)[η^5-{(dimethyl-amido)(dimethyl-silyl)} cyclopentadienyl] niobium(V) in presence of visible light in solution as well as in the solid-state.

A series of η^5-pentamethylcyclopentadienyl tantalum(V) complexes have been prepared by Tonzetich et al. (2003). Their electronic and emission spectra were also examined. Compounds of the form Cp*TaX_4 (where X = Cl, Br, or OC_6F_5) and Cp*$TaCl_2X_2$ (where X = OC_6Cl_5, or 2,6-$OC_6H_3Cl_2$) have been found to luminesce at 77 K in frozen glasses. The shifts in luminescence maxima with ligand variation lead to the conclusion that the emissive state is a ligand-to-metal charge transfer, in which the highest occupied orbital is based on the donor atom of one of the monodentate ligands and the lowest unoccupied orbital is Ta-based.

Tonks and Bercaw (2010) synthesized two complexes of tantalum (dme) $TaCl_3(NNPh_2)$ and (dme)$NbCl_3(NNPh_2)$ (where dme = 1,2-dimethoxyethane) from MCl_5 and diphenylhydrazine via a Lewis-acid assisted dehydrohalogenation reaction. It was reported that first complex was monomeric in nature and it contains a κ^1-bound hydrazido(2-) moiety, but its corresponding imido derivatives is dark blue because of LMCT, which has been lowered in energy as a result of an $N_\alpha-N_\beta$ antibonding interaction that raises the level of highest occupied molecular orbital (HOMO). It was also observed that reaction of first complex with different neutral, mono- and dianionic ligands generated the corresponding ligated complexes retaining the κ^1-bound [Ta−$NNPh_2$] moiety.

Chauke et al. (2011) synthesized the tantalum (III) hydroxide complex and reported its photochemical application in the oxidation of cyclohexene to various products (cyclohexanol, cyclohexanediol, and cyclohexane oxide)

using it with the gold nanoparticles (Au NPs). The selectivity of products is in the order:

For tantalum (III) hydroxide complexes:

1,2-Cyclohexanediol (24.5%) > Cyclohexene oxide (12.3%) > 2-Cyclohexene-1-ol (11.6%) > 2-Cyclohexene-1-one (9.7%)

For tantalum (III) hydroxide complexes Au NPs:

1,2-Cyclohexanediol (17.6%) > Cyclohexene oxide (12.9%) > 2-Cyclohexene-1-ol (8.6%) > 2-Cyclohexene-1-one (7.2%)

Some brightly colored terminal hydrazido(2−) (dme)$MCl_3(NNR_2)$ complexes (where dme = 1,2-dimethoxyethane; M = Nb, Ta; and R = alkyl, aryl) have been synthesized by Tonks et al. (2012) (Fig. 4.5). It was observed that perturbation of the electronic environment of the β (NR_2) nitrogen affected the energy of the lowest-energy charge-transfer (CT) transition in these complexes. It was revealed that increasing the energy of the Nβ lone pair resulted in a decrease in the ligand-to-metal charge transfer (LMCT) energy, except for electron-rich niobium dialkylhydrazides. It was revealed that photophysical properties of these complexes had a potential redox noninnocence of hydrazido ligands, which could lead to ligand- and/or metal-based redox chemistry.

A simple and inexpensive method was reported by Ramos et al. (2015) for synthesis of a new series of β-diketonate-tantalum complexes. They used $[TaF_7]^{2-}$ solution (as the precursor of tantalum), thenoyltrifluoroacetone (TTA), hexafluoroacetylacetone (HFA), and benzoyltrifluoroacetylacetone (BFA) in basic medium. The pH was maintained using urea in the reaction medium. It was revealed that these complexes (in the solid state and in solution) upon irradiation with UV light at room temperature exhibited blue emission, and it may be due to heavy atom effect. It was suggested that these β-diketonate complexes have a great potential for application as optical ethanol, humidity sensors and materials for the development of luminescent devices.

Groups 5 and 6 terminal hydrazido (2−) complexes: Nβ substituent effects on ligand-to-metal charge-transfer energies and oxidation states. J. Am. Chem. Soc. 134 (17), 7301−7304, with permission.*

Zhao et al. (2018) prepared tantalum phosphate, trideca-sodium distrontium ditantalum nona-phosphate, $Na_{13}Sr_2Ta_2(PO_4)_9$, using the high-temperature flux method. It was revealed that it is an insulator with band gap of 4.78 eV, which makes it suitable as a luminescent host matrix. A series of solid solutions, i.e., $Na_{13}Sr_2Ta_2(PO_4)_9$:xDy^{3+} (where x = 0.01, 0.02, 0.04, 0.06, 0.08, 0.1, 0.12 and 0.14), were prepared and their photoluminescence properties were studied. It was reported that these emit two typical emissions of the Dy^{3+} ion, i.e., the $^4F_{9/2} \rightarrow {}^6H_{15/2}$ transition (476 nm) and the $^4F_{9/2} \rightarrow {}^6H_{13/2}$ transition (570 nm) under 350 nm light excitation.

Hao et al. (2022) used tantulum ureate (pre-catalyst), for photocatalytic hydroaminoalkylation of unactivated alkene with unprotected amine at room temperature. A unique reactivity were observed, when $Ta(CH_2SiMe_3)_3Cl_2$ and ureate ligand were combined with saturated cyclic backbone. They evaluated Ta photocatalytic hydroaminoalkylation (β-alkylation of amine) with an idea of finding the scope of substrate. It was suggested that both; similarities as well as differences were observed in reaction mechanism with Ta catalyzed hydroaminoalkyaltion under thermo-conditions.

Hernández et al. (2022) developed a single-step synthesis of $\{Ta_6Br^i_{12}\}$ @GO (GO = graphene oxide) nanohybrids by immobilizing $[\{Ta_6Br^i_{12}\}Br^a_2(H_2O)^a_4]\cdot 4H_2O$ (i = inner and a = apical positions of the Ta_6 octahedron) on GO nanosheets. They took advantage of an easy ligand exchange of the apical cluster ligands with the oxygen functionalities of GO. It was observed that hybrid formation enhanced the yield of H_2 from photocatalytic splitting of water as compared to their precursors and that two without using precious metals. This increase was attributed to the optimal cluster loading onto the GO support and its crucial role in the electron transfer from Ta_6 clusters into GO sheets; thereby, suppressing the charge recombination. Thus, octahedral tantalum clusters have a potential to develop new and environmentally friendly photocatalysts for generation of H_2 from water.

Chapter 5

Coordination compounds of chromium, molybdenum and tungtsen

Saroj Lohar, Dushyant Kumar Prajapati, Jeevan Kunwar Chouhan, Ankita Vijay and Shipra Bhardwaj
Department of Chemistry, Government Meera Girls College, Udaipur, Rajasthan, India

5.1 Introduction

Coordination compounds or complexes are substances, in which a central metal ion is surrounded by nonmetal atoms or group of atoms, known as ligands. These are joined by coordinate bonds. Coordination compounds were known from the beginning of modern chemistry. The complex ion chain theory was proposed, where the ammonia molecules compensate the charge of the ion by forming chains of $[(NH_3)_x]^{x+}$ ions. Here, x is the coordination number of the metal ion. This ammonia chain was compared to hydrocarbon chain of $(CH_2)_x$. Some commonly known coordination compounds are vitamin B_{12}, hemoglobin, chlorophyll, etc.

Werner's theory is the most accepted theory to explain the bonding in coordination compounds. Alfred Werner proposed this theory in 1893. According to this theory, "if the ions were to form a chain, this would occur outside the coordination sphere" while the ions that bound directly to the metal would do so within the coordination sphere. Since then, a number of coordination complexes have been synthesized, analyzed and applied in various fields. The synthesis of $Cr(CO)_6$ involved treatment of Cr(III) salts with carbon monoxide at high pressure using phenyl magnesium bromides as reductant (Andre and Antoine, 1927; Owen et al., 1950). Chromium(II) acetylacetonate, $Cr(acac)_2$ is air-sensitive, yellow solid and the Cr center is square planar (Cotton et al., 1977) Chromium (III) acetylacetonate was also prepared by the reaction of chromium(III) oxide with acetylacetone. This is a purplish coordination compound and it is used in NMR spectroscopy as a relaxation agent (Fernelius et al., 2007). Ligand field analysis of the double excited states in Cr(III) tris chelated complexes was also carried out (Ceulemans et al., 1987).

Excited state behavior as a probe of ground state ion pair interaction in chromium (III) polypyridyl complexes was presented by Hoffman and Serphone (1987). Structure, reactivity, photochemical and photophysical properties of Cr(III) complexes were also studied extensively in last 2 decades of last century (Ditze and Wesgestion, 1985; Endicott et al., 1986, 1987). The mechanisms of photochemical reactions involving transition metal complexes were studied extensively (Oskam et al., 1987).

The luminescence in transition metal complexes at room temperature in solution on excitation by visible light was paid more attention. Such species have low energy excited states and may be used in preparation of some chemicals because they allow the utilization of optical energy. Bis-donor ligand-substituted tungsten arylcarbyne complexes $[(W{=}CAryl)X(CO)_2L_2]$ (where X = halide, L = donor ligand) has been established as a new class of luminescent organometallic species. The photoemission from tungsten alkylidyne complexes in fluid solution was also studied (Bocarsly et al., 1985). Several tungsten phenylcarbyne complexes of the type $[(WCPh)X(CO)_2L_2]$ have been found to show luminescent behavior at room temperature in fluid phase on excitation with visible radiations (Bocarsly et al., 1987). The synthesis and characterization of some Cr(0), Mo(0) and W(0) carbonyl complexes containing chelating P, N and N, N ligands (2-(2′-pyridyl)-4,6-diphenylphosphinine and 2-(2′-pyridyl)-4,6-diphenylpyridine) was carried out by Krom et al. (2015). Significant changes in these properties of complex on replacing nitrogen atoms by phosphorous atoms are due to electronic differences between the heteroatoms. An attempt was made by Van Atta et al. (2000) to synthesize some $ML(CO)_4$ (where M = Cr, Mo, W; and L = en, bipy, dppm, dppe) complexes in presence of microwaves, resulting in the reduction of reaction times and an increase in yields over conventional syntheses. They also observed reduction in reaction time of about 5−500 folds.

Coordination compounds find a wide range of applications in chemistry, biology as well as medical sciences. These are found as a component in protein, enzymes, vitamin B_{12}, hemoglobin, chlorophyll, dyes, pigments, and as catalysts in preparing organic substances. They can do it due to presence of inner and outer coordination sphere and therefore, two types of reactions are possible simultaneously. Chelation therapy involves chelating agents to trap toxic metal agents, such as arsenic, mercury, and lead, by converting them to a chemically inert form that can be excreted without further interaction with the body.

5.2 Coordination compounds of chromium

Nicolas-Louis Vauquelin, a French chemist, discovered chromium in 1797. This metal was separated, and given the name chromium, because of its pigmented compounds. Small levels of chromium are responsible for different colors in some gems like ruby, emerald, serpentine, etc. This element has the

atomic number 24 and its symbol its Cr. It belongs to group 6. It is tough and brittle. The trivalent and hexavalent species of Cr are stable forms; however, there are some other valence states, which are unstable and transient in biological systems.

Structure, reactivity, photochemical and photophysical properties of Cr(III) complexes were also studied extensively in last 2 decades of last century (Kirk, 1981; Kane-Maguire et al., 1985; Ditze and Wasgestion 1985; Endicott et al., 1986, 1987). Photochemical oxidative substitution of $Cr(CO)_6$ with o-quinones (o-chloranil, 3,5-di-tert-butyl-l,2-benzoquinone) was investigated by two methods stationary as well as flash photolysis in aromatic hydrocarbon solvents (Vlcek, 1986). It was found that photogenerated $Cr(CO)_5$ species was coordinatively unsaturated and it undergoes a rapid oxidative addition of the o-quinone molecule. There was a strong labilization of Cr−CO bonds and CO-free Cr(III) complex [Cr(o-semiquinone)$_3$] was formed.

Indelli and Scandola (1993) synthesized cyano-bridged trinuclear complex [Ru(CN),[Cr(cyclam)(CN)*]$_2$. It was observed that its absorption spectrum was dominated by an intense Ru(I1)−Cr(II1) charge transfer (intervalence transfer) band. Efficient (q = 1) population was there of the Cr(II1)-centered doublet state by excitation into this band giving rise to a characteristic phosphorescent emission. It was reported that efficiency of this unusual process is dependent on the peculiar energetics of the system (activationless crossing between [-Ru(III)−Cr(II)] and [-Ru(11)-*Cr(III)], strongly "inverted" situation between [-Ru(III)−Cr(II)] and [-Ru(11)-Cr(III)]). The electronic states of this dyad system were interconverted ion this sequence ground state-charge-transfer state-locally excited state-ground state is just reverse of normally observed sequence in photoinduced electron transfer.

Delio and Ford (2000) investigated photoreactions of coordinated nitrite ion and reversible nitric oxide labilization from a chromium(III) complex [trans-Cr(cyclam)$(ONO)_2]^+$. It was suggested that such complexes can be used as photochemical source. They observed that there is potential of using such nitrite ion complexes as the photochemical source delivery nitric oxide to biological targets. They also reported photoreactions of the chromium(III) complex, trans-Cr(cyclam)$(ONO)_2^+$ (where cyclam = 1,4,8,11 tetraazacyclotetradecane) to give nitric oxide and Cr(IV) complex, which then changes Cr(V) complexes in the presence of molecular oxygen.

Shaw and Langford (2000) observed the wavelength dependence of photoinduced electron transfer and photosubstitution of $Cr(CNPh)_6$, which has low-lying MLCT states. It was observed that photosubstitution quantum yields increases with increasing excitation energy while photoinduced electron transfer quantum yields decrease with increasing excitation energy. At the lowest excitation energy used (532 nm, or 18 800 cm^{-1}) it was indicated that quantum yields for both these process; electron transfer and photosubstitution

reached same maximum value (0.29). It was also revealed picosecond time-resolved absorption spectra at 355 and 532 nm show two features:

- A bleach signal, which was centered at 400 nm, and an excited state absorption (ESA) in the 600 nm region.
- The ESA signal was found to be much weaker for 532 nm excitation than for 355 nm excitations.

The bleach and ESA decay exponentially with the same lifetime of 23 μs following a 355 nm flash. The $Cr(CNPh)_6$ exhibited two photochemical mechanisms: (i) A simple charge neutral dissociation and at high excitation energy, and (ii) Phenylisocyanide radical anion dissociates in a radical pair at low energy. This pair was considered responsible for the electron transfer reactivity and substitution, as well as complicated nanosecond kinetics. The primary processes for both these reactions take less than 20 ps.

Some new heteroleptic tris(polypyridyl)chromium(III) complexes, $[Cr(phen)_2L]^{3+}$ (L = substituted phenanthrolines or bipyridines), have been prepared by Isaacs et al. (2006). It was reported that both; ground state potentials and lifetime decays were found sensitive to structure of ligand and the nature of the solvent; of course, ligands 5-amino-1,10-phenanthroline (aphen) and 2,2′-bipyrimidine (bpm) are exceptions. It was also observed that addition of electron-donating groups in the ligand shifted the redox potentials to more negative side as compared to parent compound, $[Cr(phen)_3]^{3+}$. The longest lifetime ($\tau = 273$ μs) was observed in case of $[Cr(phen)_2(dip)]^{3+}$, (where dip = 4,7-diphenylphenanthroline) in air-free aqueous solutions.

Ford (2008) reported that electrostatic assemblies are formed between $Cr(L)(ONO)^{2+}$ cations and anionic surface of water-soluble core/shell quantum dots (CdSe/ZnS) and via an ion-pairing mechanism. It was observed that photoexcition of such modified QDs enhanced NO generation and these nanomaterials may have promising applications such as photochemical drugs.

Kushch et al. (2009) derived photochromic paramagnet from polyoxometalate $[Cr(OH)_6Mo_6O_{18}]^{3-}$ and ruthenium mononitrosyl complex $[RuNO(en)_2Cl]^{2+}$. As−prepared bifunctional material $[RuNO(en)_2Cl]_3[Cr(OH)_6Mo_6O_{18}]_2 \cdot 17H_2O$ (where en = ethylenediamine), was observed to have photochromic as well as paramagnetic molecular blocks.

Pokhrel and Nagaraja (2009) investigated photogalvanic behavior of $[Cr_2O_2S_2(1\text{-Pipdtc})_2(H_2O)_2]$ in a Honda cell using pure DMF and its mixture with water. They could obtain maximum potential and current as 200 mV and 18 μA, respectively in DMF. It was also found that this system was reversible, when the irradiated solution was aerated immediately, but when the solution was kept in dark for 12 h and then aerated system was found to be irreversible in nature.

Dethlefsen et al. (2009) prepared nitrosyl complex $[Cr(dmso)_5(NO)](PF_6)_2$ (where dmso = dimethyl sulfoxide) by the solvolysis of $[Cr(NCCH_3)_5(NO)](PF_6)_2$ in neat DMSO. It was observed that continuous photolysis of this

complex with $\lambda = 365-580$ nm light released NO with quantum yield, Φ (0.034−0.108 mol E^{-1}). A deoxygenated CH_3CN solution of $[Cr(NCCH_3)_5(NO)](PF_6)_2$ in the presence of excess of $[Fe(S_2CNEt_2)_2]$ resulted in a transfer of NO to the iron center on irradiation.

The chromium (III) nitrito complex trans-$Cr(cyclam)(ONO)^{2+}$ is a very promising photochemical precursor for nitric oxide delivery to physiological targets (Ostrowski et al., 2010). It was reported that visible wavelength excitation of this complex in solution containing thiol reductant such as the biological antioxidant glutathione (GSH) leads to permanent reaction even under anaerobic conditions, resulting in high quantum yield NO release. The nitric oxide formed under such conditions is sufficient, even at μM concentrations using a low-intensity light source, to activate the enzyme soluble guanylyl cyclase (sGC). It was also observed that photolysis of complex in the nM concentration range with a portable blue LED leads to vasorelaxation of porcine coronary arterial rings, a process which was attributed to the NO activation of sGC (Fig. 5.1).

Toneatto et al. (2010) investigated the ability of $[Cr(phen)_2(dppz)]^{3+}$ (where dppz = dipyridophenazine, and phen = 1,10-phenanthroline) associate with DNA and its use as photocleavage reagent for photodynamic therapy (PDT) was described. The dppz is a planar bidentate ligand having extended π system and it binds strongly to double strand oligonucleotides (ds-oligo) and plasmid DNA. Their intrinsic DNA binding constants was found to be $3.9 \pm 0.3 \times 10^5$ and $1.1 \pm 0.1 \times 10^5$ M, respectively. It was indicated that $[Cr(phen)_2(dppz)]^{3+}$ bound non-covalently to DNA, promoting the photocleavage of plasmid DNA under 457 nm exposure. The role of the excited state of $[Cr(phen)_2(dppz)]^{3+}$ was confirmed for damaging the DNA structure. It was reported that a combination of DNA, $[Cr(phen)_2(dppz)]^{3+}$ and light was

FIGURE. 5.1 Vasorelaxation via NO activation of sGC. *Adapted from Ostrowski, A.D., Deakin, S.J., Azhar, B., Miller, T.W., Franco, N., Cherney, M.M., et al., 2010. Nitric oxide photogeneration from trans-Cr (cyclam)(ONO)$^{2+}$ in a reducing environment. Activation of soluble guanylyl cyclase and arterial vasorelaxation. J. Med. Chem. 53 (2), 715−722. With Permission.*

necessary to induce such damage. The *Escherichia coli* may also be photoinactivated by irradiation in the presence of this complex. Thus, it was considered that $[Cr(phen)_2(dppz)]^{3+}$complex is a promising candidate for photocleavage of DNA with possible applications in photodynamic therapy.

Hagiwara et al. (2013) reported that photocatalytic water splitting activities of GaN:ZnO modified with tetraphenylporphyrinato-chromium(III) chloride (Cr-TPPCl) can enhance its photocatalytic activity. It can be used without decomposition in the photocatalytic splitting of water for 24 h. It was also revealed that photoluminescence intensity of GaN:ZnO was decreased by it with modification with Cr-TPPCl and also loading of NiO and RhOX cocatalysts. It was suggested that artificial photosynthetic water splitting could be achieved on GaN:ZnO photocatalyst (modified with various porphyrins) in presence of visible light. It was reported that apparent quantum efficiency of the dye-modified GaN:ZnO photocatalyst was 2.73% at 410 nm (RhOX (0.1 wt%), NiO (0.1 wt%)/Dye (0.5 wt%)/IrO_2(0.1 wt%)−GaN:ZnO).

The photophysics and photochemistry of $[(CO)_5CrC(OMe)Me]$ were investigated by McMohan et al. (2015). They could provide an unambiguous evidence for the photochemical formation of a long-lived, 18-electron metallaketene species, which was found to be capable of acting as synthetically useful intermediate. It was revealed that an intermediate metallacyclopropanone singlet excited state of Cr complex was detected with a lifetime of less than 100 ps.

DMSO > DMF > AC

Barbour et al. (2017) prepared some chromium(III) bis-arylterpyridyl complexes containing intraligand charge-transfer (ILCT) excited states. It was reported that these ILCT bands are tunable under UV and visible radiation by incorporating electron-donating and electron-withdrawing groups on the aryl ring. It was observed that absorption of $Cr(4'$-(4-methoxyphenyl)-2,2′:6′,2″-terpyridine)$]_2^{3+}$ was stronger in the visible region ($\varepsilon = 11{,}900$ and 5090 M^{-1} cm^{-1} at 450 and 500 nm) as compared to parent complex $[Cr(tpy)_2]^{3+}$ (where tpy = 2,2′:6′,2″-terpyridine) ($\varepsilon = 2160$ and 170 M^{-1} cm^{-1} at 450 and 500 nm), respectively.

Büldt et al. (2017) reported that meta-terphenyl unit substituted with an isocyanide group its two terminal aryls afforded a bidentate chelating ligand $(CNtBuAr_3NC)_3$. This ligand was found to stabilize chromium in its zerovalent oxidation state. The homoleptic $Cr(CNtBuAr_3NC)_3$ complex exhibited luminescence in solution at room temperature, with excited-state lifetime (2.2 ns) and as a result, it can find applicationas as earth-abundant sensitizer in dye-sensitized solar cells. The Cr(0) complex is a very strong photoreductant, because of its excited-state oxidation potential.

The synthesis and photophysical properties of an acidic, luminescent chromium(III) complex, $[Cr(H_2tpda)_2]^{3+}$ (where H_2tpda = 2,6-bis(2-pyridylamino)pyridine) was reported by Otto et al. (2018). It was observed that excitation of as-prepared complex at 442 and 782 nm resulted in strong

long-lived NIR luminescence in water and in acetonitrile, respectively. It was interesting to observe that deprotonation of the NH groups of this complex with a non-nucleophilic Schwesinger base in CH_3CN switched off the luminescence, while re-protonation with $HClO_4$ restores its emissive properties. Although its pK_a value of $\mathbf{2}^{\mathbf{3+}}$ in water was 8.8, even then deprotonation was not found reversible in the presence of hydroxide ions.

Huang et al. (2019) developed hydrophobic silicone loaded photoNORM polymer disks (PDs), which is photoactivated nitric oxide-releasing moiety (oxygen satble). The pohotoNORM is a new O-nitrito chromium(III) complex trans-[Cr(PetA)$(ONO)_2$](BF_4) (where PetA = 5,14-dimethyl-7,12-diphenyl-1,4,8,11-tetraaza-cyclotetradecane). They tried different silicone polymers with this photoNORM. It was observed that there is photouncaging of nitric oxide with 451 nm light from these systems. It was indicated that such ensembles can be used as implants providing a potential strategy for in vivo uncaging of NO at specific physiological targets triggered by tissue-transmitting NIR excitation.

Jiménez et al. (2019) prepared chiral resolution of a kinetically inert molecular ruby $[Cr(dqp)_2]^{3+}$ (where dqp = 2,6-di(quinolin-8-yl)pyridine), which displayed strong dual light emission at room temperature. It was reported that wrapped arrangement of this dqp chelating ligands around the Cr(III) provided a helical conformations (nonplanar), which leads to the diastereoselective assembly of chiral bis-tridentate monometallic Cr(III)-helix. It was revealed that circularly polarized luminescence (CPL) spectra had two polarized emission bands within the NIR region, which were attributed to characteristic metal-centered spin-flip $Cr(^2E \rightarrow {}^4A_2)$ and $Cr(^2T_1 \rightarrow {}^4A_2)$. A long excited-state lifetime of 1.2 ms with high quantum yield (5.2%) was observed in water at room temperature. Thus, $[Cr(dqp)_2]^{3+}$ can act an ideal sensitizer for the fabrication of enantiopure luminescent supramolecular energy-converting devices, which will open up new avenues for construction of polarized photonic devices and NIR-CPL materials using chiral Cr(III) chromophores based on earth-abundant metals.

Photochemical transformations of paramagnetic chromium(I) 1,3 bis(diphenylphosphino), $[Cr(CO)_4(Ph_2PCH_2CH_2CH_2PPh_2)]^+$ (where dppp = $Ph_2PCH_2CH_2CH_2PPh_2$) complex was studied in dichloromethane under by UV radiations (Luckham et al., 2019). It was observed that this complex $[Cr(CO)_4(dppp)]^+$ was transformed into trans-$[Cr(CO)_2(dppp)_2]^+$. It was also revealed that an intermediate isomer-$[Cr(CO)_3(\kappa^1\text{-dppp})(\kappa^2\text{-dppp})]^+$ complex was formed at low temperature (77−120 K) in presence of UV irradiation, which is photochemically transformed into trans-$[Cr(CO)_2(dppp)_2]^+$. This type of photoinduced reaction was found to be concentration-dependent, leading to a distribution of the three complexes ($[Cr(CO)_4(dppp)]^+$, trans-$[Cr(CO)_2(dppp)_2]^+$) and mer-$[Cr(CO)_3(\kappa^1\text{-dppp})(\kappa\ ^2\text{-dppp})]^+$.

The effects of an inversion center and ligand non-innocence was observed by Treiling et al. (2019) to tune the luminescence and photochemistry of excited state of $[CrN_6]$ chromophore $[Cr(tpe)_2]^{3+}$ (where tpe = 1,1,1-tris(pyrid-2-yl)ethane). The $[Cr(tpe)_2]^{3+}$ exhibited the longest luminescence lifetime ($\tau = 4500$ μs) for polypyridyl chromium(III) complex with a very high luminescence quantum yield ($\Phi = 8.2\%$) at room temperature. The tpe ligands were redox non-innocent in $[Cr(tpe)_2]^{3+}$. It was revealed that excited state redox potential and lifetime of this complex surpassed the classical photosensitizer $[Ru(bpy)_3]^{2+}$ (where bpy = 2,2′-bipyridine).

The photochemical functionalization of 2D and layered gray arsenic with chromium hexacarbonyl was studied by Sturala et al. (2019). They carried out covalent functionalization and exfoliation of arsenic rhombohedral under ultraviolet light irradiation in presence of chromium hexacarbonyl. Here, arsenic atoms were found to act as ligands on the central chromium. This modification can find applications in different fields such as sensors, electronics, energy devices, etc.

Two new chromium and manganese bimetallic nanoclusters, $[Cr_{8-x}Mn_x(OH)_{8-x}(H_2O)_x(OOCC_6H_5)_{16}, \quad x = 1.11]$ and $[Cr_4Mn_4O_4(OOCC_6H_5)_{12}\cdot 3CH_3CN\cdot H_2O]$, have been synthesized by Zhang et al. (2019) in a one-pot solvothermal reaction under visible irradiation. First cluster can produce an increased photocurrent and exhibited significant visible-light-driven photocatalytic activity for H_2 evolution in aqueous system. It also exhibited ultrahigh stability in both; acid and base aqueous solutions, making it an excellent synthon for preparing functional materials.

An ultrafast photochemistry of the $[Cr(NCS)_6]^{3-}$ complex was studied by Khvorost et al. (2020) upon excitation to the $^4T_2$ ligand field (LF) state in N,N-dimethylformamide (DMF) and dimethyl sulfoxide (DMSO). It was observed that vibrational relaxation occurs in 1−5 ps. It was also revealed that this $[Cr(NCS)_6]^{3-}$ complex in the 2E state also underwent intersystem crossing to the ground state in 85 ± 5 and 65 ± 5 ns in DMF and DMSO, respectively but only a small amount undergoes irreversible photochemical decomposition in case of electronically excited state. It was found that $[Cr(NCS)_6]^{3-}$ complex released single or double isothiocyanate ions followed by its photolysis in DMSO by the coordination of the solvent molecules.

Anzani et al. (2020) investigated the effect of magnetic field on phosphorescence lifetime, emission spectrum, and quenching of tris (1,10 phenantroline) chromium (III) complex by phenols. Changes in the emission spectrum and lifetime of the ($^2T/^2E$) states of $[Cr(phen)_3]^{3+}$ were observed in presence of an external magnetic field. It was observed that emission spectrum showed changes in their phosphorescent states (^2E and $^2T_1$ doublets); (split and shift), with enhanced emission of a band corresponding to the $^2T_1 \rightarrow {}^4A_{1g}$ transition located at 700 nm and decrease in intensity of the band located at 730 nm corresponding to $^2E \rightarrow {}^4A_{1g}$ transition. The phosphorescent lifetime for both these emission states was found to be about ∼70 μs in aerated

aqueous solutions at ambient temperature and a decrease was observed with increasing applied external magnetic field.

Wegeberg et al. (2021) reported that chromium(0) with chelating diisocyanide ligands exhibited very weak MLCT emission (in solution) at room temperature. The luminescence quantum yield of chromium(0) isocyanide complex was enhanced by almost double with a significant increase in the MLCT lifetime also. The pyrene units in the diisocyanide ligand backbone gives an enlarged π-conjugation system and strongly delocalized MLCT state, where nonradiative relaxation was less dominant although a redshift of the emission was there. Here, pyrene moiety is coupled electronically to chromium(0) complex core in the excited state, but this is not the case in the ground state. It was reported that luminescence lifetimes and quantum yields for this pyrenyl-decorated chromium(0) complex exhibited bell-shaped dependence on polarity of solvent, which indicated two counteracting effects governing the MLCT deactivation. These two effects were predominant in deactivation through:

- Direct nonradiative relaxation to the ground state following the energy gap in more polar solvents, and
- Energetically nearby lying metal-centered state in apolar solvents.

A highly luminescent spin-flip emitter with a quantum chemically predicted blue-shifted luminescence was reported by Reichenauer et al. (2021). It was observed that spin-flip emission band of the chromium complex $[Cr(bpmp)_2]^{3+}$ (where bpmp = 2,6-bis(2-pyridylmethyl)pyridine) shifted to higher energy from 780 to 709 nm. The photoluminescence quantum yields was increased to 20%, and a long excited state lifetimes (ms) could be achieved at room temperature in acidic D_2O solution. The photophysical and ground state properties (lifetime, quantum yield, redox potential, and acid/base) of as-prepared spin-flip complex incorporating an earth-abundant metal surpassed $[Ru(\alpha\text{-diimine})_3]^{2+}$ charge transfer complexes, (commonly employed in optical sensing and photoredox catalysis), which indicates a bright future of these molecular ruby analogs.

Bapsita et al. (2021) reported the participation of the excited states of $[Cr(TMP)_2dppz]^{3+}$ (where TMP = 3,4,7,8-tetramethyl-1,10-phenanthroline; and dppz = dipyrido[3,2-a:2′,3′-c]phenazine) in photoreactions of DNA. It was observed that interactions of its enantiomers with natural DNA or with oligodeoxynucleotides with varying AT content (0%−100%) resulted in quenching of its emission. It was revealed that relatively long-lived dppz-centered states was found there in the region between 350 and 400 nm after excitation; thus, yielding emissive metal-centered state. It has promising application in the field of photocatalysis and phototherapeutics.

Hou et al. (2021) prepared two hetero-binuclear complexes $[Cr(L)Cl(\mu_1\text{-}OAc)Ln(\mu_2\text{-}OAc)Cl(H_2O)]$ (Ln = Eu or Tb) by self-assembling of $Ln(OAc)_3 \cdot 6H_2O$ with the chromium(III)-complex precursor $[Cr(L)Cl(H_2O)]$,

which was formed from oxidation and coordination reactions of $CrCl_2$ and the Salen-type Schiff-base ligand N,N′-bis(3-methoxy-salicylidene)cyclohexane-1,2-diamine. It was attributed to effective Eu^{3+}-to-Cr^{3+} energy transfer. The [Cr(L)Cl(μ_1-OAc)Eu(μ_2-OAc)Cl(H_2O)] exhibited the highly improved Cr^{3+}-characteristic near-infrared (NIR) phosphorescence as compared to its terbium counterpart [Cr(L)Cl(μ_1-OAc)Tb(μ_2-OAc)Cl(H_2O)] or Cr(III)-complex precursor [Cr(L)Cl(H_2O)].

Boden et al. (2021) used high-level spectroscopic methods on highly luminescent chromium(III) complex $[Cr(ddpd)_2](BF_4)_3$ (where ddpd = N,N′-dimethyl-N,N′-dipyridine-2-ylpyridine-2,6-diamine), which was two near-IR emissive doublet states with of the order of lifetimes microseconds. A remarkable rise in the integrated emission intensity by more than 3 times was observed at <10 K.

Lee et al. (2021) synthesized a new ligand (1,10-phenanthrolin-5-amine, N-(2-fluorenylmethylene)) and formed UV activable photoCORMs with the $M(1)(CO)_4$ (M = Cr, Mo, and W. These compounds contain four COs bonded to the metal center with distorted octahedral geometry, and these CO can be released on UV light (365 nm). It was observed that chromium compound displayed the shortest half-life and shortest CO-releasing rate. These compounds exhibited potent cytotoxicity against two human colorectal cancer cell lines (HT-29 and HCT 116) and with strong photo-induced cytotoxicity and high selectivity.

Nassar and Ali (2021) synthesized four binuclear complexes $[Cr_2(CO)_2L_2]$, $[Mo_2O_4(L)_2]$ (2), and $[W_2O_4(L)_2]$ (3) $[Mo_2O_5(CO)L]$. H_2O from the reaction of $[M(CO)_6]$ (M = Cr, Mo and W) with 6,6'-(([1,1′-biphenyl]-4,4′ diylbis(azaneylylidene)) bis(methaneylylidene)) bis(2,4-dichlorophenol) (H2L) in THF. It was reported that magnetic measurements indicated diamagnetic properties for molybdenum and tungsten complexes, but paramagnetic character for chromium complex. It was revealed that H2L was coordinated as tetradentate ligand via two imine nitrogen and two deprotonated phenolic oxygen atoms. It was also observed that Schiff base ligand (H2L) and its complexes exhibited fluorescence properties and can serve potentially as photoactive materials.

5.3 Coordination compounds of molybdenum

Molybdenum was discovered by Carl Welhelm Scheele, a Swedish Chemist in 1778. It was found in a mineral known as molybdenite (MoS_2) and at that time, it was confused as a lead compound. Molybdenum was isolated later in 1781 by Peter Jacob Hjelm. Presently, molybdenum is mostly obtained from molybdenite, powellite ($CaMoO_4$) and wulfenite ($PbMoO_4$). Molybdenum is an element with given atomic number 42 and its symbol is Mo. It is placed in group 6 and period 5. Molybdenum does not occur as free metal on Earth; however, it is present in various oxidation states in form of different minerals.

It forms compounds in various oxidation states starting from II to VI. It is a silvery-white metal, which is ductile and highly resistant to corrosion.

The photochemical studies were reported for a series of M(CO),L complexes (where M = Cr, Mo, or W and L = 2,2′-bipyridine, 1.10-phenanthroline, or a derivative diimine ligand) by Manuta and Lees (1986). They observed low-energy LF and intense metal-to-ligand charge-transfer (MLCT) transitions in these complexes. It was observed that energy positions of the MLCT transitions were found to be extremely sensitive to solvent medium and the nature of ligand substituent. The photoreaction efficiencies depends on wavelength of irradiation; e.g., W(CO)(bpy) in benzene; LF excitation at X = 395 nm yields $\phi = 1.2 \times 10^{-5}$, whereas MLCT excitation at X = 514 nm yields $\phi = 5.4$ X. It was revealed that LF state was responsible for the photochemistry in these $M(CO)_4L$ complexes. The photoefficiencies following MLCT excitation (514 nm) were found to be slightly temperature-dependent, which indicated that the MLCT state is intrinsically photoactive or some another excited state is close in energy.

Szymańska-Buzar et al. (1995) reported that photochemical reactions in low-temperature matrix X (where X = Ar or CH_4) doped with molybdenum hexacarbonyl and an alkyne (HC≡CH, MeC≡CH, or MeC≡CMe) afforded corresponding alkyne complex of molybdenum pentacarbonyl, [(η^2-RC≡CR') $Mo(CO)_5$], [X … $Mo(CO)_5$] and CO. They also investigated photochemical interconversion of these three species [$Mo(CO)_6$], [X … $Mo(CO)_5$] and[(η^2-RC≡CR')$Mo(CO)_5$]. It was observed that a further irradiation ($\lambda = 313$ nm) caused the pentacarbonyl complexes to release one CO with the formation of tetracarbonyl species, while there was photoejection of CO at $\lambda = 369$ nm and formation of [(η^2-RC≡CR')$Mo(CO)_4$] (R,R′ = H,H or Me,Me).

The photochemistry of (η^6-arene)$Mo(CO)_3$ compounds (where arene = benzene, mesitylene, hexamethylbenzene, *or p*-xylene) was investigated by Breheny et al. (1998) using laser flash photolysis, matrix isolation and time-resolved infrared spectroscopy (TRIR). It was reported that the efficiency for photochemical expulsion of CO from (η^6-mesitylene)$Mo(CO)_3$ was dependent on wavelength of irradiation, which was found to be different from behavior of analogous (η^6-arene)$Cr(CO)_3$.

Fui et al. (2013) observed that mononuclear molybdenum complex with the general formula [MoTp*(NO)I(X)] (where Tp* = tris(3,5-dimethylpyrazolyl) hidroborate and X = 1,4-bis(pyridin-4-ylethynyl)benzene) exhibited properties of a photosensitizer in photoelectrochemical cell. It was observed that photoelectrochemical properties of TiO_2 photoelectrode sensitized by [MoTp*(NO)I(X)] gave positive photoinduced current as compared to unsensitize TiO_2photoelectrode.

Mark-Lee et al. (2013) reported that molybdenum dithiolene complexes [MoTp*(NO)(L)] (where Tp* = tris(3,5-dimethylpyrazolyl)hydroborate and L = toluene-3,4-dithiolate, 1,2-benzenedithiolate, or 3,6-dichloro-1,2-benzenedithiolate) exhibited the desired chemical and physical properties

as photosensitizer in a photoelectrochemical cell. It was revealed that all the three complexes had an energy band gap in the range of 1.45−1.48 eV, which falls in visible light region. It was reported that [MoTp*(NO)(L3)]-doped TiO_2 photoanode showed an enhanced photoinduced current as compared to undoped TiO_2 photoanode. It was also revealed that Cl atoms on the dithiolene group was responsible for a better interaction between TiO_2 photocatalyst and the photosensitizer molecule using halogen atom-induced chemical bonding.

A homoleptic Mo^0 complex with bidentate isocyanide ligands was reported by Büldt et al. (2016), which exhibited metal-to-ligand charge transfer (MLCT) luminescence with lifetimes and quantum yields almost similar to $Ru(bpy)_3^{2+}$(where bpy = 2,2′-bipyridine). It was observed that this Mo^0 complex is very strong photoreductant and it could reduce acetophenone. They revealed that this complex has a potential for its use in photoredox catalysis in rearrangement of acyl cyclopropane to a 2,3-dihydrofuran whereas strongly reducing Ir(2-phenylpyridine)$_3$ photosensitizer also cannot catalyze it because of highly negative reduction potential. They opened new avenues for use of Mo^0 complexes with chelating isocyanides with long-lived MLCT excited states that can find applications in photoredox chemistry.

Kirakci et al. (2014) synthesized two octahedral molybdenum cluster compounds $Na_2[Mo_6I_8(N_3)_6]$ and $Na_2[Mo_6I_8(NCS)_6]$ and studied their luminescent properties and biological activity. Most of the molybdenum clusters have low solubility in water and undergo hydrolysis along with sedimentation, aggregation and diminishing luminescence as well as singlet oxygen-sensitizing properties. These as-prepared compounds behaved in a different manner. They are soluble in water and also show red luminescence, which is quenched by molecular oxygen to produce singlet oxygen ($^1\Delta_g$) with high quantum yields. It was also reported that these $[Mo_6I_8(N_3)_6]^{2-}$ and $[Mo_6I_8(NCS)_6]^{2-}$complexes gradually hydrolyze but they do not form sedimentation, aggregation and there are luminescence properties also. Apart from it, quantum yields of singlet oxygen also remained unaffected.

Luo et al. (2016) prepared two polymolybdate-based complexes $(H_2L1)_2(Mo_4O_{13})$ and $(L2)_2(HL2)_2(Mo_8O_{25})\cdot 7H_2O$ (where L1 = 4-(5-((2H-1,2,4-triazol-3-yl)-2H-1,2,4-triazol-3-yl)pyridine) and L2 = 5-[4-(1 Himidazol-1-yl)-phenyl]-2H-tetrazole) via hydrothermal method. It was found that in first complex, one-dimensional (1D) $[Mo^V_4Mo^{VI}_4O_{26}]_\infty^{8-}$ chain was constructed by vertice-sharing of $\{MoO_6\}$ octahedra, while uncoordinated protonated $[H_2L1]^{2+}$ species are linked with different $[Mo_8O_{26}]_\infty^{8-}$ chains via supramolecular forces. In second complex $[Mo_8O_{25}]^{2-}$ moieties are linked by the μ_3-$[HL2]^+$ and μ_2-L2 ligands into 1D chain, which possesses more narrow band gap than first complex showing stronger photocurrent response as compared to first complex under the visible light (650 nm > λ > 350 nm). It was observed that the electroconductivity of the complex/graphene composite material in case of first complex on addition of graphene was much improved.

It exhibited much improved electrocatalytic activity for the evolution of H_2 reaction (HER) as compared to second one.

Martínez et al. (2016) investigated photo-assisted oxygen transfer to cyclohexene, 1-octene and cyclooctene. They used molecular oxygen as a primary oxidant using dichloro-dioxo-(4,4′-dicarboxylato-2,2′-bipyridine) molybdenum (VI) complex grafted on the surface of mesoporous TiO_2. It was observed that porosity of the support titania, as well as the amount and dispersion of the covalently anchored dioxo Mo(VI) complex strongly influenced the photocatalytic properties. It was reported that new hybrid Mo(VI) derivatized mesoporous TiO_2catalyst was found to be efficient in the photo-assisted oxygen transfer to different alkenes. The high stability of such catalyst was also confirmed by recycling studies.

Two complexes of molybdenum have been synthesized by Mitra and Sarkar (2016): $[NBu_4][MoO(bpy)(mnt)(SePh)]\cdot CH_2Cl_2$ and $[NBu_4][MoO(phen)(mnt)(SePh)]\cdot CH_2Cl_2$ (where bpy = 2,2′-bipyridine, phen = 1,10-phenanthroline, and mnt = maleonitriledithiolate ion). These were stabilized by aromatic diimine. These complexes generated superoxide radical under aerobic conditions is presence of sunlight (or tungsten lamp) in solution associated with the formation of paramagnetic Mo(V) species because of single electron transfer from the Mo(IV) complex to oxygen. The presence of Mo(V) under photo-irradiation was ascertained by EPR spectroscopy while generated superoxide radical was confirmed by nitrobluetetrazoleum (NBT) chloride test giving blue diformazan. The emission lifetime of phosphorescence of both these complexes was 6−8 μs.

Cheplakova et al. (2017) used nanosized mesoporous metal−organic framework MIL-101 (Matérial Institut Lavoisier) as nanocarrier for photoactive hexamolybdenum cluster compounds. They investigated hexamolybdenum cluster complexes for their possible use in biological and medical applications like singlet oxygen generation, luminescence, cytotoxicity, cellular uptake behavior, etc. It was also revealed that as-prepared materials were then used in living cells because of their low toxicity values. It was found that cluster supported on MIL-101 exhibited in vivo phototoxicity

A Schiff (Mo) based complex was prepared by Bian et al. (2018) supported on GO surface. Then it was combined with graphitic carbon nitride (g-C_3N_4) polymer (Mo-GO/g-C_3N_4) so that it becomes photoactive. The photocatalytic activity of as-prepared nanocomposite was evaluated under simulated sunlight (AM 1.5) for epoxidation of different olefin substrates. It was also revealed that both; metal active centers and GO can efficiently enhance electron transfer; thus, improving its catalytic performance.

Fogeron et al. (2018) synthesized two dithiolenes with a pyrazine ring fused with a pyran ring, which mimicked molybdopterin (MPT) present in the active site of formate dehydrogenases (FDHs). It was revealed that one mimicks MPT in the dihydropyrazine form while the other mimicks MPT in tetrahydropyrazine form, which is the more biologically relevant. Both these

complexes were duly characterized. The as-prepared $MoO(dithiolene)_2$ complexes catalyze the photoreduction of CO_2, where formic acid was obtained as the major product, and carbon monoxide with turnover number 100 in about 8 h.

Herr et al. (2019) reported that tris(diisocyanide)molybdenum(0) complexes have long-lived ^{3}MLCT (metal-to-ligand charge transfer) excited states. It was observed that complex of Mo was better as compared to $[Ru(2,2'\text{-bipyridine})_3]^{2+}$ with quantum yield (0.20), luminescence excited state lifetimes (microseconds) could be achieved at room temperature in solution. It was also revealed that such excited Mo(0) complexes are capable of inducing chemical reactions, which required precious metal-based photosensitizers. It was revealed that a robust Mo(0) complex exhibited stable photoluminescence and it was found to be photoactive on continuous irradiation for more than 2 months. It was indicated that Mo(0) complexes with diisocyanide chelate ligands, form a new family of luminophores, photosensitizers, which can be used as an alternate costly metal-based 4 d^6 and 5 d^6 complexes and to non-emissive Fe(II) compounds. Thus, it can be used for in lighting, sensing, and catalysis.

Ma et al. (2019) covalently decorated some molybdenum(VI/V) POM-based self-constructed complexes $[Mo^{VI}_{12}O_{24}(\mu_2\text{-}O)_{12}(trz)_6(H_2O)_6] \cdot 6Hma \cdot 18H_2O$, $[Mo^{VI}_{7}O_{14}(\mu_2\text{-}O)_8(trz)_5(H_2O)] \cdot 7Hma \cdot 5H_2O$, $Na_3[Mo^{V}_{6}O_6(\mu_2\text{-}O)_9(Htrz)_3(trz)_3] \cdot 7.5H_2O$ and $[Mo^{V}_{8}O_8(\mu_2\text{-}O)_{12}(Htrz)_8] \cdot 30H_2O$ (Where Htrz = 1*H*-1,2,3-triazole, ma = methylamine) with tri-coordinated deprotonated/protonated 1,2,3-triazoles. The channels were observed in first complex with an inner diameter of 7.5 Å, while a tunnel with inner diameter of 4.1 Å composed of stacking molecules was there in other complex. It is occupied by free disordered methylamines, showing selective adsorption of O_2 and CO_2 at 25°C. The last two complexes are fine adsorption materials with diversified pores for CH_4 and CO_2 under low pressure, while first two complexes exhibited reversible photoresponsive thermochromism. The photo-/thermoresponse properties of these as-prepared complexes offer a new pathway for the self-constructions of one-off hybrid materials having good properties of both; MOFs and POMs.

Two complexes mono-dithiolene complexes $[Mo(CO)_2(dt)(dppe)]$ and $[W(CO)_2(dt)(dppe)]$ [where dt = cyclohex-1-ene-1,2-dithiol; 5,6-dihydro-2*H*-pyran-3,4-dithiol and dppe = 1,2-bis(diphenylphosphino)ethane)] were synthesized by Elvers et al. (2019) by a photochemical procedure. It was reported that the typical basic deprotection of the dithiolene ligand precursor was replaced by a light-induced opening of the 1,2-dithiole-2-one moiety. Advantages of this method are; cleaner transformations, higher yields and the possibility to monitor the reaction progress continuously and precisely. It was revealed that the light induced pericyclic reaction of the protection group releases CO with formation of a 1,2-dithione, which can oxidize an electron rich metal precursor because of its non-innocent character.

A carbon monoxide-releasing material (CORMA) has been prepared by Silva et al. (2021). They incorporated molybdenum hexacarbonyl in a hafnium-based metal-organic framework (MOF) with the UiO-66 architecture. They adsorbed $Mo(CO)_6$ from solution to afford supported materials having 6.0−6.6 wt% Mo. It was revealed that both crystallinity and morphology of the porous host was not affected by the loading. They can behave as CORMAs and transfer CO to heme proteins, They used the standard myoglobin (Mb) assay method to test these materials. It was observed that encapsulated hexacarbonyl molecules in Mo(6.0)/UiO-66(Hf) liberated CO, when photoactivate with low-power UV light (365 nm) leading to a maximum amount of 0.26 mmol CO released per g of material, while it was found stable in dark.

Ultrafast photochemistry of molybdenum carbonyl-nitrosyl complex with a triazacyclononaneco ligand was studied by Gessner et al. (2021). They observed that transition metal complexes capable of releasing small-molecule messengers (carbon monoxide and nitric oxide) upon photoactivation can be used as an effective tools. It was reported that photodissociation of one CO ligand on UV excitation was there, but release of NO was not observed under similar conditions.

De la Torre et al. (2022) incorporated an ionic assembly of the hexanuclear molybdenum cluster compound $(Bu_4N)_2[Mo_6I_8(CH_3CO_2)_6]$ in amino-decorated mesoporous silica nanoparticles (MCM-41) affording molybdenum-based hybrid photosensitizer (1@MCM-41). As-prepared photoactive material had high porosity because of intrinsic high specific surface area of MCM-41 nanoparticles (989 $m^2\ g^{-1}$), and it provided a good dispersion of the hexamolybdenum clusters on the nanoparticles surface. It was reported that this hybrid photosensitizer can generate singlet oxygen efficiently, and it gave photooxygenation reaction of 9,10-anthracenediyl-bis (methylene)dimalonic acid (ABDA) in water. It was also revealed that a good activity of as-prepared hybrid photosensitizer was there in presence of LED light (15.6 mW/cm^{-2}) against human cervical cancer (HeLa) cells. It was observed that it reduced the viability up to 70% after 20 min irradiation, while there was low cytotoxicity in the darkness.

Quiñonez et al. (2022) reported selective oxygen atom transfer to α-pinene, β-pinene, camphene and (R)-limonene by dioxo-Mo(VI) Ln complex (where Ln = 2-aminothiazole-4-carboxylic acid) anchored on TiO_2 nanotubes (TiO_2-NT). Here, O_2 was used as an oxidant under UV light at ambient conditions. It was observed that the molecular oxygen reoxidizes the reduced (Mo(IV)═O) unit in the darkness, forming an intermediate oxo-peroxo-Mo. It was also revealed that catalyst under UV radiation transfers two oxygen atoms to the olefin and α-pinene was found to be the most reactive monoterpene.

The synthesis of chromium, molybdenum, tungsten, manganese, and iron complexes bearing N-heterocyclic carbene and carbonyl supporting ligands have been reported by Tang et al. (2022). The general formula of these complexes is $[ML(CO)_3X]$ or $[ML(CO)_3]$ (where X = CO or Br and

L = 1-phenyl-3-(2-pyridyl)imidazolin-2-ylidene). They studied photophysical properties of these complexes and revealed that there is decarbonylation, whenever these complexes were exposed to ultraviolet light. Here, CO ligand is replaced with a labile acetonitrile (solvent) molecule. The potential utility and applications of these complexes as visible-light-mediated photoredox catalysts and their capability to facilitate some photoinduced reactions was investigated through reductive or oxidative functionalization of organic molecules.

5.4 Coordination compounds of tungsten

Spanish chemists Juan José and Fausto Elhuyar made the discovery of tungsten in 1783, when they were dealing with samples of the mineral wolframite. The name "tungsten" is accepted from the old Swedish term for heavy stone. The element tungsten has an atomic number of 74 and its symbol is W. It belongs to group 6 (d^6). It exhibited oxidation states from II to VI.

The luminescence lifetimes have been determined by Rawlins et al. (1990) for W(CO)5(4-CNpy) and W(CO),(pip) complexes (where 4-CNpy = 4-cyanopyridine and pip = piperidine). It was reported that $W(CO)_5$,(4-CNpy) is a multiple-state emitter, which displayed dual emission bands and emitting levels are assigned to metal to ligand charge-transfer (MLCT) excited states with predominantly triplet character. It was also revealed that two MLCT emitting levels established a thermal equilibrium in solution, while the two radiative MLCT excited states are there in frozen glass, which are no longer thermally equilibrated. Luminescence spectra and lifetimes were also observed from $W(CO)_5$(pip) at low temperatures, and it was concluded that is a LF state with predominantly triplet character is responsible for emitting level. It was indicated that LF levels are populated on near-UV light excitation, and they can undergo efficient radiationless deactivation, which includes conversion to the emitting 'MLCT excited-state manifolds.

Ali and Kaur (1991) ligand field excitation of octacyano complexes of molybdenum(IV) and tungsten(IV) produced $[M(CN)_7OH]^{4-}$ and a free cyanide ion. This complex reacts with 1,2,3-indane-trione-hydrate in 1:1 stoichiometry. The rate constants and quantum yields were found to be maximum at pH 8.0. It was also revealed that rate of reaction and quantum yield increases with increase in the concentration of ligand, but decreases with $[M(CN)_8]^{4-}$ concentration. It was also indicated that quantum yields are higher for molybdenum complex as compared to tungsten complex due to shorter lifetime of the excited state species. This was attributed to physical deactivation, which is more rapid in the heavier element because was attributed to enhanced spin-orbit coupling. The molecular-orbital-induced splitting was also larger in $[W(CN)_8]^{4-}$ than in $[Mo(CN)_8]^{4-}$resulting in greater bond strength for tungsten.

Schoch et al. (1996) studied photophysics of some tungsten and molybdenum arylcarbyne complexes $Cp(CO)\{P(OMe)_3\}M{\vdots}C{-}Ar$ (where M = W, Ar = phenyl; o-tolyl; and, M = W, Ar = 2-naphthyl). It was indicated that the lowest excited state of these arylcarbyne complexes is based on a d(M) → π*(M⋮C−Ar) configuration and they displayed a weak, mid-visible absorption band attributed to the d → π* transition. Out of these, the tungsten complexes exhibited red luminescence with a lifetime in the 100−200 ns range. It was also revealed that arylcarbyne complexes had a strong transient absorption with a maximum in the 400−450 nm.

El-Medani et al. (2005) reported that sunlight irradiation of $[M(CO)_6]$, (where M = Cr, Mo and W) with N-salicylidene-2-hydroxyaniline (shaH2) or bis-(salicylaldehyde) phenylenediimine (salphenH2) in tetrahydrofuran afforded complexes with molecular formula $[Cr(shaH2)_3]$, $[MoO_2(shaH2)_2]$, & $[W_2O_5(shaH)_2]$ and oxo complexes [CrO(salphenH2)], $[Mo_2O_6(salphenH2)_2]$, and $[W_2O_6(salphenH2)]$. It was revealed that visible bands are due to ligand-to-metal or metal-to-ligand charge transfer.

Rimmer et al. (2010) reported a photoactivated carbon monoxide releasing moiety (photoCORM), $[W(CO)_5(TPPTS)]^{3-}$, which is air-stable and water-soluble tungsten(0) carbonyl complex of trianionic ligand tris(sulphonatophenyl)phosphine. It was reported that aqueous buffer solution of this complex had high quantum yield release of a single CO on near-UV photolysis. It was also observed that additional CO was slowly released from the $[W(CO)_4(H_2O)(TPPTS)]^{3-}$ photoproduct in aerated media due to autoxidation of tungsten center. It was revealed that first complex can serve as a carbon monoxide releasing moiety in primary photochemical reaction as well as in the secondary reactions of initially formed photoproduct.

Arifin et al. (2013) investigated optical and photoelectrochemical properties of TiO_2 thin film electrode doped with a new variation of ruthenium−(4,4′dimethyl-2,2′-bipyridine)−isothiocyanato−tungsten[bis-(phenyl-1,2-ethilenodithiolenic)] bimetallic complex (BM). Physical adsorption process was to immobilize the BM on the TiO_2 thin film. They used N3 commercial dye used as a dopant for the TiO_2 films. It was found that light absorption of the TiO_2 thin film doped with BM was better as compared to TiO_2 doped with the N3 commercial dye. It was reported that photocurrent of TiO_2 doped with the BM electrode was more as compared to TiO_2 doped with the N3 dye in the initial stage of illumination, but its performance was slowed down after a while. It was claimed that optical properties of as-prepared BM has potential application as dye sensitizer in a photoelctrochemical (PEC) cell.

Koutsouri and Mitsopoulou (2016) observed homogeneous photocatalytic hydrogen evolution using prismatic symmetric tris−dithiolene complexes of tungsten as reductive catalysts. These are $[W(S_2C_2(Ph)_2)_3]$ and its monoanion $[W(S_2C_2(Ph)_2)_3]$. It was reported that photocatalytic system consisting of $[ReBr(CO)_3(bpy)]$ triethanolamine and acetic acid as photosensitizer

sacrificial electron donor and proton source, respectively. Although the activity of this photocatalytic system was lower (TON = 18), but it indicated that the homoleptic tris-dithiolene complexes can be used as proton reductive catalysts and its monoanion form was found to be more active.

Yeung et al. (2017) reported synthesis and applications of two series of air-stable luminescent tungsten(VI) complexes. It was observed that these tungsten(VI) complexes show phosphorescence in the solid state and also in solutions with emission quantum yields (up to 22%) in thin film (5% in mCP) at room temperature. It was also indicated that a complex with 5,7-diphenyl-8-hydroxyquinolinate ligand displayed fluorescence (blue−green) and phosphorescence (red) with comparable intensity, which could be used for ratiometric luminescent sensing. It was also found that solution-processed organic light-emitting diodes based on one of the complex showed a stable yellow emission with an external quantum efficiency (EQE) and luminance up to 4.79% and 1400, cd m^{-2}, respectively. They also applied these tungsten(VI) complexes in light-induced aerobic oxidation reactions.

Huckaba et al. (2018) synthesized (pyridyl)-N-heterocyclic carbene tungsten tetracarbonyl complex, [W(pyNHC)$(CO)_4$]. It was then used as a pre-catalyst for photocatalytic generation of hydrogen. It was reported that in situ generated catalyst [W(pyNHC)$(CO)_3$] for production of H_2 in the presence of triflic acid, decamethylferrocene and visible-light without using any photosensitizer. A turnover number (TON) of more than 17 was observed in 3 h for the production of hydrogen with this system, which is better as compared to homogeneous photocatalyst using visible light (4 TON) reported earlier.

Peschel et al. (2019) synthesized four tungsten alkyne complexes coordinated by the bio-inspired S,N-donor ligand 2-(4′,4′-dimethyloxazoline-2′-yl) thiophenolate (S-Phoz). Earlier, a reaction of the respective alkyne with the bis-carbonyl precursor [$W(CO)_2$(S-Phoz)$_2$] was used for preparing such complexes [W(CO)(C_2R_2)(S-Phoz)$_2$] (where R = H, Me, and Ph). It was reported that oxidation with pyridine-N-oxide gave W-oxo species [$WO(C_2R_2)$(S-Phoz)$_2$], which were found to release alkyne upon light irradiation affording this five-coordinated complex [WO(S-Phoz)$_2$].

Fajardo et al. (2019) carried out base-promoted homolytic aromatic substitution of 1-(2-iodobenzyl)-pyrrole in deuterated benzene catalyzed by W$(CNAr)_6$ (where CNAr = arylisocyanide) photoreductants. It was observed that moderate to high efficiencies has a correlation with W$(CNAr)_6$ excited-state reduction potentials on one-photon excitation (445 nm) with 10 mol % loading of the most powerful photoreductants W$(CNDipp)_6$ and W$(CNDipp\text{-}PhOMe_3)_6$ (where $CNDippPhOMe_3$ = 4-(3,4,5-trimethoxyphenyl)-2,6-diisopropylphenylisocyanide), which afforded almost complete conversion. It was found that photocatalysis can be driven with femtosecond-pulsed excitation (810 nm) using two-photon absorption (TPA) cross sections of W$(CNAr)_6$ complexes. The photocatalysis for one- and two-photon excitation both was terminated by the formation of seven-coordinate [$W_{I2}(CNAr)_5$]

complex. It was also reported that $W(CNDipp)_6$ can be regenerated again by chemical reduction of $W_{I2}(CNDipp)_5$with excess ligand present in solution.

Wang et al. (2021) reported phenomenon in coordination-promoted photoluminescence (CPPL) of organometallic complex, tBu(ONO). Here, ligand is tBu(ONO) and metal is tungsten. A weak photoluminescence of ligand tBu(ONO) was attributed to destroyed planarity because of configuration twisting in the excited state. But, coordination bond formed between tBu(ONO) and the metal tungsten in this complex changes the two twisted parts of tBu(ONO) into an almost planar configuration. It was reported that excited state configuration many have some configurational changes but the coplanarity of tBu(ONO)−W has not been distrubed. As a result, photoluminescence of tBu(ONO)−W is enhanced as compared to ligand tBu(ONO). It was revealed that coordination effect between the ligand and the metal inhibited the configuration twisting of ligands; thus, promoting light emission. It was also found that the emission peaks of tBu(ONO)−W are due to the relaxation of ILCT and LMCT states. Such a photoluminescence performance based on regulation of metal-ligand coordination bonds provided a newer strategy for designing high-performance luminescent materials.

Barth et al. (2022) observed $W(CNDipp)_6$ catalyzed photochemical cyclization of 1-(2-iodobenzyl)-pyrrole (IBP) and 1-(2-bromobenzyl)-pyrrole (BBP) to 5H-pyrrolo[2,1-a]isoindol catalyzed in 1,2-difluorobenzene (DFB). It was observed that 78% of IBP (50 mM) was converted to product after 1 h (16 turnovers) on irradiating $W(CNDipp)_6$ (5 mol %) in DFB solution at 445 nm. A fast photoinduced disappearance of $W(CNDipp)_6$was found on adding tetra-n-butyl ammonium hexafluorophosphate (TBAPF6) (0.2 M) to the DFB solution, but it did not inhibit photochemical cyclization of IBP, which indicated that IBP cyclization could also be driven by a nonluminescent photocatalyst.

The photochemical properties of complexes of chromium, molybdenum and tungsten are quite interesting involving different transitions and therefore, they can find some interesting applications in the field of sensors, electronics, energy devices, photodynamic therapy, release of NO and CO, etc., but much more is to be done before such applications come really into practice. Some more future applications will be available in near future.

6.1 Introduction

It is known that precious metal complexes with valence electron configuration d^n normally exhibit luminescent metal-to-ligand charge transfer (MLCT) excited states and they can find numerous applications in the field of lighting, solar cells, sensing, and synthetic photochemistry. A lot of attention has been received by iron(II) as a possible Earth-abundant alternative to these precious metal, but till date no iron(II) complex has been reported to exhibit MLCT emission on continuous-wave excitation. The manganese(I) has also electron configuration similar to iron(II), but till now, it has been overlooked in the search for low cost MLCT luminophores. Photochemical and photophysical properties of coordination compounds make them useful in varied fields such as imaging, sensing, catalysis, photodynamic therapy, etc. Group 7 contains elements manganese, technetium and rhenium. Out of these, photochemical behavior of technetium has not been much explored because of its radioactive nature. Its complexes are also not much stable for study; however, coordination compounds of manganese and rhenium have found numerous applications.

6.2 Coordination compounds of manganese

Johann Heinrich Pott (1740) reported a new element as manganese. He was able to prepare potassium permanganate, which is one of the strongest oxidizing agents known. The name manganese was carried from two routes: (i) from the Latin "magnes", meaning magnet, or (ii) from the black magnesium oxide, "magnesia nigra". Black ore of manganese, pyrolusite (manganese

dioxide, MnO_2) was used by cave painters of the Lascaux region of France around 30000 years ago. Now, it is used by glass makers for removal of pale greenish tint of natural glass.

- Manganese is a hard, brittle and silvery metal. It is mainly used in alloys, such as steel (1% manganese).
- To increase its strength, workability and resistance to wear.
- Manganese steel contains about 13% manganese. It is extremely strong and therefore, it is used for safes, railway tracks, prison bars and rifle barrels.
- Drinks cans are resistant to corrosion as these are made of an alloy of aluminum with 1.5% manganese.
- Manganese is the fifth most abundant metal in the crust of Earth.
- Nodules of manganese are found on the floor of the oceans containing approx. 24% manganese; of course with smaller amounts of other elements.
- The enzyme responsible for converting water molecules to oxygen during photosynthesis contains four atoms of manganese.
- The average human body contains about 12 mg of manganese. It is also essential for utilization of vitamin B_1. About 4 mg of manganese is required and it is supplied from nuts, bran, wholegrain cereals, parsley, and tea. The bones grow spongier and break more easily with deficiency of manganese.
- Its atomic number is 25 and its electron configuration is [Ar] 3 d^5 $4s^2$, and it belongs to group 7.
- Its exist in various oxidation state as +7, +6, +5, +4, +3, +2, 0 and sometimes −1 also.

Kokkes et al. (1985) reported photolysis of several complexes $(CO)_5MM'(CO)$, (a-diimine) (where M, M′ = Mn, Re) in 2-MeTHF at temperatures in the range 133−230 K. It was observed that homolysis of the metal-metal bond occurred for the complexes with M = Mn and M′ = Mn, Re above 200 K, but the main products of the reaction were [M(CO),]- and [M′(CO), (a-diimine)(2-MeTHF)]* (if M = Mn, Re and M′ = Mn) at temperatures below 200 K. The ions were not formed by direct heterolysis of the metal-metal bond but through thermal disproportionation of a photosubstituted product $(CO)_5MM'(CO_2)$ (a-diimine)(2-Me-THF). It was revealed that corresponding $(CO)_5MnRe(CO)_3$(a-diimine) ones (where M = Mn, Re and M′ = Mn) did not show photosubstitution of CO but breaking of a metal-nitrogen bond on photolysis at temperature 133 K. It was also proposed that the primary photoprocess at lower temperatures is bond breaking is and it is followed by release of CO (where M′ = Mn).

Stufkens et al. (1991) revealed that photochemistry of irradiation of $(CO)_5MnMn(CO)_3$(α-diimine) complex, where $Mn(CO)_5$ and $Mn(CO)_3$(α-diimine) radicals were formed, which undergo radical coupling and electron transfer (chain) reactions. A relationship has been proposed for halide

complexes $XMn(CO)_3(\alpha\text{-diimine})$ (where X = Cl, Br, and I), which undergo homolysis of Mn-X bond on irradiation. It was also reported that $(CO)_5MnMn(CO)_3(\alpha\text{-diimine})$ and $XMn(CO)_3(\alpha\text{-diimine})$ exhibited similarity in their photochemical behavior as both of them formed the dimeric species $Mn_2(CO)_6(\alpha\text{-diimine})_2$ upon irradiation into their lowest-energy absorption band.

The fac-Mn(Cl) (CO_3) (H-DAB) has low-energy Mn−3d to 1,4-diaza-1,3-butadiene (H-DAB) π^* metal-to-ligand charge transfer (MLCT) excited states, which are not Mn−CO dissociative by their electronic nature (Rosa et al., 1996). It was also reported that loss of an equatorial CO ligand upon MLCT excitation can be explained by a radiationless transition from the MLCT states to this ground state. The complex will undergo a strong rearrangement (structural) upon equatorial CO dissociation, where chloride shifts to an equatorial open site. This rearrangement explained the formation of mer-$Mn(Cl)(CO)_3(\alpha\text{-diimine})$ complexes on back-reaction of their CO-loss product with CO. The equatorial CO dissociation is quite different from the normal photochemical dissociation from the dissociative ligand-field state or through crossing of the photoactive excited state by this ligand-field state. On the other hand, axial CO dissociation, which does not occur ordinarily and it does not give rise to rearrangement (structural), but predicted to produce the fac-complex upon back-reaction with CO.

Carlos and Neumann (2000) reported photoreactions resulting from metal-to-ligand charge transfer (MLCT) excitation of the manganese(I) tricarbonyl complexesfac-$[Mn(CO)_3(phen)(Im)](SO_3CF_3)$ and fac-$[Mn(CO)_3(phen)(Im\text{-}CH_3)](SO_3CF_3)$ in different solvents at a wide range of wavelengths. The reaction product was found to be corresponding mer-$[Mn(CO)_3(phen)(Im\text{-}L)]^+$ isomer. The high quantum yields ($\sim$0.66 mol E^{-1}) indicated primary photoprocesses from ligand-field states. It was also reported that these complexes were luminescent even at room temperature and this emitting state can be tuned from an MLCT emission to intra-ligand (IL) fluorescence with variation in polarity of solvent and wavelength of excitation.

Carlos et al. (2004) observed photochemical and photophysical preparation of a series of fac-$[Mn(CO)_3(phen)(Im\text{-}R)](SO_3CF_3)$ complexes (where phen = 1,10-phenanthroline and Im = imidazole). It was reported that intra-ligand and metal-to-ligand charge transfer (MLCT) transitions were observed in the electronic absorption spectra of these complexes, which depends on nature of the ligand substituents. It was revealed that the emission spectra show an MLCT to highly structured π-π^* emission at room temperature on going from R = H, CH_3, C_6H_5, to Metro, (where metro = 2-methyl-5-nitroimidazole). The trend in photophysical and photochemical properties in the emission spectra was found to be same with the changes in the electron-donating or electron-withdrawing power of the substituent on the imidazole ligand. It was revealed that MLCT irradiation of the complexes with R = H, CH_3 resulted in formation of mer-$[Mn(CO)_3(phen)(Im\text{-}R)]^+$ isomers, while

complexes with the imidazole ligand substituted by C_6H_5 or metro release the Im-R ligand forming stereoretentive fac-$[Mn(CO)_3(phen)(S)]^+$ complexes.

Doux et al. (2005) prepared fac-$[Mn(SPS)(CO)_3]$ by reacting $[Mn(CO)_5Br]$ with lithium salt of the anionic SPS pincer ligand composed of a central hypervalent λ^4-phosphinine ring bearing two ortho-positioned diphenylphosphine sulfide side arms. It was reported that this isomer can be converted photochemically to mer-$[Mn(SPS)(CO)_3]$, with a very high quantum yield (0.80 ± 0.05) (Fig. 6.1). It was observed that both these isomers exhibited but luminescence from a low-lying ^{3}IL (SPS-based) excited state, but light emission of fac-$[Mn(SPS)(CO)_3]$ was quenched by the efficient photoisomerization, may be due to a low-lying Mn−CO dissociative excited state.

Three acylhydrazidate-containing complexes $[Zn(N_2H_4)(dphkh)]\cdot H_2O$ (where, dphkh = 4,4′-diphthalhydrazidatoketone hydrazone), $[Zn(npth)_2]$ (npth = naphthalhydrazidate) and $[Mn(mpdh)_2(H_2O)_2]\cdot 2H_2O$, were prepared by Wang et al. (2013a) via hydrothermal in situ acylation of N_2H_4 with aromatic polycarboxylic acids. It was reported that first compound is a layered Zn^{2+} coordination polymer with a mixed ligand of hydrazine and dphkh. Second compound is a unique example of a npth-extended coordination polymer, which exhibited a double-chain structure. It was revealed by solid-state photoluminescence analysis that first compounds exhibited strong luminescence with the maximum at 490 nm.

Bikas et al. (2014) prepared mixed-metal dicyanoargentate-bridged coordination polymers of Ag(I)−Mn(II). It was reported that coordination polymer 2D-$[Mn(\mu\text{-}L^1)(Cl)(\mu\text{-}NCAgCN)Mn_{0.5}(CH_3OH)]_n$, 1D-$\{[Mn(L^2)(Cl)(\mu\text{-}NCAgCN)Mn_{0.5}(CH_3OH)]CH_3OH\}_n$ and $[Mn(L^3)(Cl)(\mu\text{-}NCAgCN)Mn_{0.5}(CH_3OH)]_n$ were produced by reaction of manganese(II) chloride and potassium dicyanoargentate(I) with (X)(pyridin-2-ylmethylene)isonicotinohydrazide ligands (where HL^1 X = Ph, HL^2 X = Me, HL^3 X = H in good yields. Variable temperature magnetic

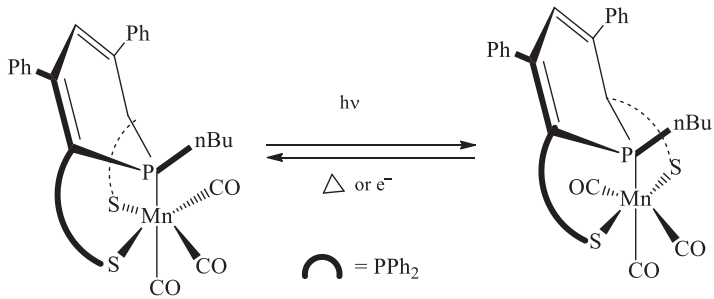

FIGURE. 6.1 A reversible change in fac-$[Mn(SPS)(CO)_3]$ complex. *Adapted from Doux, M., Mézailles, N., Ricard, L., Le Floch, P., Vaz, P. D., Calhorda, M.J., et al., 2005. Syntheses, X-ray structures, photochemistry, redox properties, and dft calculations of interconvertible f ac-and m er-[Mn (SPS)(CO)$_3$] isomers containing a flexible SPS-based pincer ligand. Inorg. Chem 44 (25), 9213−9224. With Permission.*

susceptibility measurements showed that despite the long distance among the high spin Mn(II) ions [10.4676(12) and 10.522(1) Å, respectively], weak antiferromagnetic coupling takes place through the long NC—Ag—CN bridge. Their photoluminescence behavior was also studied. The first compound exhibited a broad emission centered around 450 nm with two excitation maxima at 270 and 310 nm.

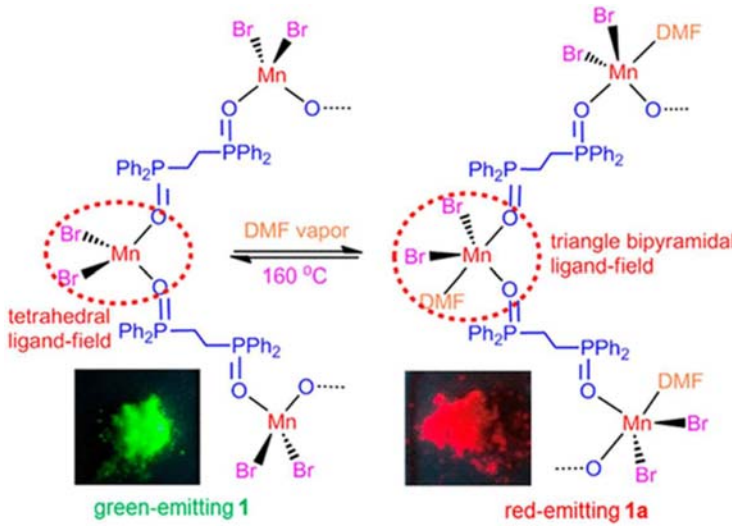
Fodor et al. (2016) reported that Mn(III) porphyrins are weakly emissive, but the fluorescence displayed by Mn(III) complexes with the cationic $TMPyP^{2+}$ ligand (where H_2TMPyP^{4+} = 5,10,15,20-tetrakis(1-methylpyridinium-4-yl) porphyrin) as well as its other alkyl derivatives (where alkyl = hexyl and dodecyl) were strong enough. It was also observed that elongation of the alkyl chain increased both; quantum yield as well as lifetime of the emission for the Mn(III) porphyrins. It was revealed that these cationic metalloporphyrins were used in a photocatalytic system with triethanolamine (TEOA) and methylviologen (MV^{2+}) as a sacrificial electron donor and acceptor, respectively. The outer-sphere photoinduced reduction of the metal center was there through quenching of the triplet excited state of these metalloporphyrins by TEOA. It was observed that there manganese(II) porphyrins were photoactive and an electron was transformed to MV^{2+} upon irradiation; thus, regenerating the starting complex. It was reported that as the alkyl substituents was increased, the quantum yield of the formation of methylviologen radical ($MV^{\bullet+}$) was also increased, but there was a considerable decrease in the durability of the photocatalyst. It was also found that anionic micelles totally hindered the photoinduced generation of Mn(II) porphyrins, but cationic micelles increased the efficiency of the accumulation of $MV^{\bullet+}$ significantly.

Reade et al. (2017) investigated the photochemical behavior of two metal-organic frameworks (MOFs) (single crystals) $\{Li_2(DMF)_2$ [(2,2′-bipy-5,5′-dicarboxylate)$Re(CO)_3Cl]\}_n$ (RELI) or $\{Li_2(DMF)_2$[(2,2′-bipy-5,5′-dicarboxylate)$Mn(CO)_3Br]\}_n$ (MNLI) reaction. These were prepared by the reaction of Re(2,2′-bipy-5,5′-dicarboxylic acid)$(CO)_3Cl$ or Mn(2,2′-bipy-5,5′-dicarboxylic acid)$(CO)_3Br$ with LiCl or LiBr, respectively, produces single crystals of. It was revealed that rhenium-containing MOF (RELI) exhibited luminescence and the excited state behavior is quite close in behavior of unsubstituted [Re(bipy)$(CO)_3Cl$], rather than a related MOF, where Li(I) cations are replaced by Mn(II) cations. It was also revealed that MNLI formed a dicarbonyl species, which rapidly recombined upon excitation with the dissociated CO, similar to photoejected CO not escaping the MOF channels.

Wei et al. (2018) prepared two novel tetrahedral manganese(II) complexes; (N-methylpiperidinium)$MnCl_4$ and (N-methylpyrrolidinium)$MnCl_4$. These complexes exhibited distinct fluorescence characteristics through organic cation modulation. The first complex showed prominent green luminescence with a high quantum yield (79.37%) while second complex emitted unusual red emission at 611 nm.

Wu et al. (2018) reported that reactions of $MnBr_2$ and ethane-1,2-diylbis(diphenylphosphine oxide) ($dppeO_2$) in dichloromethane−methanol solutions gave colorless crystals; $[MnBr_2(dppeO_2)]_n$, $[MnBr_2(dppeO_2)(DMF)]_n$, $[Mn(dppeO_2)_3][MnBr_4]$, and $Mn_2Br_4(dppeO_2)_2$, which depend on the conditions of crystallization. First two compounds displayed one-dimensional chain structures, which is composed of Mn(II) ions linked by bridging $dppeO_2$ with tetrahedral or trigonal-bipyramidal geometry, while the last one exhibited a cyclic dinuclear structure with two Mn(II) centers bridged by double $dppeO_2$ to have tetrahedral geometry. The third compound consisted of octahedrally coordinated cation $[Mn(dppeO_2)_3]^{2+}$ and tetrahedrally arranged anion $[MnBr_4]^{2-}$. It was found that first and last complexes were crystalline and these are highly luminescent with green emission bands centered (510 nm) on exposure of first complex to N,N-dimethylformamide vapor, while third compound showed intense orange luminescence (594 nm). A green emission (510 nm) was converted to red luminescence (630 nm), which was attributed to the formation of DMF-coordinated compound with a trigonal-bipyramidal ligand field (Fig. 6.2). It was also revealed that red-emitting 1a compound could be reverted to the original green-emitting 1 form with a tetrahedral ligand field upon heating at 160°C, and this reversible conversion could be repeated many times.

A new 3-position substituted imidazo[1,2-a]pyridine ligand, (E)-4-(3-(2-chloroimidazo[1,2-a]pyridin-3-yl)acryloyl)benzoic acid (HL) was synthesized by Li et al. (2018). Two new coordination polymers, $[ML_2(H_2O)]_n$



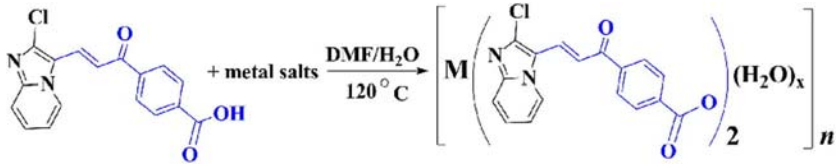


FIGURE. 6.2 Conversion of green emission to red-emission. *Adapted from Wu, Y., Zhang, X., Xu, L.J., Yang, M., Chen, Z. N., 2018. Luminescent vapochromism due to a change of the ligand field in a one-dimensional manganese (II) coordination polymer. Inorg. Chem. 57 (15), 9175−9181. With Permission.*

(M = Zn, and Cd) and one discrete complex, $MnL_2(H_2O)_4$, were synthesized using this ligand under the solvothermal conditions. Among these, first two coordination compounds are isostructural and show one-dimensional chain structures. The third complex was assembled into a dimer structure via supramolecular interactions. They also investigated photoluminescent properties of HL ligand and these coordination compounds.

Yue et al. (2019) synthesized eight new coordination compounds by incorporating a semi-rigid ether-based unsymmetrical tetracarboxylic acid (where H_4detc = 2,3,3′,4′-diphenyl ether tetracarboxylic acid) with various ancillary dipyridyl ligands (where phen = 1,10-phenanthroline, bipy = 4,4′-bipyridine, bpea = 1,2-bis(4-pyridyl)ethane, and bpee = 1,2-bis(4-pyridyl) ethylene), via hydrothermally technique. It was reported that $[Mn(H_2detc)(phen)_2]\cdot H_2O$ is a supramolecular networks built from binuclear structures.

Bortoluzzi et al. (2020) prepared manganese(II) tetrahedral complexes having general formula $[MnX_2L_2]$ (where X = Cl, Br, I; and L = 1,3-dimethyl-2-phenyl-1,3-diazaphospholidine-2-oxide). It was reported that these three species are quite luminescent in the green region, when excited with UV light. It was also observed that luminescence lifetimes strongly depend on coordinated halide. It was also revealed that photoluminescence was improved with this rigid 1,3-diazaphospholidine-2-oxide moiety as compared to phenylphosphonic diamide Mn(II) derivatives.

Manganese tricarbonyl complexes have a potential as catalysts for reduction of CO_2, but these complexes are normally photosensitive and are decomposed rapidly in presence of visible light. Henke et al. (2020) reported photochemical studies probe the initial steps of light-driven speciation for $Mn(CO)_3(^{R}bpy)Br$ complexes bearing a range of 4,4′-disubstituted 2,2′-bipyridyl ligands (where R = ^{t}Bu, H, CF_3, and NO_2). It was found that $Mn(CO)_3(^{NO}{}_2bpy)Br$ complex is unique in nature in all these compounds, which has a long-lived excited state and it does not undergo CO release or subsequent solvent coordination. It was also revealed that kinetics of photolysis and solvent coordination for light-sensitive complexes depend on electronic properties of the disubstituted bipyridyl ligand. It was indicated that metal-to-ligand charge-transfer (MLCT) and dissociative ligand-field (d−d) excited states both play a role in the ultrafast photochemistry (Fig. 6.3). It was also suggested that more robust catalysts could be prepared by designing

FIGURE. 6.3 Effect of substitution on MLCT and CO ligand loss in Mn complexes. *Adapted from Henke, W.C., Otolski, C.J., Moore, W.N., Elles, C.G., Blakemore, J.D., 2020. Ultrafast spectroscopy of [Mn (CO)$_3$] complexes: tuning the kinetics of light-driven CO release and solvent binding. Inorg. Chem. 59 (4), 2178–2187. With Permission.*

complexes, which avoid crossing between the excited states that drive photochemical loss of CO.

Herr et al. (2021) reported that isocyanide chelate ligands can form air-stable manganese(I) complexes, which exhibited MLCT luminescence in solution at room temperature. It was reported that these complexes can be used as photosensitizers for energy- and electron-transfer reactions and also promote the photoisomerization of trans-stilbene. It was revealed that electron transfer photoreactivity was from the emissive MLCT state, while the triplet energy transfer photoreactivity was due a ligand-centered $^3\pi-\pi^*$ state.

A cadmium coordination polymer assembled with aminopyrazine (ampyz) and acetate (AcO) is a high-efficiency material, which is able to convert ultraviolet radiation into blue light (with internal and external photoluminescence quantum yields of about 80%). Lemes et al. (2021) prepared a blue-light-emitter by just replacing the toxic cadmium element for Mn^{2+} and an isostructural Mn^{2+}coordination polymer was obtained. It was revealed that low-frequency radiative decay occurred before the target luminescence, which reduced much of its blue-light-emission efficiency not exceeding 3%.

Bortoluzzi et al. (2021a) synthesized tetrahedral Mn(II) bromo- and iodo-complexes with phosphoramidate and phosphonate ligands. They could prepare these mononuclear complexes, $[MnX_2L_2]$ by using monodentate ligands, $O{=}P(OPh)_2(NMe_2)$ and $O{=}P(OPh)_2Ph$. The bidentate resorcinol derivative $1,3\text{-}O{=}P(NMe_2)O{-}C_6H_4{-}O(NMe_2)_2P{=}O$ behaved as a bridging ligand, and afforded dinuclear complex by reaction of coordination polymer with MnX_2

salts, in the case of X = Br and I, respectively. It was reported that all these compounds showed green photoluminescence of Mn(II) in a tetrahedral environment, while complexes with $O{=}P(OPh)_2(NMe_2)$ in the coordination sphere displayed high photoluminescence quantum yields.

Bortoluzzi et al. (2021b) synthesized manganese(II) halide complexes using ligand, N,N,N′,N'-tetramethyl-P-naphtalen-2-ylphosphonic diamide from anhydrous MnX_2 salts (where X = Cl, Br, and I). It was revealed that slightly distorted tetrahedral geometry of the coordination sphere was there. The photoluminescence spectra exhibited superimposition of a green emission, related to the $^4T_1(^4G) \rightarrow {}^6A_1(^6S)$ transition of Mn(II), along with a band in the red range. It was found that emission spectra of the isolated products not only depend on nature of the halide, but also upon the excitation wavelength in case of X = Br.

Merzlyakova et al. (2021) prepared six crown-ether coordination compounds ZnX_2(18-crown-6), EuX_2(18-crown-6) (where X = Cl, Br, and I), MnI_2(18-crown-6), Mn_3Cl_6(18-crown-6)$_2$, Mn_3I_6(18-crown-6)$_2$, and Mn_2I_4(18-crown-6) through ionic-liquid-based synthesis. Some of these compounds exhibited outstanding photoluminescence. Excellent quantum yield was observed for Mn_3I_6(18-crown-6)$_2$ (98%). It was revealed that specific structural features of Mn_2I_4(18-crown-6) with finite sensitizer−activator couples resulted in an extremely strong emission with excellent quantum yield of 100%.

6.3 Coordination compounds of technetium

Technetium was discovered by Emilio Segrè (1937). He found that technetium was present in molybdenum exposed to high energy radiation. He could separate it.

All its isotopes are radioactive in nature and there is about 1 mg of technetium in a tonne of uranium (after nuclear fussion). The name has been derived from the Greek term "tekhnetos", which means artificial.

- It is a radioactive (silvery) metal not found naturally. Technetium-99 m (metastable) emits gamma-rays and therefore, it is used for medical diagnostic studies.
- Although technetium is an excellent corrosion inhibitor for steel, but its use is limited because it is radioactive.
- Its atomic Number is 43 and electronic configuration is [Kr] 4 d^5 $5s^2$. It belongs to group 7 and its common oxidation state is +7. Its different isotopes are ^{97}Tc (H.L. 4.2×10^6 y), ^{98}Tc (H.L. 6.6×10^6 y), and ^{99}Tc (H.L. 2.13×10^6 y)

Ikeda et al. (2012) synthesized six-coordinate distorted octahedral tetracyanidonitridorhenium(V) and -technetium(V) complexes having a volatile organic compound (VOC) coordinated at the trans position of a nitrido ligand,

$(PPh_4)_2[MN(CN)_4L]$ (where M = Re, L = MeOH, EtOH, acetone, or MeCN; and M = Tc, L = MeOH), and five-coordinate square-pyramidal tetracyanidonitrido complexes without an axial ligand, $(PPh_4)_2[MN(CN)_4]$ (where M = Re or Tc). All these complexes displayed photoluminescence at room temperature in the solid state. It was reported that there was a reversible luminescence switching between six- and five-coordinate rhenium(V) complexes. Luminescence changes were there from the five-coordinate technetium(V) complexes in MeOH vapor in the solid state, but no vapochromic luminescence was exhibited from the five- and six-coordinate complexes in an acetone vapor.

Ikeda et al. (2013) synthesized six-coordinate tetracyanidonitridorhenium(V) and -technetium(V) complexes with axial N-heteroaromatic ligands, $(PPh_4)_2[MN(CN)_4L]$ [where M = Re, L = 4-(dimethylamino)pyridine (dmap), 3,5-lutidine (lut), 4-picoline (pic), 4-phenylpyridine (ppy), pyridine (py), 3-benzoylpyridine (3bzpy), 4,4′-bipyridine (bpy), pyrazine (pz), 4-cyanopyridine (cpy), or 4-benzoylpyridine (4bzpy); where M = Tc, L = dmap, lut, pic, py, pz, or cpy]. These complexes displayed photoluminescence at room temperature in the crystalline phase. It was found that emission maximum wavelengths (λ_{em}) of the rhenium complexes with dmap, lut, pic, ppy, or py ligands were almost similar to each another with high emission quantum yield (Φ_{em}): $\lambda_{em} = 539-545$ nm, $\Phi_{em} = 0.39-0.93$, and emission lifetime (τ_{em}) = 10−45 μs at 296 K. The emissive excited state was characterized as $^3[(d_{xy})^1(d_{\pi^*})^1]$ ($d_{\pi^*} = d_{xz}, d_{yz}$). On the contrary, the emission maximum wavelength of the rhenium complex with 3bzpy, bpy, pz, cpy, or 4bzpy ligands was significantly dependent on the nature of the axial ligand in the crystalline phase: $\lambda_{em} = 564-669$ nm, $\Phi_{em} \leq 0.01-0.36$, and $\tau_{em} = 0.03-13.3$ μs at 296 K. That emissive excited state of the rhenium complex with bpy, pz, cpy, or 4bzpy ligands can be assigned to metal-to-N-heteroaromatic ligand charge-transfer (MLCT)-type emission with a spin-triplet type. It was observed that change in the excited-state characteristics of rhenium complexes by the N-heteroaromatic ligand is due to stabilization of π* orbital of the N- heteroaromatic ligand to a lower energy level than the d_{π^*} orbitals.

Chatterjee et al. (2013) investigated ligand-to-metal charge transfer (LMCT) excited state luminescence of $[Tc(dmpe)_3]^{2+}$ (where dmpe = 1,2-bis-(dimethylphosphino)ethane) in solution at room temperature and it was compared with its Re analogue. It was interesting to note that both $[M(dmpe)_3]^{2+*}$ (where M = Re, or Tc) species have very large excited-state potentials (ESPs) as oxidants, the highest among any coordination complex of a transition metal. It was revealed that this potential was available using a photon of visible light (calculated for M = Tc; $E^{\circ\prime *} = +2.48$ V vs. SCE; $\lambda_{max} = 585$ nm). It was also revealed that lowest energy transition in both the technetium and rhenium complexes were doublet−doublet process involving predominantly LMCT (dmpe-to-metal) character. Quenching was also observed for the excited states of both these rhenium and technetium

complexes due to highly oxidizing excited state potentials. Benzene and toluene both are oxidized by these Re and Tc systems.

6.4 Coordination compounds of rehenium

The element rehenium was discovered by Noddack, Tacke and Berg in (1925), it was named after the river Rhine in Europe. It is a stable metal. Its atomic number is 75 and it belongs to group 7. It exhibits a wide variety of oxidation states ranging from −1 to +7. It is used as a catalyst and it is added to high-temperature superalloys used in making jet engine parts.

Kunkely and Vogler (2000) reported that complex $Re^{VII}O_3$(oxinate) (where oxine = 8-quinolinol or 8-hydroxyquinoline) exhibited a green fluorescence at $\lambda_{max} = 511$ nm with $\varphi = 0.012$ along with a very weak red phosphorescence at $\lambda_{max} = 645$ nm. It was revealed that both these emissions originated from the lowest-energy $\pi\pi^*$ intraligand state of the oxinate ligand and heavy atom effect transmitted to the π-electron system of the ligand oxinate was very weak due to d^0 electron configuration and the higher oxidation state of rhenium.

Striplin and Crosby (2001) investigated electronic states of three complexes with the generic formula Re(I)Cl$(CO)_3$(s-phen) (where s-phen = 4,7-dimethyl-1,10-phenanthroline, 5,6-dimethyl-1,10-phenanthroline, and 3,4,7, 8-tetramethyl-1,10-phenanthroline). It was observed that methyl substitution leads to composite phosphorescence bands, which arise from ^{3}MLCT and $^3\pi\pi^*$ terms that are being separated by Franck−Condon (FC) barriers. They also defined some criteria for the occurrence of FC barriers and slow rates of radiationless transitions between terms arising from disparate electronic configurations.

Yam et al. (2003) synthesized a series of luminescent mixed-metal acetylide complexes, $[Cu_3(\mu{-}LL)_3\{\ \mu_3{-}\eta^1{-}C{\equiv}CC_6H_2R_2C{\equiv}C{-}\ p{-}Re(NN)(CO)_3\}_2]^+$ (where LL = dppm, ^{n}PrPNP; NN = bpy, ^{t}Bu$_2$bpy where R = H, Me) and $[M_3(\mu{-}LL)_3\{\ \mu_3{-}\eta^1{-}C{\equiv}CC{\equiv}C{-}Re(NN)(CO)_3\}_2]^+$ (where M = Cu, Ag and; LL = dppm, dppa; NN = bpy, Me$_2$bpy, ^{t}Bu$_2$bpy). They reported that all of them exhibited strong photoluminescence and assigned their low-energy emission as derived from states of ^{3}MLCT [d(Re)→*(NN)] character.

Zuo et al. (2003) reported that reactions of $Re(CO)_5X$ (where X = Cl, Br) with 7-amino-2,4-dimethyl-1,8-naphthyridine (H_2L^1) and 7-[2-(6-chloropyridyl)amino]-2,4-dimethyl-1,8-naphthyridine (HL^2) in the presence of t-BuOK produced η^1-naphthyridylcarbamoyl complex $[Re(CO)_4(HL^1CO)]$ and the naphthyridylamido complex $[Re(CO)_4(L^2)]$, respectively. It was revealed that first complex displayed a weak emission at 453 nm in an EtOH/MeOH (1:4, v/v) glassy solution at 77 K while second complex exhibited an intense (quantum yield: 0.22 in CH_2Cl_2) and long-lived emission (46 μs in CH_2Cl_2), (solvent-sensitive λ_{max}), in degassed solutions at room temperature.

Wenger et al. (2004) synthesized [Re(diimine)$(CO)_3$(dpe)](PF_6) (where dpe = 1,2-di(4-pyridyl)ethylene) compounds. It was reported that cis-dpe complexes exhibited yellow luminescence on UV excitation, whereas the trans-dpe counterparts are nonluminescent. It was observed that luminescence quantum yields of the cis-dpe complexes were found to be strongly dependent on diimine ligand. Trans-dpe complexes induces trans → cis dpe-ligand isomerization on irradiation (350 nm) with quantum yields (0.2), and this process also leads to on-switching of yellow luminescence. A steady state (approximately 70% cis- and 30% trans-dpe complexes) was reached after long 350-nm irradiation. On the other hand, a reverse cis → trans photoisomerization reaction was also induced on irradiating the cis-dpe complexes at 250 nm, which switches off the yellow luminescence (Fig. 6.4). The photodecomposition of the $[Re(diimine)(CO)_3(dpe)]^+$ complexes efficiently complete with photoisomerization on 250 nm excitation.

Wolcan et al. (2006) investigated photochemical properties of $\{(vpy\text{-}[Re(CO)_3(2,2'\text{-}bpy)])_m(vpy\text{-}[Re(CO)_3(phen)])_n(vpy)_p\}(CF_3SO_3)_{m+n}\}$ (where vpy = 4-vinylpyridine, m = 131, n = 131 or m = 200, n = 150, and m + n + P = 600) in solution phase. It was revealed that luminescence spectrum is similar to the emission spectrum of $\{(vpy\text{-}[Re(CO)_3(phen)])_{200}(vpy)_{400}\}(CF_3SO_3)_{200}$. The quenching of the luminescence by various quenchers was also observed and redox reactions of the MLCT excited states with the quenchers were considered responsible for quenching of luminescence. When Cu(II) and Fe(III)EDTA complexes were used as quenchers, a static quenching resulted. On the other hand, dynamic quenching was observed, where $Fe(CN)_6^{4-}$ or 2,2′,2″-triethanolamine, (TEOA) was used. They discussed photochemical and photophysical properties of the mixed-pendant polymers in terms of arrays of MLCT excited states, whose energies were determined by the diverse environments of the Re(I) chromophores. The upper-energy MLCT excited states conversions (with and without

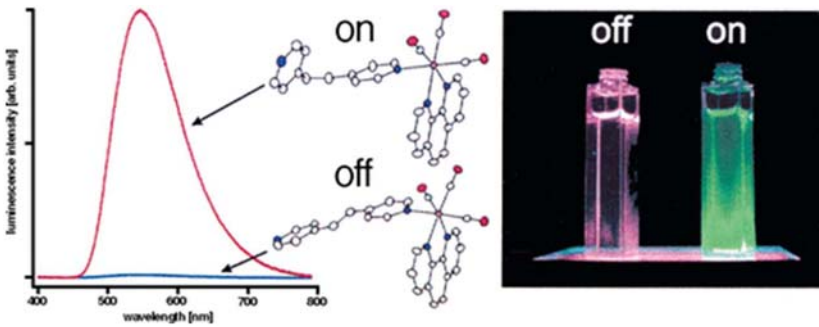

FIGURE. 6.4 Reversible cis-to trans-photoisomerization (on-off system). *Adapted from Wenger, O.S., Henling, L.M., Day, M.W., Winkler, J.R., Gray, H.B., 2004. Photoswitchable luminescence of rhenium (I) tricarbonyl diimines. Inorg. Chem. 43 (6), 2043–2048. With Permission.*

radiation) to the ground state and lower-energy MLCT excited states and excited state to the ground state could explain the experimental results.

Polo et al. (2006) reported photochemistry and photophysics of thefac-$[Re(CO)_3(NN)(L)]^+$ complexes, (where NN = polypyridyl ligands and L = stilbene-like ligands) in acetonitrile solution and in poly(methyl methacrylate) (PMMA) polymer film. These complexes diplayed trans-to-cis photoassisted isomerization of the coordinated stilbene-like ligand on irradiation. The better luminescence properties of the photoproduct, fac-$[Re(CO)_3(NN)(cis\text{-}L)]^+$ was attributed to the change of the lowest lying excited state from ^{3}IL to ^{3}MLCT. It was also revealed that emission maxima of these complexes displayed hypsochromic shifts with the increase in the medium rigidity and this change was discussed on the basis of luminescence rigidochromic effect.

Lee et al. (2007) prepared series of diarylethene-containing 1-aryl-substituted 2-(2-pyridyl)imidazole (**L**) ligands. Further reactions of 2-(2-pyridyl)imidazole ligands with $Re(CO)_5Cl$ afforded $[Re(CO)_3(\mathbf{L})Cl]$ under reflux conditions. It was also reported that open forms of the ligands showed an intense absorption band at about 320 nm corresponding to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions of the 1-aryl-2-(2-pyridyl)imidazole moiety, with mixing of $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions of the thiophene moieties. It was also revealed that rhenium(I) complexes displayed IL absorption bands around 352 nm with additional MLCT $[d\pi(Re) \rightarrow \pi^*(\mathbf{L})]$ transitions at about 425 nm. The rhenium(I) complexes exhibited three new absorption bands at 288−290, 475−480, and 712−713 nm upon excitation into either the IL or MLCT bands. This shift was attributed to the planarization of the four heterocyclic rings relative to the open forms.

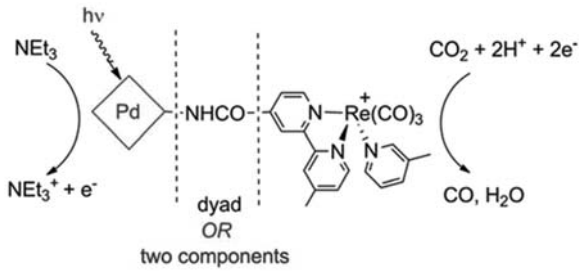
Mauro et al. (2009) prepared a series of neutral, dinuclear, luminescent rhenium(I) complexes, which can be suitable as phosphorescent organic light emitting devices (OLEDs). These compounds $[Re_2(\mu\text{-}Cl)_2(CO)_6(\mu\text{-}1,2\text{-}diazine)]$ contain diazines bearing alkyl groups either in one or both the β positions. Their electrochemical and photophysical properties were investigated. It was observed that complexes show intense green/yellow emissions in toluene solution and some of the complexes exhibited high emission quantum yields ($\varphi = 0.18-0.22$ for derivatives with disubstituted diazines) in the solid state. A strong blue shift of the emission was observed with an increase in the lifetime values. The highest-performing emitting complex, having cyclopentapyridazine ligand, was tested in a polymer-based light-emitting device with poly(9-vinylcarbazole) as matrix, and also in a device obtained by vacuum sublimation of the complex in 2,7-bis(diphenylphosphine oxide)-9-(9-phenylcarbazol-3-yl)-9-phenylfluorene (PCF) matrix.

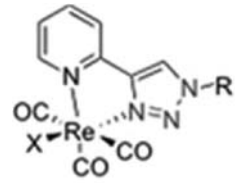
Schneider et al. (2011) investigated photochemistry and photophysics of the cationic molecular dyad, ($[Re(CO)_3(Pic)Bpy\text{-}PdTPP][PF_6]$) 5-{4-[rhenium(I)tricarbonylpicoline-4-methyl-2,2′-bipyridine-4′-carboxyamidyl] phenyl}-10,15,20-triphenylporphyrinatopalladium(II). It was reported

that a steady-state photoexcitation ($\lambda_{ex} = 520$ nm) of $[Re(CO)_3(Pic)Bpy\text{-}PdTPP][PF_6]$ in dimethylformamide (DMF) resulted in substitution of Pic by bromide at the Re(I)Bpy core. It was also revealed that when $[Re(CO)_3(Pic)Bpy\text{-}PdTPP][PF_6]$ was used as a photocatalyst for the reduction of CO_2 to CO in DMF/NEt_3 solution with $\lambda_{ex} > 420$ nm, two turnovers (TNs) CO were formed after 4 h (Fig. 6.5). In case of a two-component mixture of PdTPP sensitizer and mononuclear $[Re(CO)_3(Pic)Bpy][PF_6]$ catalyst, TNs CO were formed. It was revealed that only CO was formed after a slight induction period along with photoreduction of the sensitizer to a Pd(II) chlorin species. Palladium(II) meso-tetraphenylchlorin (a hydrogenated porphyrin analogue of PdTPP) was also synthesized and it can be substituted for PdTPP in the two-component system with $[Re(CO)_3(Pic)Bpy][PF_6]$, which gives 9 TNs for CO formation.

An overview of synthesis and properties of luminescent dinuclear tricarbonyl rhenium(I) complexes, $[Re_2(\mu\text{-}X)_2(CO)_6(\mu\text{-}1,2\text{-diazine})]$ (where X = halide, hydride, alkoxide, and thiolate) has been presented by Panigati et al. (2012). Their electrochemical and photophysical properties in solution were studied. It was reported that photoluminescent quantum yields (Φ) up to 0.53 have been obtained in fluid solution for dichloro complexes having diazines bearing alkyl groups in both the β positions. These properties, along with good processability and high stability, permitted the use of some of these complexes as a phosphorescent dopant in OLEDs.

Six Re(I) complexes$ReL^nnn(CO)_33Cl$ (n = 1−6) were synthesized by Wang et al. (2013b) using different ligands (where 2,2′:6′,2″-terpyridine ligands (**L1**), five terpyridine derivatives, namely 4′-carbazol-9-yl-2,2′:6′,2″-terpyridine (**L2**), 4′-diphenylamino-2,2′:6′,2″-terpyridine (**L3**), 4′-bis(4-tert-butylphenyl)amino-2,2′:6′,2″-terpyridine (**L4**), 4′-[naphthalen-1-yl-(phenyl) amino]-2,2′:6′,2″-terpyridine (**L5**), 4′-[naphthalen-2-yl(phenyl)amino]-2,2′:6′,





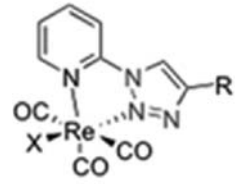


FIGURE. 6.5 The porphyrin photoreduction products during steady-state photolysis of $[Re(CO)_3(Pic)Bpy\text{-}PdTPP][PF_6]$ saturated with CO_2. *Adapted from Schneider, J., Vuong, K.Q., Calladine, J.A., Sun, X.Z., Whitwood, A.C., George, M.W., et al., 2011. Photochemistry and photophysics of a Pd (II) metalloporphyrin: Re (I) tricarbonyl bipyridine molecular dyad and its activity toward the photoreduction of CO_2 to CO. Inorg. Chem. 50 (23), 11877−11889. With Permission.*

2″-terpyridine (**L6**). It was reported that luminescence spectra of ReL2$(CO)_3$3Cl−ReL5$(CO)_3$3Cl, in CH_2Cl_2 solution at room temperature displayed strong dπ (Re) → π* (diimine) MLCT character (λ_{max} ∼ 600 nm) a small red shift relative to ReL1$(CO)_3$3Cl. It was also revealed that, the introduction of electron-donating moieties on the terpyridine unit decreases the triplet levels of the ligands at low temperature (77 K rigid matrix); thus, leading to a reduction of the energy gap between d and π* orbitals. It was found that all the complexes show an even stronger emission and a blue spectral shift (λ_{max} ∼ 550 nm) in the solid state on MLCT excitation as-compared to those obtained in solution.

Octahedral d^6 low-spin Re(I) tricarbonyl complexes are important due to their biological stability, low toxicity, long luminescence lifetimes, and large Stokes shifts. Bertrand et al. (2014) reported the bimodal IR and luminescence imaging of a Re(I) tricarbonyl complex with ligand 4-(2-pyridyl)-1,2,3-triazole (Pyta) as ligand in cells. Although Re(I) tricarbonyl complexes have certain interesting photophysical properties, which allowed for their detection in cells, but a drawback is also there like very low luminescence quantum yield in aqueous medium. They developed Re(I) tricarbonyl complexes using different ancillary ligands. It was reported that complexes with benzothiadiazole−triazole ligands displayed luminescent quantum yields in acetonitrile and can be used as luminescent metal complexes in organic media. A series of complexes was also prepared with bidentate 1-(2-quinolinyl)-1,2,3-triazole (Taquin) and 1-(2-pyridyl)-1,2,3-triazole (Tapy) ligands with different 4-substituted alkyl side chains. Their photophysical properties were also studied in acetonitrile and in mixture H_2O/DMSO (98/2). It was observed that Tapy complexes bearing long alkyl chains exhibited an enhancement of their luminescent properties relative to the parent Pyta complex. It was also revealed that MDA-displayed a strong increase in the luminescence signal in MB231 breast cancer cells incubated with the Tapy complex substituted with a C12 alkyl chain.

Re-Pyta

Re-Tapy

Adams et al. (2015) demonstrated ligand-to-metal charge transfer state (LMCT) of $[(dmpe)_3Re]^{2+}$ (where dmpe = 1,2-bis(dimethylphosphino) ethane) to be a potent oxidant ($E^0(Re^{2+}*/Re^+ = 2.61$ V vs. standard calomel electrode). This complex was earlier prepared by nontrivial routes with low yields, and in optimizing the ground state and emission energy properties of complexes of the type $[(PP)_3Re]^{2+}$ only little could be achieved through phosphine achieved modification. Improved syntheses of Re(I) tris-homoleptic diphosphine complexes $[(PP)_3Re]^+$ (where PP = 1,2-bis(dimethylphosphino)ethane (dmpe), bis(diphenylphosphino)methane (dppm), 1,2-bis(diethylphosphino)ethane (depe), bis(dimethylphosphino) methane (dmpm), $Me_2PCH_2PPh_2$, 1,3-bis(dimethylphosphino)propane (dmpp), or 1,2-bis(dimethyl-phosphino)benzene (dmpb)) was achieved by single-pot reactions making use of reducing potential of the phosphines, when treated with Re (V) oxo-complexes in 1,2-dichlorobenzene at 160−180°C. It was observed that single-electron chemical oxidation of $[(PP)_3Re]^+$ afforded luminescent Re^{II} analogs and $[(PP)_3Re]^{2+}$ complexes in good yields using Ph_3C^+, Cp_2Fe^+, or $(4\text{-}BrC_6H_4)_3N^+$ $B(C_6F_5)_4^-$ salts. It was revealed that redox and luminescence behavior of these complexes indicated that the luminescence is from a ligand P(σ)-to-metal (Re(dπ)) charge transfer (^{2}LMCT) state for all the complexes. It was also reported that structured luminescence (at 77 K) was considered due to relaxation of the ^{2}LMCT state into two spin−orbit coupled states; the ground state and a state $\sim 3000\ cm^{-1}$ above the ground state.

Lee et al. (2017) reported that most of the rhenium (I) tricarbonyl polypyridine complexes has diverse photochemical and photophysical properties through the coordination of functionalized ligands. The typical photophysical properties of the complexes (large Stokes shifts, high photostability and long emission lifetimes) allow them to act as attractive candidates for optical imaging. Isostructural relationship between rhenium and technetium-99m, rhenium(I) tricarbonyl complexes and characteristic infrared absorption bands have been studied as multimodal imaging reagents for vibrational and radioimaging. It was also revealed that facile photosensitizing properties and the three carbon monoxide (CO) ligands make rhenium(I) tricarbonyl complexes promising candidates for photodynamic therapy reagents and photoactivatable CO-releasing molecules, respectively, for treatment of cancer.

Mamud et al. (2021) synthesized a series of rhenium(I) polypyridyl compounds having photoisomerizable nitrones as ligands and investigated their photochemical and photophysical behaviors. These complexes resulted in Z → E due to the photosensitized isomerization of the coordinated ligand on irradiation and it was also confirmed. It was observed that photoisomerization quantum yields depend on the nature of the nitrone substituent, which changes the energy of the $^3IL_{Z\text{-}NitX}$ excited state (populated by photosensitization). It was also reported that ^{3}MLCT becomes the lowest-lying excited state in the E-product, which resulted in an enhancement in emission intensity. It was

suggested that such changes in spectroscopic properties of the Z or E coordinated nitrones has a potential to be used in molecular devices such as photosensors.

Chapter 7

Coordination compounds of iron, ruthenium and osmium

Liju Raju and E. Rajkumar
Department of Chemistry, Madras Christian College, Affiliated to University of Madras, Chennai, Tamil Nadu, India

7.1 Introduction

Earth-abundant transition metal complexes have gained increasing attention in the recent decade, offering the attractive potential to build sustainable large-scale molecular-based technologies in the fields of solar energy conversion, photocatalysis, and biological applications (Roundhill, 2013; Balzani et al., 1996; Kalyanasundaram et al., 1982, 1991; Lindh et al., 2020; Pashaei et al., 2016; Hagfeldt et al., 2010; Campagna et al., 2007; Xue et al., 2015; Cauwenbergh and Das, 2021; Lakowicz, 2013; Zhang and Huang, 2018; Wehlin et al., 2020; Bouché et al., 2020; Glazer, 2017; Monro et al., 2018; Li and Chen, 2020; Banerjee, 2021). Transition metal complexes, particularly Fe, Ru, and Os metal complexes have a wide range of coordination numbers, oxidation states, and geometries (Roundhill et al., 2013; Balzani et al., 1996; Kalyanasundaram et al., 1982, 1991). Coordination compounds of d^6 transition metals are being developed to provide favorable photoredox properties that rival or exceed the photophysical and photochemical properties of the existing compounds of transition metals. The fundamental understanding of the ground and the excited state dynamics of metal complexes is important for the construction of molecular architecture for their appropriate applications such as the construction of dye-sensitized solar cells, light-harvesting antennas, molecular probes, molecular machines, luminescence sensors, catalysis, and biological applications. There are several review articles and book chapters, where the photochemistry and photochemistry of Fe, Ru, and Osmium complexes are discussed (Roundhill et al., 2013; Balzani et al., 1996; Kalyanasundaram et al., 1982, 1991; Liu et al., 2016; Omar et al., 2018; Juris et al., 1988). This book chapter focuses on the recent development and different approaches adopted in fine-tuning of photophysical and photochemical properties of polypyridine and related

complexes of Fe, Ru, and Os complexes over the last decade. Few representative transition metal complexes were presented that have strong absorption in the visible region and the long-lived triplet states. Applications of these complexes are also briefly discussed in the fields of photodynamic therapy (PDT), dye-sensitized solar cells (DSSC), and photocatalysis (hydrogen generation, water oxidation, and CO_2 reduction), etc.

7.2 Coordination compounds of iron

The abundant transition metal elements all belong to the first-row transition metals, with iron being the most abundant transition metal in the Earth's crust. The coordination compounds based on iron are particularly intriguing. Since iron is a bio-essential element and its complexes are well known as candidates for photometallodrugs in cancer therapy, specifically by DNA cleavage and photocytotoxicity (Bouché et al., 2020). Further, photocatalytic reactions using iron complexes are receiving attention for the conversion and/or oxidation of organic substrates, dye-sensitized solar cells, photoelectrochemical cells and solar energy conversion. The well-documented photochemical reactions are the photo-induced decarboxylation reaction and photo-assisted Fenton reaction, both of which find their importance in the fields of environmental, materials and biological sciences (Yang et al., 2021; Lin and Lin, 2021). Unlike ruthenium and osmium complexes, the photophysics and photochemical properties of iron polypyridyl complexes and other related complexes are less explored, due to their exceptionally short (sub-picosecond) charge-transfer excited-state lifetime (Auböck and Chergui, 2015). The understanding of excited dynamics is essential for the light driven applications ranging from solar energy conversion, photoredox, photoelectrochemical, photocatalysis and chemical synthesis. The recent advances in the photophysics and photochemistry of coordination compounds of iron-polypyridyl complexes and related complexes will be discussed in the following sections.

7.2.1 Electronic structures and photophysics of iron complexes

The chemistry of iron is influenced by the range of accessible spin states, which includes low, intermediate, and high-spin iron complexes. Although iron complexes are known to exist in a variety of oxidation states ranging from 0 to +6, photoactivity has been reported mainly for the Fe^{2+} and Fe^{3+} states. The photochemistry of iron complexes is side-lined by photophysics and photochemistry of ruthenium and osmium complexes. In Fe(II)-complexes, the ligand field is much weaker than in Ru(II), this is because the distribution of the six 3d electrons in iron is closer to the nucleus than that of the 4d electrons in ruthenium (Wenger, 2019). Therefore, the metal-centered (MC) excited state ($^3T_{1g}$ and $^5T_{2g}$) falls below the triplet metal to ligand charge transfer (^{3}MLCT) state in Fe^{2+}, and three other MC states, namely ($^3T_{2g}$, $^1T_{1g}$, $^1T_{2g}$)

are energetically close. In this situation, the triplet MLCT state is deactivated within a period of ca. 50 fs, followed by vibrational relaxation on a timescale of a few ps (McCusker, 2014). The $^5T_{2g}$ state although being non-luminescent, yet it is fairly long-lived (ca. 650 ps), and this has been exploited in photochemical contexts, but it would be much more desirable to obtain a long-lived luminescent MLCT state resembling to that of Ru^{2+}. To date, this has not yet been achieved with iron. Fig. 7.1 depicts the Tanabe−Sugano diagram for the d^6 electron configuration of the simplified potential energy diagram with the key electronic states in $[Fe(bpy)_3]^{2+}$complex.

The weaker split in the ligand field (first-row transition element), which limits the photoactivity of iron complexes, causes a rapid deactivation of charge-transfer states via low-energy metal-centered states. Many attempts have been made to produce iron complexes that make them effective in light-based applications. The strategies include the following.

- Development of highly symmetric ligands field,
- Employing push-pull ligand sets,
- By creating highly strained complexes that give rise to ^{5}MLCT states
- By employing strong sigma donating N-heterocycliccarbene (NHC) ligands or by using cyclometalled ligands, which are both; σ and π donors and
- By the use of mesoionic carbenes as combined σ-donor, π - acceptor ligands.

Chelating ligands enhances the symmetry in complexes, allowing coordination of Fe^{2+} with bond angles (180 degrees between N−Fe−N) as close as possible for ideal octahedral geometry. This ensures maximum overlapping between the ligand and metal-based orbitals. This phenomenon was demonstrated by McCusker (2014) using a tridentate ligand with three pyridine binding motifs linked by carbonyl groups, resulting in a complex with an ideal octahedral geometry with a biting angle of 178.3 degrees between N−Fe−N. The inclusion of the electron-withdrawing carbonyl group aided energetically, favoring the stabilization of the lowest π* orbital of the tridentate chelating ligand. The Fe(II)-complex exhibits an excited state lifetime of 280 ps in acetonitrile at room temperature. The ligand field is so strong that the $^3T_{1g}$ state is lower than $^5T_{2g}$ state, which can lead to faster excited state decay for two main reasons.

(i) Electronic coupling between $^3T_{1g}$ and $^1A_{1g}$ is likely to be stronger than that between $^5T_{2g}$ and $^1A_{1g}$ because of the smaller change in net spin, and
(ii) Reorganization energy associated with the transition from $_3T_{1g}$ to $_1A_{1g}$ is smaller, because it involves the relaxation of a single e.g., electron to a t_{2g} orbital, while the transition from $_5T_{2g}$ to $_1A_{1g}$ involves the relaxation of two electrons from antibonding e.g., to formally non-bonding t_{2g} orbitals (Jamula et al., 2014).

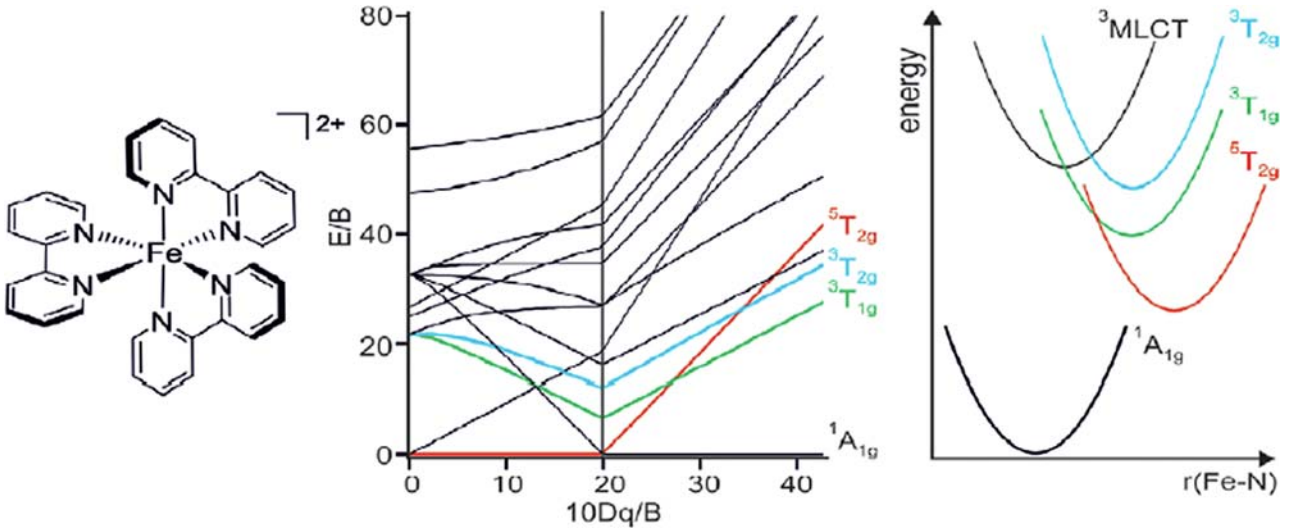

FIG. 7.1 Molecular structure of $[Fe(bpy)_3]^{2+}$; Tanabe−Sugano diagram for the d^6 electron configuration and simplified potential energy diagram with the key electronic states in $[Fe(bpy)_3]^{2+}$. *Adapted from Wenger, O.S., 2019. Is iron the new ruthenium? Chem. Eur J. 25 (24), 6043−6052. With permission.*

The push-pull ligand system developed by Mengel et al. (2015) was based on the combination of both, electron withdrawing ligand, 2,6-bis(2-carboxypyridyl)pyridine (dcpp), and electron-rich ligand *N*,*N*′-dimethyl-*N*,*N*′-dipyridine-2-yl-pyridine-2,6-diamine (ddpd) which are capable of forming tridentate chelates of the type $[Fe(dcpp)(ddpd)]^{2+}$. The push-pull combination of these ligands lowers the $^{1/3}$MLCT manifold of Fe^{2+} complexes, while at the same time raising the $^{3}T_{1g}$ and $^{5}T_{2g}$ states through increased metal-ligand orbital overlap enabled by the favorable bite angles of these two particular ligands. $[Fe(dcpp)(ddpd)]^{2+}$ exhibits a low-lying absorption band centered at 585 and 559 nm corresponding to the mixed MLCT and ligand-to-ligand charge transfer (LLCT) character (ddpd → dcpp), respectively. Interpreted this method of producing luminescence by the ligand dcpp, inducing a ligand field strength near or may be beyond the $^{5}T_{2g}/^{3}T_{1g}$ crossing point (Jamula et al., 2014). Push-pull complexes with Fe(II) have been particularly promising with ligand-to-ligand charge transfer (LLCT) states (instead of MLCT).

Another technique for improving the photophysical characteristics of Fe(II)-complexes was to access the ^{5}MLCT state via strained low spin Fe(II)-complexes. (Fatur et al., 2017; Shepard et al., 2016) were demonstrated this concept using homoleptic Fe(II)-complexes with halogenated terpyridine ((2,2′; 6′,2″-terpyridine) -tpy) ligands at the 6- and 6″-positions. The chloro and bromo substituted ligands based complexes exhibit a weaker ligand field compared to the parent complex $[Fe(tpy)]^{2+}$, due to the repulsion experienced between the tpy ligands because of the bulky halogen atoms. As a result of this repulsive interaction, the $^{5}T_{2g}$ state becomes the ground state, as expected for a weak ligand field. This strained arrangement makes it possible to excite the complex into a spin allowed $^{5}T_{2g} \rightarrow {}^{5}$MLCT transition followed by the decay from ^{5}MLCT state (or ^{7}MLCT arising due to intersystem crossing). The important observation from the $^{5/7}$MLCT lifetime of the 6,6′-halogenated-terpyridine-Fe(II)-complexes, increases from 14.0 to 16.0 and 17.4 ps along the F^{-}, Cl^{-} and Br^{-} series of complexes in acetonitrile at room temperature.

A complementary approach to enhancing the ligand field strength is to destabilize the e_g orbitals (hence, raising the ^{3}MC states' energies) with strongly σ-donating ligands such as N-heterocyclic carbenes (NHC) (Chábera et al., 2021). This strategy has resulted in an increase in ^{3}MLCT lifetime to a few tens of picoseconds in some iron(II)-complexes. This very promising approach has been well-reviewed (Lindh et al., 2020; Duchanois et al., 2018) and several different research groups have made an important contributions in recent times. Liu et al. (2013) reported a ^{3}MLCT life time of 9 ps (in acetonitrile, at room temperature (RT)) for a homoleptic complex with the tetradentate 2,6-bis(imidazole-2-ylidene)pyridine ligand, which was the longest known ^{3}MLCT lifetime for Fe(II)-complexes. The NHC ligands are known to exhibit a strong σ-donation; however, it is important to note that their π-acceptor properties are limited, that is why the pyridine unit is included to

accommodate the MLCT-excited state electron. Unfortunately, the ^{3}MLCT energy is not raised to the level of $[Fe(tpy)_2]^{2+}$complex due to its π-acceptor abilities, and this was counteracted to some extent by increasing the π-conjugation by replacing imidazolylidene by benzimidazolylidene subunits (Fig. 7.2A) offering a ^{3}MLCT life time of 16 ps as reported by Liu et al. (2016). The strong σ-donation provided by NHC ligands is possible by heteroleptic complexes maintaining a lower ^{3}MLCT (Duchanois et al., 2014). Such heteroleptic complexes of iron are as shown in Fig. 7.4.

Many research groups had envisioned the idea of using cyclometalating chelate ligands to construct photoactive iron(II)-complexes through computational studies (Tang et al., 2020). Using cyclometalating chelate ligands (Fig. 7.4), MLCT states can be stabilized owing to their π donating character, leading to a red shift in their absorption bands (Fig. 7.3D) (Dixon et al., 2015).

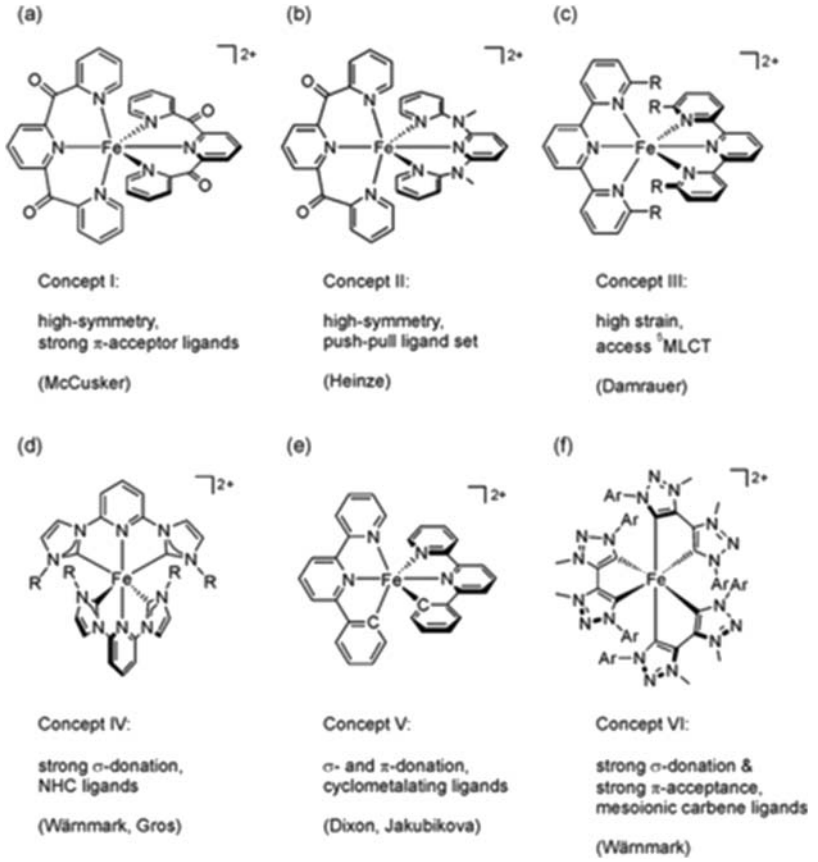

FIG. 7.2 Key strategies and concepts for obtaining Fe^{II} complexes with long-lived MLCT states, along with exemplary molecular structures. *Adapted from Wenger, O.S., 2019. Is iron the new ruthenium? Chem. Eur J. 25 (24), 6043−6052. With permission.*

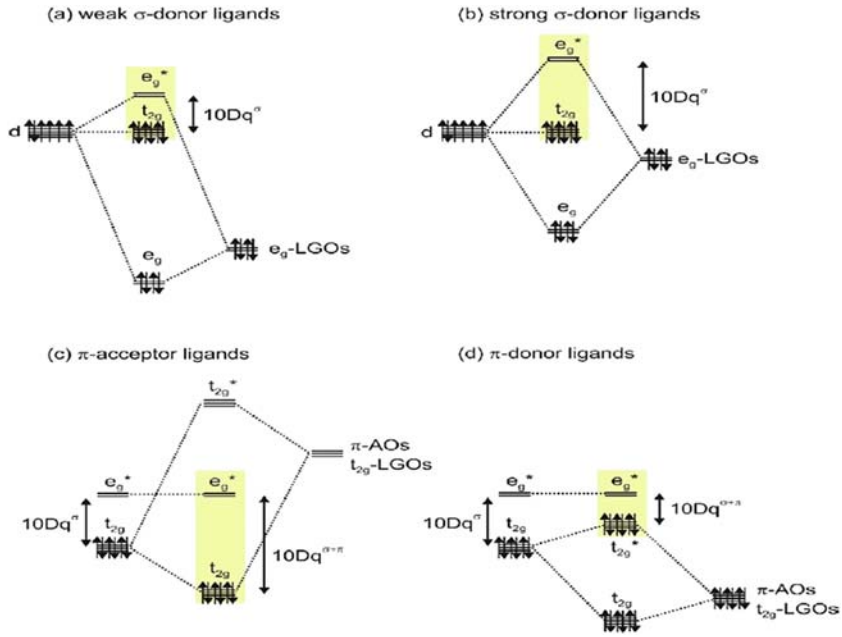

FIG. 7.3 Ligand field effects depending on the type of bonding interactions between metal d orbitals and ligand group orbitals (LGOs) or atomic orbitals (AO). *Adapted from Wenger, O.S., 2019. Is iron the new ruthenium? Chem. Eur J. 25 (24), 6043−6052. With permission.*

The ^{3}MC states are less influenced by cyclometalation, which implies that the destabilization of the e_g, orbitals by σ donation (Fig. 7.3B) is of similar magnitude to that of the destabilization of the t_{2g} orbitals by π donation. However, the ^{3}MC state is destabilized only, if the ligating carbon atoms are on one of the peripheral rings of the tridentate ligand, whereas if they are on the

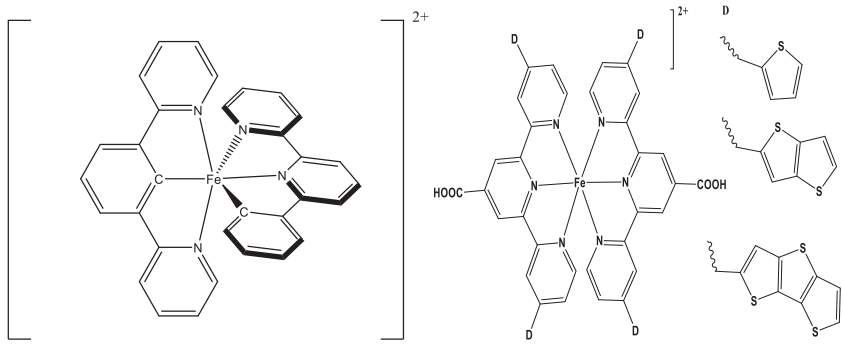

FIG. 7.4 Fe(N^C^N) (N^N^C) and complexes with π-donating ligands.

central ring, an undesirable stabilization of ^{3}MC is observed. The complexes shown in Figs. 7.2E and 7.4 are therefore identified as particularly favorable with regard to avoiding the population of the ^{3}MC state out of the ^{3}MLCT state. Depending upon the position and number of aryl groups, cyclometalation could increase the energy gap between the $^1A_1$ and ^{5}T states by the tuning of energy $\sim 8-20$ kcal mol^{-1} (Mukherjee et al., 2015). Based on all these observations, it can be predicted that cyclometalation has the potential to slow down the relaxation from the $^{1/3}$MLCT states into the ^{3}MC and ^{5}MC states. On the basis of computational studies, it is possible to identify the efficient ligands that would offer an energetically lower ^{3}MLCT compared to the ^{3}MC states. For example, a strong σ-donating acetylide based systems, in addition to the NHC chelates offered promising results (Dixon et al., 2016). Similarly, incorporation of furan thiophene, and selenophenes moieties in *tpy* unit (Fig. 7.4) greatly enhance the optical properties of the complexes (Mukherjee et al., 2017). These systems were found to have occupied π orbitals that were perfectly aligned with the t_{2g} orbitals on the iron(II), resulting in a stronger metal-ligand π interactions and an increase in the HOMO energy level. If *tpy* unit was substituted with donor groups containing extended π conjugations, for example dithienothiophene, thienothiophene, further stabilization of the ligand π orbitals can be achieved which results in a ligand-centered HOMO leading to an effect termed as HOMO inversion (Mukherjee et al., 2017).

The combined effect of having strong σ donating and π accepting ligands is another approach to tune the photophysics of Fe^{2+} complexes. Mesoionic carbene-based ligands offer this feature of being strong σ donating and π accepting character. Liu et al. (2015) developed a mesoionic carbene ligand. The heteroleptic $[Fe(btz)_2(bpy)]^{2+}$complexes displayed ^{3}MLCT lifetime of 13 ps, which was 100 times longer than $[Fe(bpy)_3]^{2+}$complexes. Fe(II)/(III) complex with mesoionic carbene ligand (btz) are presented in Fig. 7.5.

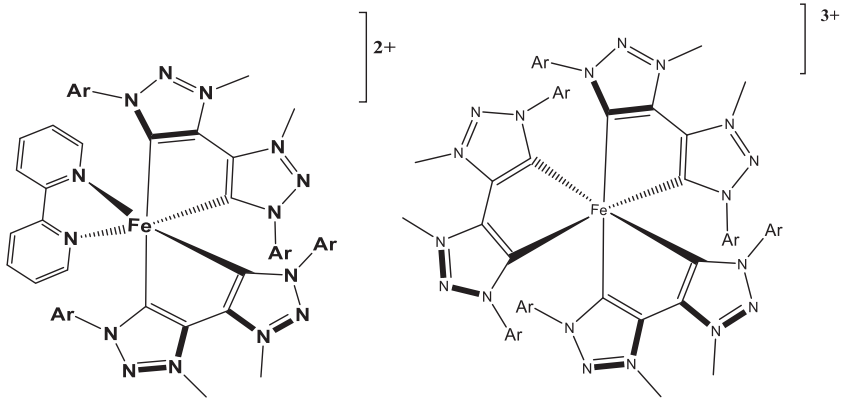

FIG. 7.5 Fe(II)/(III) complex with mesoioniccarbene ligand (btz).

The photophysical properties of the low spin d^5 Fe(III)-complex is even more spectacular than those of the Fe(II)-complexes. Chábera et al. (2017) recently reported that a low-spin Fe(III)-complex with a relatively long-lived (~100 ps) ^{2}LMCT state attained at room temperature using a strong σ-donor and π-acceptor NHC ligand. Even though the life time is short, it is promising and sufficient enough to participate in photochemical processes together with the spin allowed radiative decay to the ground state. The absorption spectra of both the oxidation states (Fe^{3+} and Fe^{2+}) feature very similar bands in the ultraviolet region, (307 nm). That are assigned to ligand-centered π-π* transitions irrespective of metal oxidation state. The visible absorption spectrum of the Fe^{3+} state features a weaker band at 384 nm (with shoulders at 400 and 420 nm), 528, and 558 nm. These low-energy absorption bands of Fe^{3+} are ascribed to LMCT transitions from the Fe(III) ground state, similar to those observed in $[Fe(CN)_6]^{3-}$ (Fig. 7.6). Excitation by any of these absorption bands resulted in readily detectable ^{2}LMCT photoemission with a quantum yield of 3×10^{-4} in CH_3CN at room temperature.

The recent advances on photoactive iron complexes can be condensed into two main strategies.

(i) Use of chelating ligands that facilitate strong metal coordination with high symmetry, as close to the ideal octahedral geometry to maximize the overlapping between metal and ligand orbitals (Darari et al., 2020), and

(ii) Use of ligands that combine strong σ-donor and π-acceptor characteristics to create strong ligand fields, in which non-radiative decay of MC states

A low-spin Fe (III) complex with 100-ps ligand-to-metal charge transfer photoluminescence. Nature 543 (7647), 695–699. With permission.*

are shifted to high energies. Fe(III)-systems have also gained attraction in inorganic photophysics. The photophysical and photochemical properties of recently reported Fe^{3+}complex with an anionic scorpionate tris(NHC) ligand are very similar to that of the prototype ruthenium(II)tris-bipyridine complex in several aspects, and they appear to be even better in terms of photostability (Kjaer et al., 2019). Furthermore, heteroleptic Fe(III)-complexes could be interesting systems for fine tuning of HOMO and LUMO energies.

7.2.2 Photochemistry of iron complexes

Iron complexes are known to exhibit a wide range of photo-induced reactions, which include photo-induced electron/energy transfers, photo-induced ligand degradation, photo-induced cleavage of bonds, photo-induced release of small molecules, and photocatalysis reactions, etc. There are several articles available in the literature based on iron photochemistry, and hence, we have discussed representative examples on a few photochemical processes involving iron complexes (Lindh et al., 2020; Chen and Browne, 2018).

The earliest report on the photochemistry of iron complexes was in Fenton type reactions. The Fenton reagent is a combination of $H_2O_2/Fe^{3+/2+}$, which is typically used as a by-product to generate reactive oxygen species (ROS) with water. This is used in waste water treatment and antimicrobial treatment processes (Gonçalves et al., 2020; Costa et al., 2020). The production of ROS is initiated under irradiation (($\lambda > 580$ nm) by the rapid generation of $Fe^{3+/2+}$ through photoreduction of the Fenton reagent. The photoreduction of Fe(II) ion by hydrogen peroxide to Fe(III) ion can occur in the radiation range of 280−550 nm. A general mechanism can be depicted as:

$$Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + HO^{\bullet} + OH^{-} \quad (7.1)$$

$$Fe^{3+} + H_2O_2 \rightarrow Fe^{2+} + HOO^{\bullet} + H^{+} \quad (7.2)$$

$$Fe(OH)^{2+}\ h\nu \rightarrow Fe^{2+} + HO^{\bullet} \quad (7.3)$$

The drawback of this type of Fenton reaction is the need to maintain an acidic pH that helps in generating photoactive Fe-complexes and to avoid the formation of Fe(OH) precipitates (Zhang and Zhou, 2019). Thus, carboxylate ligands based Fe-complexes were investigated to achieve (Zhang et al., 2019; Vilar et al., 2017).

(i) Formation of strong and steady complexes between iron in an aqueous medium,

(ii) Formation of more photo-active species with the largest production of $^{\bullet}OH$ radicals, thereby resulting in a higher quantum efficiency compared to the conventional photo-Fenton reactions, and

(iii) Reactions that can occur at near-neutral pH (Lumbaque et al., 2019). Seibert et al. (2017) reported the use of Fe(III)-carboxylate complexes for photo-Fenton type degradation of landfill leachate.

The best results were obtained with the photo-reactor operating at pH of 6.0, 100 mg Fe(III) per liter of EDTA (Ethylenediamine tetraacetic acid); consuming 275 mM H_2O_2 and demanding about 8 kJ_{UV} L^{-1}, resulting in total discoloration and 80% reduction of the landfill leachates. Solar Fenton reaction, which employ siron(III)-ethylendiamine-N′,N′-disuccinic acid (EDDS) for inactivation of pathogen in ground water was reported by García-Fernández et al. (2019). A suitable candidate for the development of iron chelated soluble complexes, ethylendiamine-N′,N′-disuccinate acid (EDDS) is environmentally acceptable, biodegradable and operates closely to neutral pH.

Reduction of water and CO_2 can be affected photocatalytically by iron complexes. Though ruthenium and osmium complexes have displayed outstanding performance as photosensitizers, many iron complexes are seen to be reported to act as photosensitizers. Iron polypyridyl complexes exhibit a very strong absorption in the visible-light region but suffer from very rapid deactivation of the photocatalytically active $^{1/3}$MLCT states into inactive MC states. This behavior is different for the other members of the iron family as they have a large energy gap between the $^{1/3}$MLCT and MC states sufficient enough to have a longer lifetime (Liu et al., 2016). However, the photophysical properties of iron complexes can be finely-tuned by their coordinating ligands, based on various concepts explained in earlier sections; thereby, increasing their applicability in photochemical processes. One such effective technique to achieve the expected photophysical properties of Fe-complexes is to use N-heterocyclic carbene ligand (NHC) with the polypyridyl system. Iron-NHC complexes are envisioned to exhibit potential photochemical properties from the intensive physicochemical and computational analyses (Harlang et al., 2015). Bauer et al. (2017), Zimmer et al. (2017) reported (NHC) complexes of iron as photosensitizers for the photo-induced water reduction (Fig. 7.7). They first demonstrated that Fe^{2+}—NHC complexes can be used as noble metal-free transition-metal complex as photosensitizer for a light-driven water reduction process.

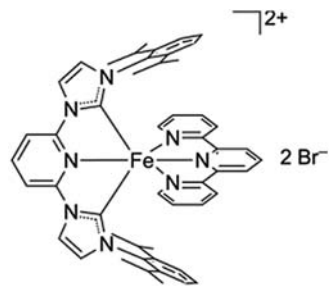

FIG. 7.7 Fe:NHC complex, photosensitizer for water reduction. *Adapted from Bauer et al., 2017, Eur. J. Inorg. Chem. 2017 (11), 1504—1509. With permission.*

The combined effect of both; tpy and NHC ligand in heteroleptic Fe(II) complexes would offer optimized photochemical properties for photocatalytic proton reduction (Zimmer et al., 2018). The tpy would help to have intense absorption in the visible region and bis-NHC ligand stabilizes the photoactive MLCT states and ensures photostability of the complexes (Duchanois et al., 2014). The resulting complex offered the advantages of high stability and low price compared to conventional Ru/Os/Ir-based photosensitizers. Iron-based coordination compounds have recently been employed as photosensitizers for reducing CO_2 (Rao et al., 2018). A simple terpyridineiron(III)-complex was used as an organic thermally activated delayed fluorescence (TADF) photosensitizers for carbon dioxide reduction (Wang et al., 2020).

A significant enhancement of CO production with 99.3% selectivity in the presence of water was observed. The turn over number (TON) was determined to be 2250 and turn over frequency (TOF) was 60 min^{-1}. The proposed mechanism of the photo catalytic reaction is shown in Fig. 7.8.

Because of their capacity to penetrate deeper tissue, metal complexes that can be triggered by red light (biological window) are extremely important as phototherapeutic sensitizers (Tang et al., 2020). Iron based complexes have also proved to be efficient photosensitizer in photodynamic therapy and used

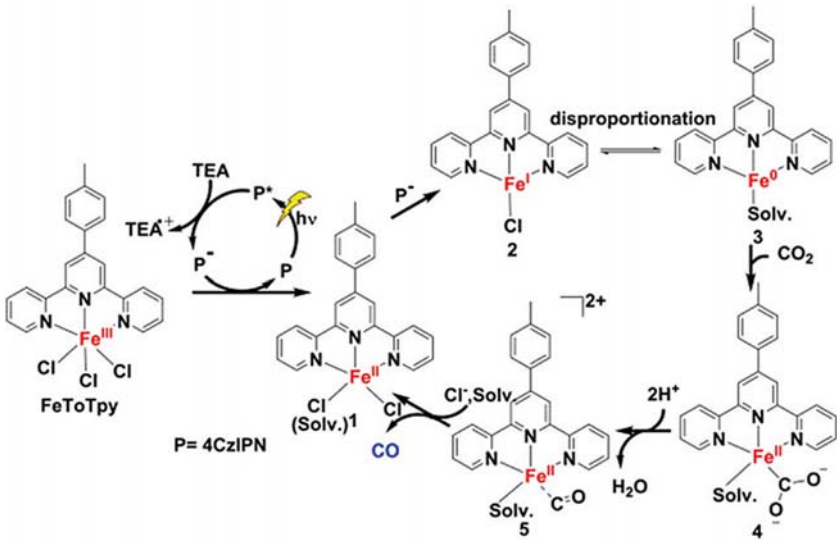

FIG. 7.8 Proposed mechanism for photocatalytic CO_2 reduction. *Adapted from Wang, Y., Gao, X.W., Li, J., Chao, D., 2020. Merging an organic TADF photosensitizer and a simple terpyridine−Fe (III) complex for photocatalytic CO_2 reduction. Chem. Commun. 56 (81), 12170−12173. With permission.*

as photochemotherapeutic agents (Tabrizi, 2018; Karges et al., 2019; Karges and Gasser, 2020; Sahoo et al., 2021). Sahoo et al. (2021) reported a Fe(III)-curcumin complexes appended with biotin for targeted PDT. The visible light triggered cytotoxicity was studied in HeLa, HepG2 and MCF-7 cell lines. The photodynamic effect was observed between 400 and 700 nm excitation. The complexes displayed their ability to act as targeted photochemotherapeutic drugs.

As an alternative for other transition metals in sustainability, eco-friendly as well as industrial uses, the fundamental photophysical, photochemical and applications of iron-based coordination compounds are increasing rapidly. However, in order to employ iron as a PS effectively, one must fine tune its photophysical features such as long-lived excited state, red light absorption by carefully selecting their ligand system, which can be useable for efficient PS for light driven applications.

7.3 Coordination compounds of ruthenium

Ruthenium(II)-complexes are of great interest for researchers due to their rich photochemistry and photophysical properties. Ruthenium complexes are extensively used for the construction of dye- sensitized solar cells, light harvesting antennas, molecular probes, molecular machines, luminescence sensors, catalysis and biological applications (Roundhill, 2013; Balzani et al., 1996; Kalyanasundaram, 1982, 1991; Lindh et al., 2020; Campagna et al., 2007). This interest is due to unique photophysical properties such as luminescence at RT, long excited state life time, moderate quantum yield, spectroscopically distinctive redox states, ability to undergo electron and energy transfer processes and fine tuning of electronic properties and chemical stability. Here, a recent development and different approaches adopted in fine tuning the photophysical and photochemical properties of Ru(II)-complexes over the last decade have been discussed.

7.3.1 Photophysics of $[Ru(NN)_3]^{2+}$ complexes

The photophysical and photochemical properties of $[Ru(NN)_3]^{2+}$ (NN- polypyridine ligands) complexes can be tailored to a greater extent by introducing electron-donating and electron-withdrawing groups into the 2,2′-bipyridine (bpy), 1,10-phenanthroline (phen) and additional nitrogen atoms into the pyridine ring; thus, it offers greater tenability (Ashford et al., 2014). Furthermore, the extensive synthetic chemistry available allows for systematic modification of their photophysical properties, and the addition of anchoring groups that allow immobilisation on a variety of surfaces, including semiconductors, polymers, and other materials, leads to a diverse set of applications (Roundhill, 2013; Balzani et al., 1996; Kalyanasundaram, 1982, 1991; Juris et al., 1988).

7.3.1.1 Absorption spectra of $[Ru(NN)_3]^{2+}$ complexes

The d^6, Ru(II) system and the polypyridyl ligands forms six coordination "Oh" geometry, where the ligands possess σ donor orbitals localized on the nitrogen atoms and π donor and π^* acceptor orbitals essentially delocalized on aromatic rings. $[Ru(bpy)_3]^{2+}$ and its analogs complexes have an octahedral geometry of D_3 symmetry. A simplified molecular orbital diagram along with the absorption spectrum of $[Ru(bpy)_3]^{2+}$ is shown in Fig. 7.9.

The different types of transitions between molecular orbitals in the complex correspond to several absorption bands in the visible region absorption spectrum of the complex. The observation of absorption bands in the visible region is due to the photoexcitation of $[Ru(NN)_3]^{2+}$. These bands are usually assigned to metal-to-ligand-charge-transfer (MLCT) transitions, in which an electron is promoted from a Ru-based molecular orbital (π_M), belonging to the filled metal t_{2g} shell, to the empty π^* orbitals of the bipyridine ligands (π^*_L) (Frank-Condon singlet metal-to-ligand charge transfer ^{1}MLCT state) and localization of the electron on one of the bipyridine ligands, while promotion of an electron from π_M to σ^*_M orbitals leads to metal-centered (MC) excited states. The ligand-centered (LC) excited states can be obtained by promoting an electron from the π_L ligand orbital to π^*_L ligand orbital.

Modern inorganic photochemistry focuses on the interplay of metal-to-ligand charge transfer (MLCT) and metal-centered (MC) excited state of

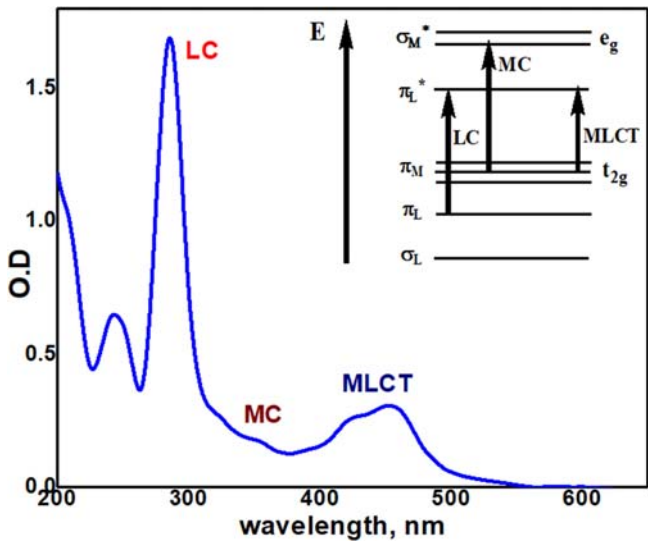

FIG. 7.9 Absorption spectrum of $[Ru(bpy)_3]^{2+}$ in acetonitrile (Inset shows the molecular orbital diagram). *Adapted from Feng, L., Wang, Y., 2018. A key factor dominating the competition between photolysis and photoracemization of* $[Ru(bpy)_3]^{2+}$ *and* $[Ru(phen)_3]^{2+}$ *complexes. Inorg. Chem. 57 (15), 8994−9001. With permission.*

Ru(II)-complexes and their derivatives. Both of these two states play important role in the photophysical properties such as photoluminescence, photoinduced electron and energy transfer processes and photochemical properties such as photo-isomerization, and photo-release properties of these metal complexes for their applications in the fields of solar energy conversion, photocatalysis, sensor, imaging and photodynamic therapy etc (Feng and Wang, 2018; Soupart et al., 2020; Brabec and Kasparkova, 2018). The multiple deactivation pathway of $*[Ru(NN)_3]^{2+}$ are depicted in Fig. 7.10. According to picosecond time resolved spectral studies, the MLCT states become essentially localized onto one ligand extremely rapidly, even when the ligands are identical, as in $[Ru(bpy)_3]^{2+}$. Dongare et al. (2017) comprehend various experimental techniques to analyze the electronic structure of the excited MLCT state and whether the excited state ($dp^5\pi^{*1}$) may be localised on one ligand $[Ru^{III}(bpy)_2(bpy^{-\bullet})]^{2+*}$or delocalized over all three ligand $[Ru^{III}(bpy^{-\bullet 1/3})_3]^{2+*}$. The derived electronic structural model originated from various time scale spectroscopic techniques from initial light absorption by $[Ru(bpy)_3]^{2+}$ and related MLCT excited state to final excited state equilibration, and the given sequence is GS → ^{1}MLCT → ^{3}MLCT → Vibrational relaxation → Solvent relaxation.

In less than 300 fs, ^{1}MLCT state undergoes rapid intersystem crossing (ISC) to a long-lived triplet excited state (^{3}MLCT) (Damrauer et al., 1997; Cannizzo et al., 2006; Wallin et al., 2005; Dietzek et al., 2006; Alary et al., 2007; Henry et al., 2008; Harriman and Izzet, 2007; and Kim et al., 2020). Dietzek et al. (2006) established that the two distinctive time scales have been discovered by using femtosecond four-wave mixing of the relaxation processes leading to a thermalized ^{3}MLCT state in the complex, $[Ru(tbbpy)_3]^{2+}$ (tbbpy = 4,4′-di-*tert*-butyl-2,2′-bipyridine). An ultrafast process, which is attributed to intersystem crossing, takes place within 200 fs by rapidly depopulating the initially photoexcited ^{1}MLCT state, followed by a second process on a picosecond time scale, assigned to vibrational cooling within the

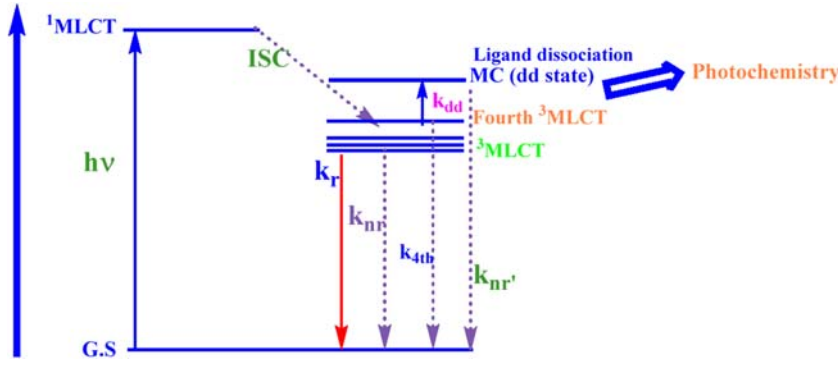

FIG. 7.10 Various deactivation pathways of $*[Ru(NN)_3]^{2+}$.

^{3}MLCT state. Henry et al. (2008) investigated the early picosecond time scale of excited state dynamics of $[Ru(NN)_3]^{2+}$ complexes by picosecond Kerr-gated time resolved resonance Raman (ps-TR^3) spectroscopy. From these results, the observation that the thermally equilibrated excited (THEXI) state is not fully evolved on the femtosecond timescale, as previously suggested, but the changes in the vibrational spectra are seen up to some 10 ps. The ^{3}MLCT state comprises manifold of four MLCT states that spans a narrow energy range. The three lowest-energy triplet states can be separated only at low temperature, the energy spacing being less than 200 cm^{-1}, and they can be approximated to a single entity at RT (Horvath and Gordon, 2010; Chang et al., 2012; Zigler et al., 2016). The fourth ^{3}MLCT state lies $\sim$400−1000 cm^{-1} above this ensemble and its existence is indicated from a variety of kinetic, emission polarization and temperature dependent emission studies (Wallin et al., 2005; Bhasikuttan et al., 2002; Shaw et al., 2004; Myrick et al., 1987; Ito and Meyer, 2012). Molecular orbital calculations led to the conclusion that the fourth MLCT state possesses more singlet character than the low energy triplet, and temperature dependent studies confirmed that this species decays faster than the ensemble.

The direct observation of the vibrational band at 1599 cm^{-1} in time resolved infrared spectroscopy under photoexcitation of $[Ru(bpy)_3]^{2+}$complex at different experimental conditions confirms the observation of a short-term population of ^{3}MC state ($\sim$23 ps) during the relaxation to the bottom of the ^{3}MLCT state (Mukuta et al., 2016; Sun et al., 2013). The localization of the electron on one bpy ligand changes the ground state D_3 symmetry to a C_2 symmetry in the ^{3}MLCT state. The interplay between electronic and geometric changes is of prime importance in elementary charge-transfer processes. Static and time-resolved resonance Raman studies have been carried out on $[Ru(bpy)_3]^{2+}$ to measure the structural changes in the ^{3}MLCT state, but these were mainly concentrated on the bond changes within bpy^- ligand. Bressler and Chergui (2004) and Gawelda et al. (2006) reported the picosecond time resolved XANES (X-ray Near-Edge Absoption Structure) and EXAFS (Extended X-ray Absorption Fine Structure) study of both; ground and excited state $[Ru(bpy)_3]^{2+}$ complexes in aqueous medium is attempted. From these studies, a Ru−N bond contraction by $\sim$0.03Å in the excited state compared to the ground state has been proposed. This weak bond contraction is due to dominant electrostatic and polarization interaction between the oxidized Ru atom and the neutral & reduced bpy ligands and by steric effects due to straining of the latter.

Because of the spin forbidden ($T_1 \rightarrow S_0$) transition, ^{3}MLCT excited state is long lived and commonly used for photoinduced electron or energy transfer processes. The molar absorption coefficient of the complex depends on the overlapping of HOMO and LUMO molecular orbitals and its usually partially allowed ($S_0 \rightarrow {}^1$MLCT) transition. The partially allowed transitions that determine the molar absorptivity of the complexes, where there is a partial

overlapping of HOMO and LUMO molecular orbitals. The intersystem crossings (ISC) ($S_1 \rightarrow T_1$) and ($T_1 \rightarrow S_0$) is dramatically enhanced by the process called spin orbit coupling (SOC), which is induced by the heavy atom effect. When there is a greater spin orbit coupling, the T_1 state has a shorter life time. In addition, the photoexcited state have a stronger redox property than its ground state, which is useful for constructing photocatalysts, where electron relay plays a key role (Kim et al., 2020).

7.3.1.2 Emission properties

The emission of ^{3}MLCT ($*[Ru(bpy)_3]^{2+}$) state exhibited a measured life time of about 900 ns in acetonitrile. This is long enough for the excited state to efficiently transfer its energy to another molecule (quencher) either by energy or electron transfer. In the absence of a quencher, the excited state undergoes deactivation through both non-radiative and radiative decay pathways with an emission quantum yield of 0.062 (in acetonitrile). $[Ru(NN)_3]^{2+}$ complexes are highly luminescent and the λ_{max}^{em} is in the range of 600−700 nm. The excitation of any one of its absorption bands, it emits a single emission band with maximum wavelength at 602 nm (in H_2O). The emission properties of ruthenium(II)-polypyridyl complexes can provide much information about the lowest excited state (Lakowicz, 2013). It exhibits a fairly long lived emission with moderate intensity in degassed aqueous solutions ($\tau = 0.6$ μs; $\Phi = 0.042$). With a quantum yield of 0.4 and life time of 5 μs at 77 K, the emission spectrum of $[Ru(NN)_3]^{2+}$ complex exhibits some vibrational structure.

The highest energy peak in the steady state emission spectrum at 77 K can be used to estimate the excited state energy. The excited state energy is depends on the electron donating and accepting substituents on the ligands and the delocalization effect in the ligands. The excited state energy can be tuned by the appropriate choice of the substituents. Emission properties of Ru(II)-complexes, such as intensity, life time, quantum yield and energy position are strongly influenced by the medium (Roundhill, 2013; Balzani et al., 1996; Kalyanasundaram, 1982, 1991; Mareeswaran et al., 2014; Rajkumar et al., 2014; Sangiliapillai et al., 2016; Swarnalatha et al., 2011). The introduction of electron withdrawing groups lowers the ^{3}MLCT level; thereby, shifts the emission maximum to the longer wavelength region.

7.3.1.3 Excited state life time

The photoexcited molecule, the time allowed for a reaction to occur is of the order of the lifetime of the particular excited state or less, when the reaction step must compete with other photophysical processes. The excited state lifetime (τ_r) of a molecule is related to the rate of radiative and nonradiative processes, through Eq. (7.4).

$$1 / \tau_r = k_r + k_{nr} + k_{4th} \exp(-\Delta G_{4th} / k_B T) + k_{dd} \exp(-\Delta G_{dd} / k_B T) \quad (7.4)$$

where k_r and k_{nr} are the radiative and nonradiative rate constants for the deactivation of ^{3}MLCT state and k_{4th} and k_{dd} represent the sum of radiative and nonradiative decay rate constants for the depopulation of the corresponding state. According to the energy gap law, the nonradiative decay rate constant, k_{nr}, is influenced by the energy gap between the ground state and the ^{3}MLCT state. The rate of non-radiative decay increases as the energy difference between the ground state and the ^{3}MLCT state decreases, and the life time of the excited state decreases. The excited state lifetime values of $[Ru(NN)_3]^{2+}$ are highly sensitive to the nature of the substituents in the 2,2′-bipyridine and 1,10-pheanthroline ligands and solvent system used. The influence of the nature of the ligand and medium on the τ values can be explained in terms of energy level diagram shown in Fig. 7.2.

7.3.1.4 Quantum yield

The emission quantum yield (Φ) measures the efficiency by which the absorption of photon leads to the production of excited state molecules. The emission quantum yield is related to the rate of radiative (k_r) and nonradiative (k_{nr}) decays of excited states through Eq. (7.5).

$$\Phi_{em} = k_r \tau = k_r / (k_r + k_{nr} + k_{4th} + k_{dd}) \quad (7.5)$$

In Eq. (7.5), τ is the excited state life time of $[Ru(NN)_3]^{2+}$. The quantum yield of $[Ru(bpy)_3]^{2+}$ is 0.062 in acetonitrile. According to the energy gap law, the rate of nonradiative decay is related to the emission energy by Eq. (7.6).

$$k_{nr} \; \alpha \; e^{-CE_{em}} \quad (7.6)$$

where E_{em} is the energy in cm^{-1} at the maximum wavelength. Nonradiative deactivation of excited states takes place via two routes. One is from the lowest excited state (^{3}MLCT), which decays to the ground state directly. The other is via the high-lying ligand field (^{3}LF) state, which undergoes fast nonradiative decay to the ground state or ligand dissociation. This fast nonradiative decay is responsible for the low quantum yield. It also depends on the intersystem crossing of ^{3}MLCT state to the ^{3}LF state. The quantum yield and life time was found to decrease with increase in temperature (Hagfeldt et al., 2010).

7.3.1.5 Excited state redox properties

All molecular excited states are potential redox reagents since the absorption of light leads to excitation of electron to a high energy level, where it is more weakly bound and at the same time, an electron hole in the low energy level. Hence, excited state species can be a better oxidant as well as a better reductant than the corresponding ground state and it is represented in Eq. (7.7).

$$[Ru^{II}(bpy)_3]^{2+} \rightarrow [Ru^{III}(bpy)_2(bpy)^-]^{2+} \quad (7.7)$$

The excited state redox potentials are obtained from the redox potentials of the corresponding ground state and the spectroscopic excited state energy. The excited state redox potentials are given to a first approximation by the following Eqs. (7.8) and (7.9).

$$E^{+}_{(D/*D)} = E^{+}_{(D/D)} - E_{0\text{-}0} \tag{7.8}$$

$$E_{(*A/A-)} = E^{-}_{(A/A)} + E_{0\text{-}0} \tag{7.9}$$

Here $E_{(D+/D)}$ and $E_{(A/A-)}$ are the ground state and $E_{(D+/*D)}$ and $E_{(*A/A-)}$ are the excited state oxidation and reduction potentials of $[Ru(NN)_3]^{2+}$, respectively and $E_{0\text{-}0}$ is the zero, zero excitation energy of the complex. Oxidation of $[Ru(NN)_3]^{2+}$ complexes usually involves the removal of the electron from a metal orbital ($d\pi_M$) and reduction involves addition of electron to the ligand.

The oxidation potential is affected by the nature of the ligands because the amount of electric charge localized on the metal (the tendency to lose an electron) is governed by σ and π donor properties of the ligands. For the ligands of same series, the presence of electron withdrawing groups increases the oxidation potential while the opposite occurs for electron donating substituents. Reduction usually takes place on the ligand. So the ground state reduction potential of $[Ru(NN)_3]^{2+}$ will be related to the reduction potential of the free ligand. However, the ability of a coordinated ligand to accept an electron also depends on the amount of charge transferred to the metal or received from the metal via σ and π bonding by the other ligands. In addition, the changes in the reduction potential of the ground state do not cause an equal change in the reduction potential of the excited state because the energy of the MLCT level decreases as the ligand becomes easier to be reduced. So the main factor, which governs the excited state redox potentials of $[Ru(NN)_3]^{2+}$, is the change in the structure of the ligands. In mixed ligand complexes, the electron is located on the ligand with the larger reduction potential value.

7.3.1.6 Photophysical properties of Ru(II)-complexes

The research interest focuses on to achieve lower energy absorption with a significant emission and a long-lived excited state. One strategy to achieve this is to reduce the HOMO-LUMO energy gap, which would result in a red shift in the absorption and emission signature of the complexes. Though this strategy may not alter the molar extinction coefficient significantly, (Cerfontaine et al., 2020) demonstrated that trinuclear Ru(II)-polypyridyl complexes with tritopicbridging ligands connecting between 4,4′ and 5,5′ positions of the bipyridine moiety between para and meta position of the central as well as peripheral bipyridine moieties (Fig. 7.11), exhibiting lower energy π^* acceptor orbitals that induces a red shift of MLCT absorption bands and photoluminescence. The absorption and normalized steady state emission spectra are shown in Fig. 7.11. In addition to the expected peaks, a broadening of

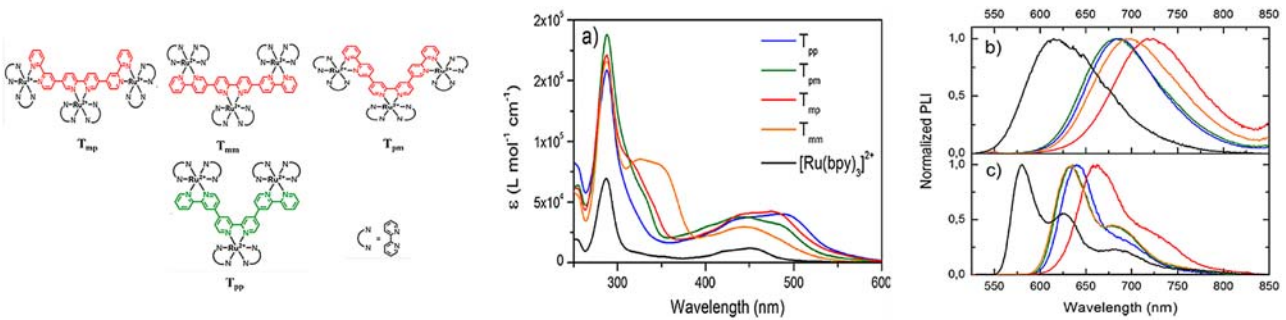

FIG. 7.11 The ortho/para/meta substituted bypyridine group on to the bipyridine core at their 4,4′ and 5,5′ positions and the trinuclear Ru(II) complexes and UV−visible absorption spectra for the complexes in acetonitrile at 293 K (A). Normalized steady-state photoluminescence spectra of the complexes in acetonitrile solution at 293 K; (B) and in butyronitrile rigid matrix at 77 K and (C). *Adapted from Cerfontaine, S., Troian-Gautier, L., Duez, Q., Cornil, J.R.M., Gerbaux, P., Elias, B., 2020. MLCT excited-state behavior of trinuclear ruthenium (II) 2, 2′-bipyridine complexes. Inorg. Chem. 60 (1), 366−379. With permission.*

ligand-centered transition around 290 nm was observed and became more prominent as the number of linearly arranged bipyridine moieties increased ($T_{mm} > T_{mp} > T_{pm} > T_{pp}$). Complex, T_{mm} exhibited an additional peak around 336 nm and having low energy peak at 445 nm, whereas other studied complexes exhibited two peaks around 450 and 480 nm. All these transitions are assigned to ^{1}MLCT transitions and have high molar absorption coefficients than parent complex, $[Ru(bpy)_3]^{2+}$. The spectral correlation was further supported by cyclic voltammetry.

At both 77 and 293 K, the emission spectrum of all the four complexes exhibits a strong photoluminescence (PL) peak with single exponential life time. Though there are two types of metal centers, i.e., peripheral and central Ru(II), the single exponential life time indicated that the photoemission originated from only one type of Ru(II), this was due to the energy transfer associated between the two types of metal ceneters. The bathochromic shift in the PL suggests that the energy transfer is taking place from the peripheral metal centers to the core metal center. At 77 K, the corresponding photoluminescence life times and quantum yields followed in the order $T_{pp} > T_{pm} > T_{mm} > T_{mp}$. These complexes exhibit a decrease in life time and quantum yield with increase in temperature. An increase in the molecular hierarchy is one way of tuning the photophysics of Ru(II)-polypyridyl complexes, such as polymetallic and other supramolecular architectures. Metallodendrimers are one of the categories. It could be one of three types: Metal core, metal at the periphery, or metal as connectors on a dendrimeric ligand (Vögtle et al., 1999; Vonlanthen et al., 2016). Ru(II)-based polynuclear complexes, dendrimers and hetero-metallic complexes, etc have been developed and their photophysical properties have been explored (Mishra et al., 2013; El-Batal et al., 2013; Anandkumar et al., 2017; Zhang et al., 2020).

The substitution on the ancillary unit on the polypyridyl core has strong influence on the photophysical properties of Ru(II)-complexes. In a study conducted by Shalan et al. (2017), correlating the effect of *para* substitutionson ruthenium(II)-polypyridine complex to their photophysical properties was investigated. A series of ruthenium(II)-complexes, containing electron donating and withdrawing groups of the type $[Ru(4,4'\text{-}X_2bpy)_2(phenA)]^{2+}$, (where X (*para* substituted) = Cl, H, *t*-Bu, Me OPhe, OMe, or NMe_2, bpy = 2,2′-bipyridine, and phenA = 5-acetamido-1,10-phenanthroline) were prepared and their photophysical properties were also investigated. Further, these complexes were evaluated for their photocatalytic activity. The quantum yield and life time of the complexes containing electron withdrawing group on the 4,4′-disubstituted-2,2′-bipyridine ligand have higher values than the electron donating NMe_2 group. In addition, the photocatalytic activity of the complexes exhibited a three fold enhancement in initial reaction rate, when substituent was changed from Cl to *t*-Bu. However, the reaction rates of the catalytic system decrease thereafter with the more electron donating groups introduced in the ligand, which suggests that it followed

different reaction pathway. Furthermore, the introduction of anionic donors, like carbanionic or N-containing aromatic units, into ruthenium(II) coordination sphere is another proven strategy to increase the HOMO level in the system. This method was successfully demonstrated by O'regan and Gratzel (1991) on highly efficient dye- sensitized solar cells (DSSC).

In recent years, Ru(II)-complexes incorporating boron have been reported. Because of the presence of vacant p-orbital on the boron atom in the triarylborane molecule, it exhibits synergetic interactions between MLCT of a transition metal complex and intramolecular CT interaction between π orbitals of the aryl group. Nakagawa et al. (2015, 2017) developed a series of Ru(II)-complexes bearing (dimesityl)borylduryletheynyl (DBDE) moiety in the 4,4′- and 5,5′position of the 2,2′-bipyridine and 1,10-phenathaline ligands (Fig. 7.12). The molar extinction coefficient at $\lambda_{abs}{}^{max}$ of the complex increases with increasing n value i.e., number of DBDE groups in the periphery units. Furthermore, the complex ($n = 3$) exhibited an intense absorption ($\varepsilon_{MLCT} = 5.6 \times 10^4\ M^{-1}\ cm^{-1}$) at 488 nm for $n = 3$ and emission quantum yield of 0.43, which was very high compared to the other Ru(II)-analogs. It was attributed that S_1-T_1 splitting of energy ($\Delta E_{ST} = E_{abs} - E_{em}$) and the mixing of excited singlet-triplet state favors larger radiative transition (k_r).

A long lived temperature dependent emission from Ru(II) system having and arylboron unit was demonstrated. The tris(1,10-phenanthroline)ruthenium(II) complexes $[Ru(phen)_3]^{2+}$ bearing a (dimesityl)borylduryletheynyl (DBDE) charge-transfer (CT) unit at the four or five position of one of the three phenanthroline core as shown in Fig. 7.13 (Sakuda et al., 2011).

In comparison to $[Ru(phen)_3]^{2+}$complex ($\tau = 0.42\ \mu s$), Ru(II)-complexes bearing a (dimesityl)borylduryletheynyl (DBDE) moiety exhibited a long lived emission life time around 12 μs. Ru(II)-polypyridyl systems have been known to exhibit a decrease in emission life time upon elevation of temperature, owing to thermal deactivation from the emissive ^{3}MLCT* to the non-emissive dd* excited triplet state followed by a fast nonradiative decay from ^{3}dd* to the ground state. However, boron incorporated ruthenium(II)-complexes exhibited an unusual temperature independent emission life time over a long range of temperatures, 10.7 μs (280 K)−9.8 μs (330 K). This unique photophysical characteristic was attributed to the involvement of the CT interaction between the vacant p-orbital of the boron atom and π orbital of the aryl group in DBDE ligand, which results in the stabilization of ^{3}MLCT energy with respect to the ^{3}dd energy. It leads to the restriction of thermal activation from ^{3}MLCT to ^{3}dd, and as a result, the long-lived temperature independent emission was observed. They have reported a dual emission from the complex at low temperature (Sakuda et al., 2015).

It was shown that the Ru(II)-DBDE complex possesses spatially-isolated excited ^{3}MLCT states namely T1 and T2, in close proximity in energy (270−290 cm^{-1} estimated at 77 K) and the two excited triplet states exhibited individual emissions below 220 K independently. The T1 state possesses both

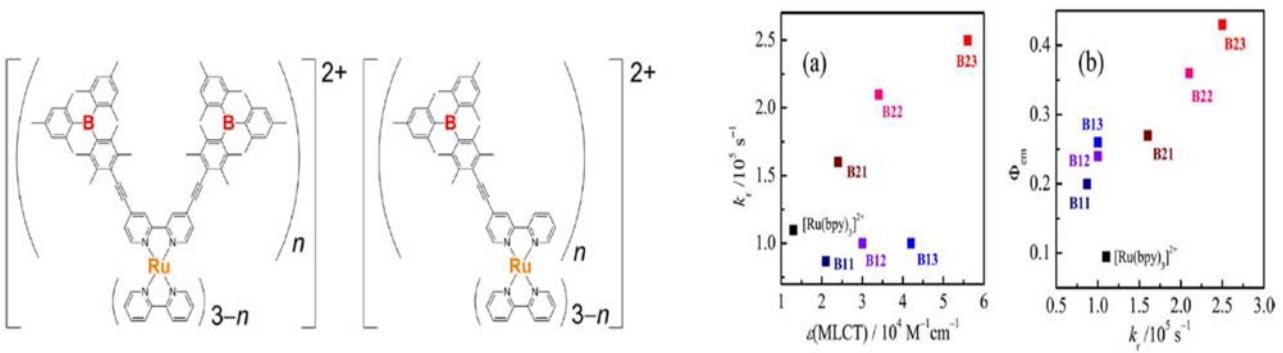

FIG. 7.12 Ru(II) complexes having a triarylborane-appended 2,2′-bipyridine (bpy) ligand. MLCT/LC characters, while T2 state was predominantly MLCT character. The T2 MLCT excited state of the complex exhibit a longer emission life time around 27 μs and became non-emissive above the glass-to-fluid transition temperature of $T_g \approx 220$ K due to strong solvation around the MLCT excited states and subsequent fast non-radiative relaxation to the ground states, while the T1 MLCT/LC excited states exhibit a lifetime around 13 μs irrespective of temperature T: 77−320 K (Fig. 7.14).

In another approach, the photophysical properties of ruthenium complexes have been finely tuned by introducing organic radical as ancillary group onto the bipyridine core. Ito et al. (2017) prepared a novel ruthenium(II) complex containing, 1,5-dimethyl-6-oxoverdazyl group, a stable radical as a substituent (Fig. 7.15) and explored the photophysical properties.

Owing to the presence of free radical, it has been reported that the intersystem crossing ISC in such complexes have been highly accelerated. Since such high acceleration of singlet-triplet transitions are achievable in organic derivatives, containing π-radicals, and metal complexes, hybrid metal-complex-π-radicals becomes ideal choice for development of novel photoactive systems. In comparison with parent complex $[Ru(bpy)_3]^{2+}$, MLCT absorption peak was enhanced and shifted to the lower energy region. The enhancement of MLCT intensity and low energy absorption of the radical complexes can be explained by the electron withdrawing nature of the organic radical moiety, which resulted in lowering the energy π^* orbital of the bipyridine group and enhanced in transition dipole moment. The presence of long-lived emissions in the complex was associated with the reduction of non-radiative deactivation by the ^{3}MLCT level via the ^{3}dd* state, where a large activation energy is associated with the $^3\text{MLCT} \rightarrow {}^3\text{dd}^*$ transition. The co-existence of low-energy/high intense absorption in the UV−visible region and long-lived excited state obtained for the radical complexes are valuable features for their applications as photosensitizers.

Dong et al. (2014) reported that the improvement of optical properties of heteroleptic Ru(II)-polypyridyl complexes can be achieved by incorporating electron donating ancillary ligands. This was established by DFT/TDDFT tools. Density functional theory calculation were done on three previously reported Ru(II)-complexes (El-Shafei et al., 2012), where the experimental data revealed that these novel complexes are red-shifted and have stronger molar absorptivity over the visible range of the solar spectrum extending into the near IR region, with a lower ionization potential (i.e., upshift of the HOMO level) and a reduced HOMO−LUMO energy gap, while preserving the correct band alignment intact. The theoretical calculation showed that inclusion of electron donating conjugated ligands enriches the population of the occupied frontier molecular levels, decreases the ionization potential and the

HOMO−LUMO energy gap. This helps to improve the performance of the sensitizer by reducing the hole-regeneration loss.

Schlotthauer et al. (2017) developed a series of new cyclometalated Ru(II)-complexes bearing tridendate 2,6-di(quinolin-8-yl)pyridine ligands (Fig. 7.16) and their photophysical properties were evaluated.

The primary motive behind the selection of cyclometalated complexes is that the triplet excited state is dominated by (^{3}MLCT) metal to ligand charge transfer character with some admixing of the cyclometalating donor (Motley et al., 2017). The organic subunits (donating/accepting) contribute to the charge separation in HOMO/LUMO levels, leading to charge separation in the excited state. Deactivation of excited state by both radiative and non-radiative influences the spectral properties, life time and energy/electron transfers process and is controlled by strong σ donors or an improved octahedral geometry, which can be achieved by cyclometalated systems (Zhang et al., 2019).

The optical properties of luminescent ruthenium complexes are strongly affected by changes in the polarity and rigidity of their environments. The nature of solvent has a very important significance in photophysical properties of Ru(II)-complex system. A study was carried out by Schneider et al. (2018), which demonstrated an unusually short-lived solvent-dependent excited state in a Ru(II) complex induced by low-lying triplet metal centered MC states.

A ruthenium complex with a half-sandwich geometry [(p-cymene)Ru(Cl)(curcuminoid)] was synthesized and its solvent dependent photophysical properties was investigated (Fig. 7.17). The study revealed a weak and short-lived emission from the initially populated singlet MLCT state and exhibited solvent dependent photo-induced dynamics, where the secondarily populated ^{3}MC state was found to be stabilized by non polar solvents. There is a direct decay from ^{1}MLCT to the ground state in dichloromethane, and in acetonitrile medium, whereas ^{3}MLCT state character was accessible through high polar solvent (DMSO) with a significantly longer ground-state recovery. The presence of the characteristic triplet MC states can be accounted by considering the half-sandwich structure as highly distorted octahedral geometry.

The microenvironment, changes in solvent, viscosity and change in medium from homogeneous to heterogeneous have a significant impact on the photophysics and photochemistry of ruthenium(II)-polypyridine complexes $[Ru(NN)_3]^{2+}$ (NN = 2,2′-bipyridine and its derivatives). The $[Ru(NN)_3]^{2+}$ complexes have been extensively used as probes in micellar media and their photophysical properties vary enormously with the nature of the surfactant and concentration (Sangiliapillai et al., 2016). The photophysical properties of amphiphilic ruthenium(II)-complexes in the presence of micelles (anionic(SDS), cationic (CTAB) and neutral (Triton-X100) have been investigated (Rajkumar et al., 2014) (Fig. 7.18).

There are two possible interactions between the complex and the micelles and these are electrostatic attraction or repulsion and hydrophobic interaction.

In cationic micelles, the luminescence intensity and lifetime increases with increase in [CTAB], which confirms that the electrostatic repulsion is overcome by the hydrophobic interactions between the ligands and cationic surfactant. These binding interactions stabilize the ^{3}MLCT state compared with d-d state in micelles. In the case of anionic micelles, electrostatic interaction between the cationic complexand anionic micelle is predominant, whereas cationic and neutral micelle, hydrophobic interactions play important role in the binding of cationic complexes with micelles. The increase of quantum yield in the presence of micelle was attributed to the decrease in therate of non-radiative decay from excited sate. It has been demonstrated that micellization has a significant effect on relaxation to ground state via the d-d state with k_{dd} values reduced by $\sim$50%.

7.3.1.7 Excited state reactions of ruthenium(II)-complexes

Electron transfer reactions play an important role in the biological systems such as photosynthesis, respiration, and metabolic processes. Understanding the mechanisms of these highly efficient electron transfer processes that take place in biological system is very important that would help us to develop artificial photosynthesis, development of new diagnostic and therapeutic protocols, etc. Ru(II)-complexes are well known systems, which are used to for mimicking these studies. Many Ru(II) based complexes are developed as model compounds that exhibit photoinduced electron transfer systems. The ^{3}MLCT states of $[Ru(NN)_3]^{2+}$ complexes are sufficiently long-lived to undergo bimolecular collisions with other molecules (quenchers) present in the solution (either oxidative or reductive quenching process). During this process, the excited states are rapidly deactivated. The excited-state quenching process can proceed either by energy transfer or electron transfer. The two main factors that determine the rate of electron transfer (ET) between two molecules are the

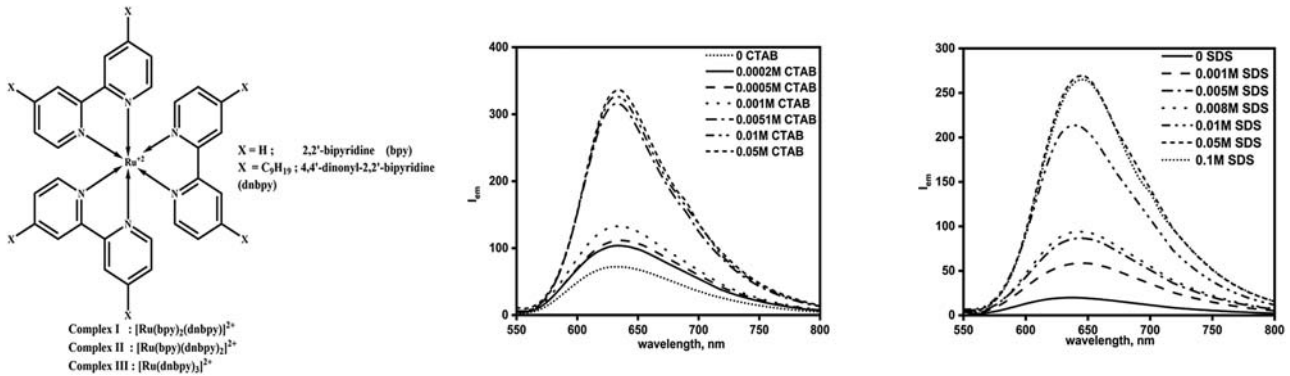

FIG. 7.18 The structure of the $[Ru(NN)_3]^{2+}$ complexes used in the study and the emission spectra of $[Ru(bpy)_2(dnbpy)]^{2+}$ (II) in the presence of cationic micelles, CTAB, and anionic micelles, SDS at different concentrations. *Adapted from Rajkumar, E., Mareeswaran, P.M., Rajagopal, S., 2014a. Photophysical properties of amphiphilic ruthenium (II) complexes in micelles. Photochem. Photobiol. Sci. 13 (9), 1261−1269. With permission.*

extent of the vibrational trapping of electron exchange's by medium and intramolecular vibration.

$$*[Ru(NN)_3]^{2+} + Q \longrightarrow [Ru(NN)_3]^{3+} + Q- \quad (7.10)$$

$$*[Ru(NN)_3]^{2+} + Q \longrightarrow [Ru(NN)_3]^{+} + Q+ \quad (7.11)$$

$$*[Ru(NN)_3]^{2+} + Q \longrightarrow [Ru(NN)_3]^{2+} + Q* \quad (7.12)$$

In Eq. (7.10), the metal complex upon excitation undergoes reduction and it is known as reductive quenching, while Eq. (7.11), represents the oxidative quenching reactions. The complex in the excited state can transfer the excess energy to the acceptor molecule (Eq. 7.12).

The photoinduced electron transfer reactions of the Ru(II)-complexes with different quenchers have been studied (Rajkumar et al., 2011, 2014; Sangiliapillai et al., 2016; Swarnalatha et al., 2011). For example, the photoluminescence quenching of Ru(II)-complexes with quinones can be explained by the oxidative quenching mechanism (Rajkumar et al., 2014). The structure of Ru(II)-complexes and quinones are shown in Figs. 7.19 and 7.20 and the bimolecular quenching rate constant are tabulated in Table 7.1.

The value of quenching rate constant k_q is sensitive to the reduction potential of quinones. It is apparent from the data in Table 7.1 that quinones with higher reduction potentials exhibited higher quenching rate constants, a trend that is indicative of electron transfer quenching. The electron transfer nature of the quenching of $*[Ru(NN)_3]^{2+}$ with phenolate ions and quinone radical has already been established from laser flash photolysis study and the spectrum of phenoxyl radical is already reported (Rajkumar et al., 2011, 2014; Sangiliapillai et al., 2016; Swarnalatha et al., 2011).

According to this scheme, the excited state donor ($*Ru^{II}$) and the ground state acceptor (quinone) molecules diffuse together to form an encounter complex ($*Ru^{II} \ldots Q$). This encounter complex then undergoes a reorganization to reach the transition state, where ET takes place from the donor to the acceptor to give an ion-pair species, ($Ru^{III} \ldots Q^{-}\cdot$), the successor complex. The parameters k_{12} and k_{21} are the diffusion-controlled rate constants for the formation and dissociation of the encounter complex ($*Ru^{II} \ldots Q$), respectively. The k_{23} and k_{32} are the forward and reverse ET rate constants. Apart from the back electron transfer to form the precursor complex (k_{32}), the ion-pair state, ($Ru^{III} \ldots Q^{-}\cdot$) can form the separated species $Ru^{III} \ldots Q^{-}$ (k_{sep}) and undergoes back electron transfer to form the reactants in the ground state (k_{34}).

7.3.1.8 Ruthenium (II) complexes in photodynamic therapy

Photodynamic therapy (PDT) is a globally approved, and non-invasive treatment protocol for various types of cancer, bacterial, fungal, & viral infections, and skin diseases, which induces cell death upon light activation (Mari et al.,

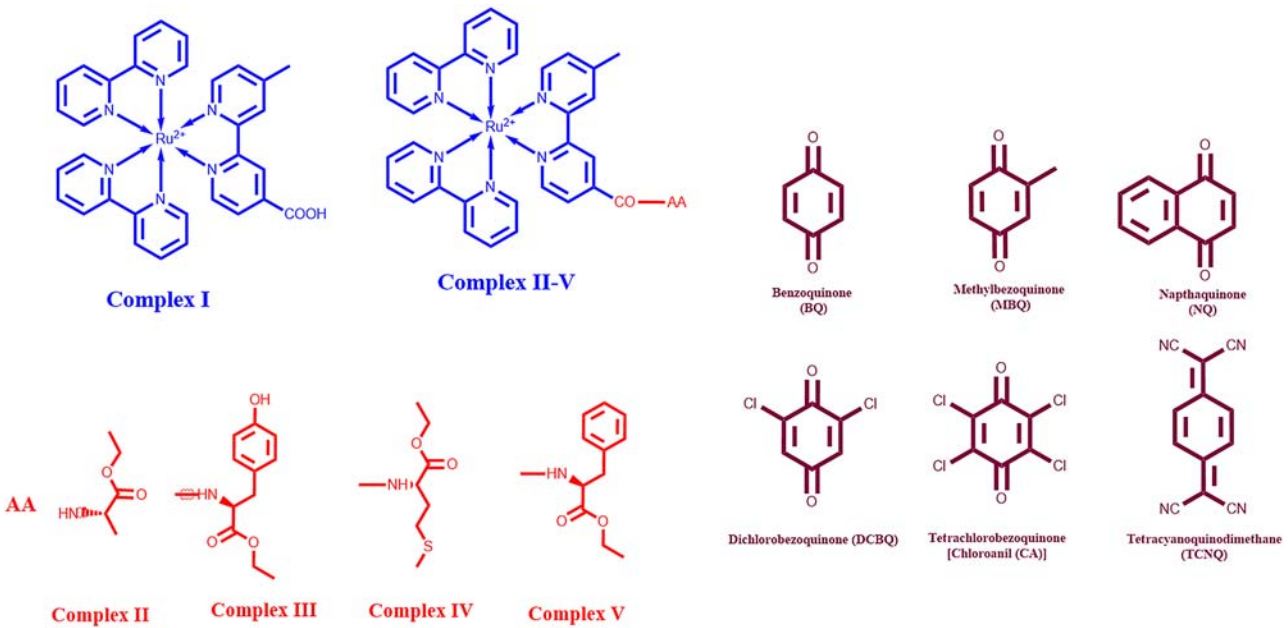

FIG. 7.19 Structure of Ru(II)-complexes and quinones used in the study. *Adapted from Rajkumar, E., Kalayar, S., Paulpandian, M.M., Seenivasan, R., 2014b. Photoinduced electron transfer reactions of ruthenium (II)-Complexes containing Amino acid with quinones. J. Fluoresc. 24 (3), 875–884. With permission.*

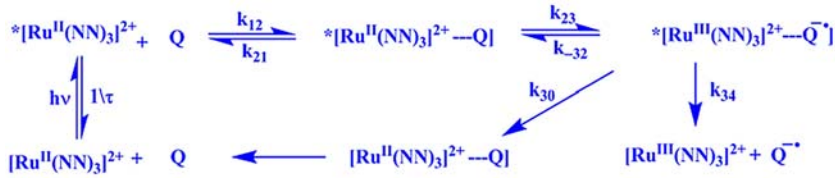

FIG. 7.20 Mechanism for the oxidative quenching of $*[Ru(NN)_3]^{2+}$ with quinines. *Adapted from Rajkumar, E., Kalayar, S., Paulpandian, M.M., Seenivasan, R., 2014b. 2015; Liu et al., 2018; Shum et al., 2019). The PDT consists of basically three components, light, photosensitizer (PS) and molecular oxygen. PDT takes place in two steps.

The mechanism of PDT action is shown in Fig. 7.21. First, a patient is administered with non-toxic PS followed by irradiation of PS at a specific wavelength. The PS absorbs light and reached to excited singlet state S_1, which is unstable. From this state, PS can undergo the intersystem crossing (ISC) process to reach the more stable excited triplet state T_1. After reaching T_1 state, apart from normal deactivation modes, it may influence the biological environment through two different pathways known as Types I and II (Heinemann et al., 2017).

In Type I pathway, an electron or proton is transferred either from/to PS or to/from the biological environment to create a radical anion and its corresponding cation. The generated reactive oxygen species (ROS), induces cell death. Alternatively, via type II pathway, the excited PS transfers its energy to the proximal molecular oxygen to produce short lived highly reactive singlet oxygen which triggers cell death. The most widely adapted pathway is the Type II route (Plaetzer et al., 2009).

The main challenge in PDT is development of PS, that is non-toxic, and it must be able to excite in the optical biological window, i.e., 600–900 nm, since photochemically accessing the PS at a deeply buried spot would be a challenge (Fig. 7.22). The majority of the PS developed so far has several disadvantages: (i) tedious synthesis, (ii) poor water solubility, (iii) poor absorption in biological window, (iv) photobleaching (v) target selectivity and (vi) poor clearance from the body. Due to their excellent photophysical properties and water solubility, absorption in the NIR region (He et al., 2021; Qiao et al., 2021), and target selectivity (e.g., DNA targeting probes) (Shao et al., 2021), Ru(II)-complexes have proved to be preferential PS, which can be finely-tuned by chemically to overcome all the above stated challenges (Li and Chen, 2020; Shen et al., 2021). Clinically approved Ru(II)-complexes used as a photosensitizers in PDT to treat skin diseases, cancer, infections, etc (Banerjee, 2021; Mari et al., 2015).

Recently (He et al., 2021), developed a red-light-responsive Ru(II)-complex photosensitizer for lysosome localization photodynamic therapy. Ru-complex photosensitizer [Ru(terpy) (Cl-7-IVQ)I]$^+$ (terpy = 2,2′:6′,2′-terpyridine, Cl7-IVQ = 5-chloro7-(2-(1,3,3-trimethyl-3H-indol-1-ium-2-yl)- vinyl)quinolin-8-

olate) (Ru−I) using large-conjugated indolinepyridobenzopyrans as the ligand was synthesized (Fig. 7.23). The activation of the photosensitizers was achieved using 660 nm red light. Ru(II)-complexes was quickly internalized into cancer cells and seen to get accumulated in lysosome. Under irradiation, the complex drastically suppressed the cancer cells.

7.3.1.9 Ru(II)-complexes in dye- sensitized solar cell (DSSC) applications

The role of Ru(II)-center is similar as in the case of PDT. They act as dyes to sensitize the semiconductor component in the solar cell (Pashaei et al., 2016). A typical dye sensitized solar cell consists of a mesoporous layer of a semiconductor TiO_2 nanoparticles, with a dye anchored onto it, which acts a sensitizer to harvest light photons and convert them to an electric current. A redox mediator commonly used in DSSC is iodide/triiodide (I^-/I_3^-) couple, and a counter electrode (CE). The working principle of DSSC is depicted in Fig. 7.24. The sensitizer dye is the most fundamental and important component that governs the performance of the DSSCs. Among various types of photosensitizers, ruthenium-based dyes are widely used due to their suitable ground- and excited state potentials and broad MLCT absorption bands. An effective sensitizer plays an important role of facilitating a favorable electron injection into the conduction band (CB) of a semiconductor (Hagfeldt et al., 2010).

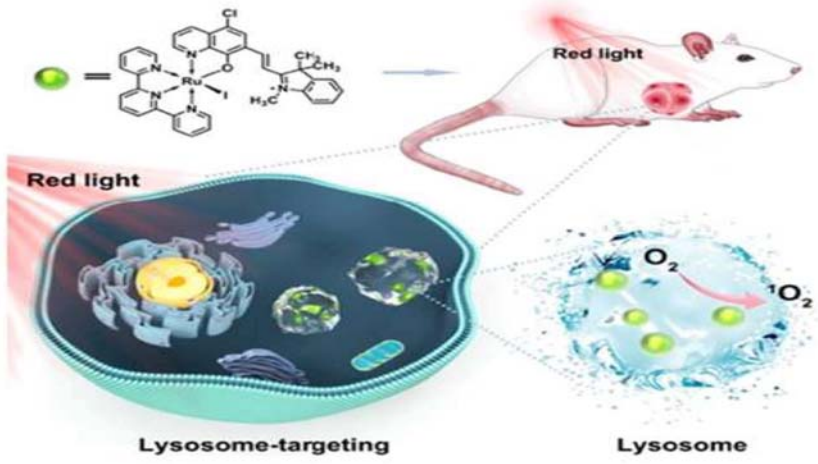

FIG. 7.23 Schematic illustration of the PDT effect toward a tumor-bearing mouse model using Ru(II) with red light irradiation. *Adapted from He, G., Xu, N., Ge, H., Lu, Y., Wang, R., Wang, H., et al., 2021. Red-Light-Responsive Ru complex photosensitizer for lysosome localization photodynamic therapy. ACS Appl. Mater. Inter. 13 (17), 19572−19580. With permission.*

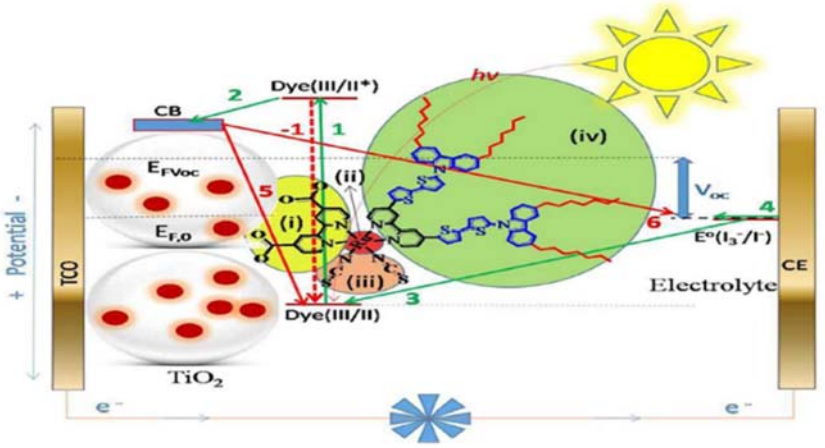

FIG. 7.24 Schematic representation of working principle of dye- sensitized solar cells (DSSCs). *Adapted from Pashaei, B., Shahroosvand, H., Graetzel, M., Nazeeruddin, M.K., 2016. Influence of ancillary ligands in dye-sensitized solar cells. Chem. Rev. 116 (16), 9485−9564. With permission.*

An ideal photosensitizer for the DSSC must fulfill the following conditions.

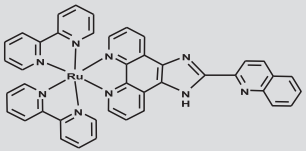
(i) It should have panchromatic absorption in the solar spectrum i.e., visible to near IR region,
(ii) Sufficiently high molar extinction coefficient
(iii) Efficient electron injection from the lowest unoccupied molecular orbital to the conduction band before the deactivation of the sensitizer from the excited state, and
(iv) Thermal and chemical stability in the ground and oxidized states.

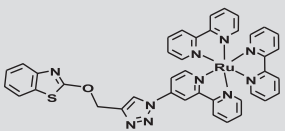
Ru(II) complexes have exhibited strong candidature as sensitizers due to their remarkable photophysical properties with a power conversion efficiency around 11%. The rational modification of ligand is one way of improving the efficiency of Ru(II)-complexes as photosensitizers. The modifications include incorporation of aliphatic, aromatic or both moieties on the pyridyl core. Recently, Pashaei et al. (2016), accounting the possible novel and rapidly expanding families of chelating ancillary ligands bearing 2,2′-bipyridyl, 1,10-phenanthroline, dipyridylamine, carbene, pyridyl-benzimidazole, pyridyl-azolate, and other miscellaneous aromatic ligands that show a potentially enhanced performance and stability of DSSCs.

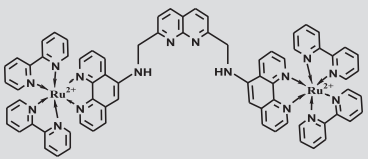
7.3.1.10 Ru(II)-complexes as sensors and for imaging applications

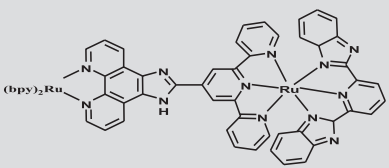
Owing to remarkable photophysical property of Ru(II)-complexes, these were much used as probes for sensor and imaging of biological and environmental

systems in last few decades (Shum et al., 2019; Patra et al., 2019). Sensor and imaging based on absorbance and luminescence is highly desirable due to their very high sensitivity i.e., detection of analyte in nano level or ppm level concentrations could be achieved, with the use of very low concentration of probes. The selectivity and sensitivity of the probes are designed by selecting appropriate peripheral functional groups placed on the ligand architecture (Kumar et al., 2021). The responses of the probe can be either turn off or turn on their luminescence, shift in absorbance and emission wavelength upon interaction with analyte molecule. These responses are generated by various processes such as quenching of luminescence (energy/electron transfers), association and proton transfer between the probe and analytes. Few recently developed Ru(II)-based sensors and their detection of analytes are tabulated in Table 7.2.









7.3.1.11 Photocatalysis of ruthenium(II)-complexes

The photophysical features of Ru(II)-complexes have opened up new possibilities for using them as catalyst in light driven chemical reactions like water oxidation, hydrogen generation, carbon dioxide reduction, etc. In order to meet the global energy demand, artificial systems were developed to mimic the natural photosystems and other processes. There are three key components required to perform water oxidation; light photosensitizer (PS), water oxidation catalyst (WOC) and a sacrificial electron acceptor. A typical mechanism of water oxidation is shown in Fig. 7.25, where A is the sacrificial electron acceptor such as $S_2O_8^{2-}$ or $Co^{III}(NH_3)_5Cl$, Ru_p is the PS usually $[Ru(bpy)_3]^{2+}$and Ru_c is the WOC. The stability of catalyst in aqueous medium, turn over frequency (TOF), turn over number (TON) and low catalytic overpotential are crucial factors for the complex to act as a efficient WOC in water splitting reactions (Xue et al., 2015).

A number of high-valent metal complexes of the first *d* block series as well as heavier transition metals have been reported to show catalytic activity for the oxidation of water to produce molecular oxygen. Among the transition metal complexes, ruthenium-complexes have shown very high activity toward water oxidation. Several ruthenium based WOC successfully prepared and few of them are shown in Fig. 7.26. The efficiency of the catalyst has strong influence on the nature of ligand around the ruthenium center in the complexes.

Patel et al. (2017) reported the influence of electron withdrawing pyridyl substituted terpyridine ligand-based Ru-complexes on the rate of generation of oxygen by chemical and photochemical methods. The $[Ru(tpy)(bpy)(OH_2)]^{2+}$, $[Ru(2\text{-py-tpy})(bpy)(OH_2)](PF_6)_2$, $[Ru(3\text{-py-tpy})(bpy)(OH_2)](PF_6)_2$ and $[Ru(4\text{-pytpy})(bpy)(OH_2)](PF_6)_2$ (bpy = 2,2′-bipyridine; tpy = 2,2′,6,2″-terpyridine) complexes were prepared and their photocatalytic water oxidation properties were evaluated. The free nitrogen on the pyridine ring gets protonated at pH 1, and acts as an electron withdrawing group. The electron withdrawing ability of

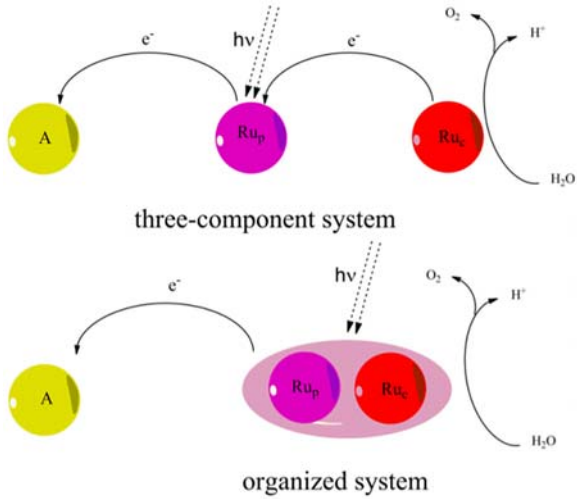

FIG. 7.25 Illustration of the mechanism of water oxidation catalysis. *Adapted from Xue, L.X., Meng, T.T., Yang, W., Wang, K.Z., 2015. Recent advances in ruthenium complex-based light-driven water oxidation catalysts. J. Photochem. Photobiol. B Biol. 152, 95–105. With permission.*

the pyridine in ortho− and para−position is comparatively less with respect to 3-py-tpy ligand, due to the distribution of partial positive charge on the nitrogen and carbon atoms of the pyridine ring and acts as better catalyst in chemical and photochemical water oxidation reactions. Designing of catalyst with heteronuclear systems is another strategy to enhance water oxidation process. Aratani et al. (2017) developed a dual function photocatalyst based on cyano-bridged heteronuclear metal complexes of the type, $(M^{2+}[Ru^{2+}(CN)_4(bpy)]$; where $M^{2+} = Ni^{2+}$, Fe^{2+} and Mn^{2+} for water oxidation. Here, the catalyst acts as both; photosensitizer and photocatalyst. These catalysts integrate both visible-light activated photosensitizer and catalytic units for photocatalytic reduction of O_2 to H_2O_2 and for oxidation of H_2O.

The $Ni[Ru(CN)_4(bpy)]$ complex exhibit a high efficient photocatalytic water oxidation catalyst than other complexes and the proposed mechanism is shown in Fig. 7.27.

Hydrogen evolution reaction is also an important process that utilizes Ru(II)-complexes. The natural hydrogen production process suggested a viable method of collecting, converting, and storing energy via photocatalytic reduction of water. The photocatalytic hydrogen reduction systems consist of a PS that absorbs light and transfers an electron from excited state to the catalyst, wherein water is reduced to H_2. A sacrificial electron donor or reducing agent is needed to restore the PS. A photocatalytic hydrogen evolution reaction driven by red light was demonstrated using a ruthenium quaterpyridine complexes (Fig. 7.28), which having extensive π conjugation (Rousset et al., 2017).

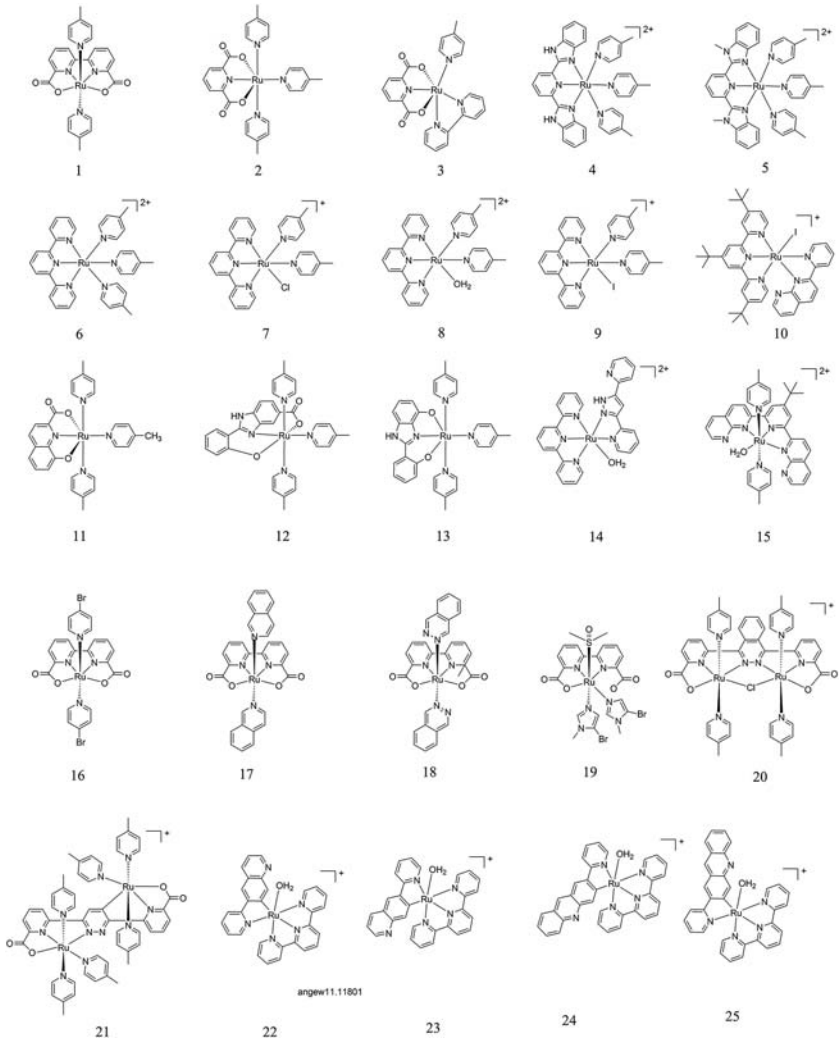

FIG. 7.26 Structures of the ruthenium complex-based WOCs. *Adapted from Xue, L.X., Meng, T.T., Yang, W., Wang, K.Z., 2015. Recent advances in ruthenium complex-based light-driven water oxidation catalysts. J. Photochem. Photobiol. B Biol. 152, 95−105. With permission.*

The average twist angle between the 4-pyridyl moiety and the bipyridine core is 30 degrees in the solid-state, which allowed an inter-annular delocalisation in the ground state and excited state. In the thermally-equilibrated triplet MLCT state, extended π-system of fully planar 4-pyridyl groups give rise to high quantum yields and excited life time of ruthenium quaterpyridine complex, $[Ru(qpy)_3]^{2+}$ (Φ = 23; lifetime = 1780 ns) as compared to

$[Ru(bpy)_3]^{2+}$. A maximum turn over frequency (TOF) of 650 mmol $mol_{PS}{}^{-1}min^{-1}$, was observed for qpy complex, whereas the TOF of bpy complex was only about 30 mmol $mol_{PS}{}^{-1}min^{-1}$, when excited by red light with wavelength of 630 nm. The efficiency of the $[Ru(qpy)_3]^{2+}$ complex is due to the possible spatial interactions with the photocatalyst through the nitrogen heteroatoms in the pendant pyridines, when compared to the phenyl analogs.

Multinuclear ruthenium complexes are another class of PS used for photocatalytic hydrogen evolution, Veikko et al. (2013) synthesized mononuclear and dinuclear ruthenium(II)-complexes and evaluated their hydrogen evolution efficiency Fig. 7.29.

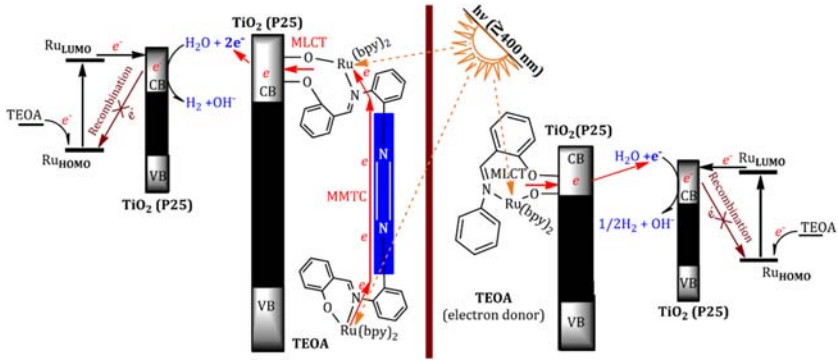

FIG. 7.29 Photoinduced electron transfer cycle of Ru(II)-complex and the mechanism of hydrogen generation. *Adapted from Veikko, U., Zhang, X., Peng, T., Cai, P., Cheng, G., 2013. The synthesis and characterization of dinuclear ruthenium sensitizers and their applications in photocatalytic hydrogen production. Spectrochim. Acta Mol. Biomol. Spectrosc. 105, 539–544. With permission.*

It was found that the dinuclear system was superior in catalytic efficiency over the mononuclear system. This is attributed to the "antenna effect", where additional charge transfer mechanism through metal-to-metal charge transfer (MMCT) takes place than mononuclear complex. The sensitizer is linked to TiO_2 via flexible oxygen bridges and hydrogen bonds, which spontaneously changes the coordination based on the circumstances of the ground state and oxidation state of ruthenium unit. It is evident that the performance of the catalysis is based on both; anchoring ligands and antenna effect. Heterometallic multinuclear systems are also reported as highly efficient PS for photocatalytic hydrogen evolution. Das et al. (2017) developed supramolecular assemblies of the type $[Ru(dceb)_2(\mu\text{-bisbpy})MCl_2](PF_6)_2$ and $[Ru(bpy)_2(\mu\text{-bisbpy})MCl_2](PF_6)_2$ (where M = Pd or Pt, dceb = diethyl-2,2′-bipyridine-4,4′-dicarboxylate, bpy = 2,2′-bipyridine and bisbpy = 2,2′:5′,5″:2″,2‴-quaterpyridine). The photocatalytic investigations of these complexes were dependent on the nature of the peripheral ligand, the catalytic center, and the amount of water present in the photocatalytic mixtures.

Recently, several researchers have reported the photocatalytic reduction of CO_2 using Ru(II)-complexes (Cauwenbergh and Das, 2021). Hawecker et al. (1985) reported for the first time the photocatalytic reduction of carbon dioxide to formate using $[Ru(bpy)_3]Cl_2$, when triethanolamine was used as a sacrificial oxidant. The catalytic process is strongly influenced by the nature of ligands around the catalytic metal center and PS, solvent, and the interaction between the catalyst and the PS (separated or linked).

Yoshitomi et al. (2015) have done pioneering work on photocatalytic carbon dioxide reduction using Ru(II)-semiconductor hybrid system. A hybrid material consisting of perovskiteoxynitride semiconductor and binuclear

ruthenium complex as photocatalyst was developed that produced formic acid via CO_2 reduction. The mechanism of CO_2 reduction is depicted in Fig. 7.30.

Use of visible-light-absorbing semiconductor and metal complex have attracted attention as efficient photocatalysts for CO_2 reduction with high selectivity in products. They developed a defect fluorite-type Ln−Ta oxynitrides $LnTaO_xN_y$ (Ln = Nd, Sm, Gd, Tb, Dy and Ho) and examined it as a semiconductor component in a hybrid photocatalyst system combined with silver nanoparticles as promoter and binuclear ruthenium(II)-system. $TbTaO_xN_y$ gave the highest efficiency for CO_2 reduction under visible light ($\lambda > 400$ nm), with a turn over number of 18 and high selectivity to formate above 99%. The physicochemical analysis shows that the presence of high crystalline structure and highly negative conduction band potential of $LnTaO_xN_y$ contributed to the higher activity of the hybrid photocatalyst.

Supramolecular assembly is another method for improving the photocatalytic efficacy of the systems. Fabry et al. (2020) developed a Ru(II)−Mn(I) supramolecular photocatalyst consisting of a redox photosensitizer, catalyst, and the bridging ligand for CO_2 reduction (Fig. 7.31). The supramolecular assembly constituted 1:1 ratio between the PS and catalyst units, which showed higher activity for HCOOH formation in comparison to the corresponding mixed system of mononuclear complexes.

In summary, Ru(II)-complexes are versatile systems, which can be fine-tuned on need to need basis. It is clear that the photophysics and photochemistry of ruthenium complexes can be tailor made by strategic designing its coordinating ligands. Ruthenium(II)-complexes have exhibited their potential in a large spectral window ranging from UV-Vis-near IR, opening wide scope of utility, in the field of photodynamic therapy, solar cells, and photocatalysis, etc.

7.4 Coordination compounds of osmium complexes

The photophysics of osmium complexes are similar to that of ruthenium complexes. The photophysics of osmium complexes are well exploited in the field of OLED, phosphorescent materials, photodynamic therapy, imaging, and diagnosis, etc. Fine tuning of the ligands and chemical architecture around the osmium metal core can results in near IR and far visible probes for various applications in the biological window.

7.4.1 Photoactive oxidation states of osmium complexes

Osmium complexes are reported to be photoactive in four oxidation states, which are Os(II), Os(III), Os(IV) and Os(VI). The most commonly observed oxidation state is 2+ oxidation state. The photophysics of the parent complex of this series, $[Os(bpy)_3]^{2+}$ (bpy = 2,2′-bipyridine) has been thoroughly investigated Yersin et al. (1990). It was established that the emissive state in

Os(II) complexes arises due to metal to ligand charge transfer (MLCT). The position of these states depends on the ligand field strength (Δ) of the heavy metal. Osmium(II)-complexes have larger Δ values than Ru(II)-complexes with the same ligand field. This raises the energy of the non-emissive d−d states, which reduces thermal deactivation of the MLCT states. As a result, Os(II)-complexes have greater photostability compared to Ru(II)-complexes. However, considering the differences in oxidation potentials and larger spin-orbit coupling, Os(II)-complexes generally have lower emission energies and shorter excited-state life times than Ru(II)- analogs. These disadvantages were addressed in a recent study by Zammit et al. (2012) by substituting one or more polypyridyl type ligands with stronger π −acceptor moiety, such as diphosphine or diarsine, ligands.

Ito et al. (2014) studied the effect of rigid medium such as poly(ethylene glycol)dimethacrylate monoliths on the photophysical properties of series of Os(II)-polypyridyl complexes. Higher energy emissions from the metal-to-ligand charge transfer (MLCT) excited states of a series of polypyridyl Os(II)-complexes were observed at the solution to film transition. It is due to the frozen (rigid) nature of the film and the inhibition in the local medium dielectric to respond to the change in charge distribution induced by the photoexcitation. This led to an increase in emission energies in the film, longer excited-state life times and enhanced emission quantum yields, consistent with the energy gap law. Apart from the mononuclear Os(II)-complexes, one would also bring remarkable photophysical features by incorporating multi metal polynuclear complexes. With regard to metal-metal interactions in mixed valence states of the intramolecular electron or energy transfer process, the polynuclear heteroleptic complexes have displayed superior photophysical properties compared to mononuclear complexes. Boonyavong et al. (2014)

prepared an unsymmetrical dinuclear ruthenium osmium 2,2′-bipyridine complexes and studied their photoinduced electron transfer reactions.

The incorporation of anionic ligands into the cationic transition-metal complex systems is a workable strategy to develop neutral emissive materials. Chu et al. (2014) developed a new class of neutral bis(isocyanoborato) bis(bipyridyl) Os(II)-complexes with the general formula of $[Os(N{-}N)_2(CNBR_3)_2]$ (N−N = bpy, 4,4-Me_2bpy; R = C_6F_5,C_6H_5), Unlike the mostly reported neutral bis(bipyridyl)Os(II) complexes (Fig. 7.32), which are very weak or non-emissive, these isocyanoborato complexes exhibited an intense orange to red luminescence with maxima in the range of 610−660 nm with a luminescent quantum yield up to 0.09 at RT. The emission profile of the complexes were very sensitive to the change of the electronic properties of the borane, which is in accordance with the π-accepting ability of the isocyanoborate ligands, $CNB(C_6F_5)_3 > CNB(C_6H_5)_3$. This is due to the variation of energy level of the dπ(Os) orbital, resulting from the Os−$CNBR_3$ interaction.

Os(III)-complexes were used as oxidants in analysis of oxidizable analytes by photoluminescence followed by electron transfer (PFET) based detection methods (Jung et al., 2006). To date, $[Ru(bpy)_3]^{3+/2+}$ and $[Os(bpy)_3]^{3+/2+}$ were used in PFET applications as oxidants for the quantitative determination of proteins, small organic molecules, and other biomolecules. The $[Os(bpy)_3]^{3+}$ was found to be a more superior PFET reagent than $[Ru(bpy)_3]^{3+}$owing to its fast electron-transfer exchange rate and greater stability in 3+ oxidation state. The detection strategy is based on reduction of oxidant by chromatographic eluent to generate a measurable luminescence signal. Patel et al. (2014) demonstrated that tetramethyl-1,10-phenanthroline osmium(III) complex in neutral pH displayed a photoluminescence followed by electron-transfer, which was exploited in the detection of acetaminophen in urine and pharmaceutical formulations (Fig. 7.33).

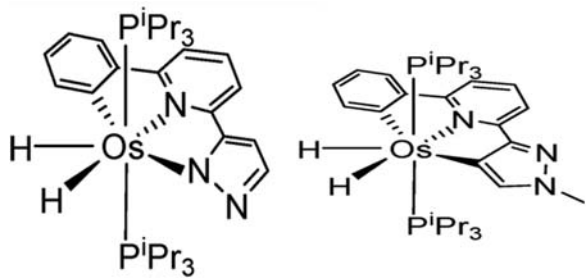
The photophysics of d^2 metal complex system is very important in the design of photooxidants. The d^2 metal complexes coordinated to heteroatoms are capable of forming multiple bonds such as oxygen and nitrogen usually having a long-lived and high energy $(d_{xy})^1(d\pi^*)^1$ ($d_{\pi^*} = d_{xz}$, d_{yz}) excited states, which makes them suitable for photocatalysis or photo-induced atom transfer processes (Li et al., 1992; Che et al., 1987). Osmium(IV)-complexes may offer a great deal of flexibility for color tuning, in addition to being more difficult to oxidize than osmium(II) derivatives. Furthermore, OLEDs utilizing Os(IV)-based emitters should be more immune from the formation of an exciplex in the device (Chou and Chi, 2006). Osmium(IV)-based phosphors are exhibiting promising potential application, and their development is certainly challenging. However, emissive Os(IV)-complexes have received little attention, due the fact that they are difficult to prepare several of their geometrical structures are close in energy. The facile exchange of structural form between them allowed the dynamic quenching of the phosphorescence. As a result, emissive Os(IV)-complexes reported up to now are characterized by their low stability and quantum efficiency lower than 0.06. Hence, it is highly demanding to overcome to major challenges; increasing the stability of Os(IV) complexes and the quantum yield of their emissions (Crespo et al., 2012; Eguillor et al., 2015).

Pincer ligands are excellent candidates to stabilize osmium(IV) species with a pentagonal-bipyramidal structure, since this makes two consecutive angles close to 72 degrees, creating an ideal L−M−L angle in the equatorial plane of the bipyramidal structure and fluxional relaxations processes can be restricted (Choi et al., 2011; Benito-Garagorri and Kirchner, 2008). Alabau et al. (2017) reported the preparation of phosphorescent osmium(IV)-complexes with 2-phenyl-6-(1H-pyrazol-3-yl)pyridine and its functionalized derivatives as dianionic and monoanionic N,N,C and C,N,C-pincer ligands, respectively (Fig. 7.34). Osmium(IV)-complexes containing these pincer ligands are phosphorescent emitters in the green to red region with quantum yields (∼0.45−0.5) that are unusually high compared to the previously reported osmium(IV)-complexes with narrow emissions. This is a consequence of the rigidity imposed by the pincer ligand, which reduces both; the energy dissipation by means of dynamic processes and the difference between the excited-state and ground-state structures.



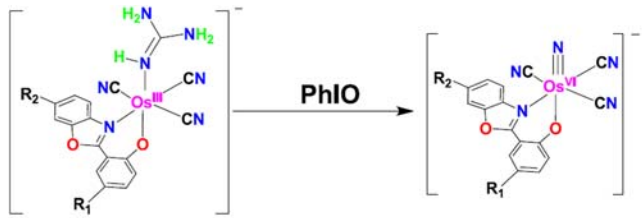


FIG. 7.34 Osmium complexes containing N,N,C and C,N,C-pincer ligands. *Adapted from Alabau, R.G., Esteruelas, M.A., Olivan, M., Onate, E., 2017. Preparation of phosphorescent Osmium (IV) complexes with N, N′, C-and C, N, C′-pincer ligands. Organometallics 36 (9), 1848–1859. With permission.*

The d^2 Os(VI)-complexes are known to be luminescent. Che et al. (1989) reported the synthesis, photophysical and photochemical properties of Os(VI)-centric nitrido and imido complexes. The distorted octahedral complex $[Ph_4As]_2[\ Os^{VI}(CN)_5N]$ showed intense photoluminescence at 550 nm on excitation at 300–400 nm at room temperature. The emission mainly originated from metal-centered ligand-field $^3[(d_{xy})^1(d_{\pi^*})^1]$ excited states.

Luo et al. (2020) developed a series of Os(VI) complexes of the type $[Os^{VI}(N)\ (NO_2\text{-L})\ (CN)_3]^-$ [HNO_2-L = 2-(2-hydroxy-5-nitrophenyl)benzoxazole] with varying substitution on the bidentate ligand L. All the prepared Os(VI)-complexes exhibited a distorted octahedral geometry, with one nitrido ligand being located at the axial site trans-to the phenolate O donor while maintaining the three CN ligands in *mer* configuration (Fig. 7.35). The series

R_1 = CF_3, R_2 = H (7); R_1 = NO_2, R_2 = H (8);
R_1 = NO_2, R_2 = Me (9); R_1 = NO_2, R_2 = Cl (10);

FIG. 7.35 Osmium(VI)-nitrido complexes. *Adapted from Luo, L.J., Su, Q.Q., Cheng, S.C., Xiang, J., Man, W.L., Shu, W.M., et al., 2020. Tunable luminescent properties of tricyanoosmium nitrido complexes bearing a chelating O^ N ligand. Inorg. Chem. 59 (7), 4406–4413. With permission.*

of complexes exhibited a strong luminescence both in the solution and in solid state. The luminescence of these nitrido complexes are attributed to the ^{3}LML'CT [π(N^O)$\rightarrow$dπ*(Os$\equiv$N)] phosphorescence emissions. Introduction of strong electron-withdrawing groups such as NO_2, CH_3COO and CF_3, weakens the π-donor properties of the phenolate moiety, which effectively increases the relative contribution of LMLCT in their emissive states resulting in a significant enhancement of LMLCT luminescence.

7.4.2 Near IR phosphorescent osmium complexes

Phosphorescent materials have been designed, and explored because of their wide range of applications (Evans et al., 2006) such as phosphor materials in organic light emitting diodes (OLED), biological probes for theranostics (Monro et al., 2018; Liu et al., 2018), signaling, imaging, and wound healing, etc. The near IR wavelength is considered to be the biological window, as it could penetrate deep through the skin, and tissues. Development of novel phosphorescent probes is the focus of researchers owing to their numerous applications. Some strategies for NIR emission comprise, the use of the donor-acceptor organic dyes, semiconductor quantum dots, conjugated oligomers, and coordination complexes, etc. Os(II)-complexes are well known for their phosphorescent photophysical characteristics. Their structural design can be finely tuned to exhibit panchromatic emission. Though there are several reports on the Os(II)-based panchromatic emitters in the literature, this discussion focus mainly on near IR/far visible phosphorescent Os(II)-complexes (Glazer, 2017). Lee et al. (2009) have done pioneering work on the development of Os(II)-phosphors. A series of new neutral Os(II)-complexes with highly conjugated isoquiniolinyltriazolate chelate was prepared to obtain phosphors that emit at longer wavelength region. Unlike, the Pt(II)-based red emitters, the Os(II)-counterparts use their lower energy MLCT contribution to further red shift the emission, whereas the former uses the intermolecular π-π stacking interaction to lower the emission gap due to the square planar geometry, but in the case of Os(II)-phosphors, the π-π stacking is not realised because of their octahedral configuration. [Os(ibtz)$_2$(PPhMe$_2$)$_2$](5-(1-isoquinolyl)-3-tert-butyl-1,2,4-triazole $-$ibtz) showed an absorption at 468 nm assigned to the spin-allowed $^1\pi\pi$* transition mainly associated with the chromophoric ligand isoquinolyl-triazolate. The next absorption band was observed at 522 nm assignable to a spin allowed ^{1}MLCT transition, and broadened absorption band at the longer wavelength can reasonably be ascribed to a mixed state involving both; spin-orbit coupling enhanced $^3\pi\pi$* and ^{3}MLCT transitions. The T_1-S_0 transition (phosphorescence) occurred at 805 nm, which possess contribution from both spin-forbidden π-π* and MLCT characters. The maximum external quantum efficiency obtained was 1.5%.

Chen et al. (2010) reported the use polypyridyl ligand architectures in achieving highly efficient energy/electron transfers for the development of

solid state near IR phosphorescent Os(II) complexes. Insertion of appropriate conjugated π bridges between these complexes, resulted in rod-like donor-sensitizer-acceptor molecular assemblies, which facilitates an efficient energy/electron transfer process. The typical approach takes up the advantage of the substituent effects for tuning the energy gap between ^{3}MLCT and ^{3}MC states, which involves the insertion of judiciously selected heterocyclic substituents to the pyridyl chelates (Fig. 7.36). Further, an increase of the ligand bite angle was attempted to make the complex adopt a less distorted octahedral arrangement so that the increased ligand field strength and reduced non-radiative decay can be achieved.

The charge neutral Os(II)-complex [Os(fpbpyk)$_2$] [fpbpyk = [5-(trifluoromethyl)pyrazol-3-yl](2,2′-bipyrid-6-yl) ketone] was prepared by the treatment of osmium(III) trichloridetrihydrate with 2 equivalents of the terdentate chelate fpbpykH. The resulting complex was non-luminescent in solution (CH_2Cl_2 or MeOH) at room temperature, but exhibited near IR phosphorescence at 994 nm in solid state at RT.

Near IR phosphors is not restricted to OLED applications only, but they play a vital role in biological science as sensors, for imaging and therapeutics. Zhang et al. (2017) developed a novel Os(II)-NIR phosphorescent probe for lysosomes tracking and photodynamic therapy. The complex showed MLCT absorption at 488 and 683 nm, and exhibiting NIR emission centered between 700 and 850 nm. Due to strong spin-orbit coupling induced by heavy Os(II), the spin-forbidden ^{3}MLCT absorption bands were seen in the NIR region. Smitten et al. (2020) reported the trizole based Os(II)-complexes that displayed strong red/near-IR luminescence. The phosphorescence emission was well exploited in the photodynamic antimicrobial activity against *saureus* and super high resolution cellular imaging. The prepared complexes $[Os(N^\wedge N)_3]^{2+}$ (N^N = 1-benzyl-4-(pyrid-2-yl)-1,2,3-triazole (**I**); 1-benzyl-4-(pyrimidin-2-yl)-1,2,3-triazole (**II**), and 1-benzyl-4-(pyrazin-2-yl)-1,2,3-triazole (**III**) displayed a prominent spin-forbidden ground state to triplet metal-to-ligand charge transfer state absorption bands enabling excitation as low as 600 nm for *fac/mer*-complex (**III**) and an emission in the deep-red/near-IR regions was observed for the aqueous solution of the complexes. Cellular uptake studies within MRSA cells showed antimicrobial activity with greater toxicity for the meridional isomers in each case, with *mer*-(**I**) exhibiting the greatest potency.

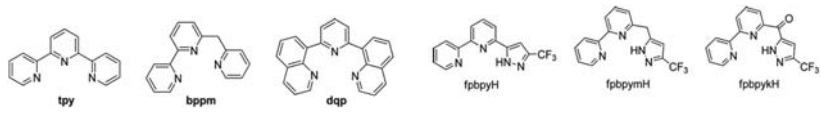

FIG. 7.36 Polypyridyl chelating ligands with conjugated π bridges. *Adapted from Chen, J.L., Chi, Y., Chen, K., Cheng, Y.M., Chung, M.W., Yu, Y.C., et al., 2010. New series of ruthenium (II) and osmium (II) complexes showing solid-state phosphorescence in far-visible and near-infrared. Inorg. Chem. 49 (3), 823−832. With permission.*

Super-resolution imaging experiments demonstrated the binding of *mer*- and *fac*-(**I**) to bacterial DNA with high Pearson's colocalisation coefficients (up to 0.95 using DAPI). The phototoxicity studies revealed that the complexes exhibited a higher antimicrobial activity upon irradiation with light. In another study, a series of Os(II) complexes $[Os(bpy)_{3-n}(pytz)_n][PF_6]_2$ (bpy = 2,2-bipyridyl, pytz = 1-benzyl-4-(pyrid-2-yl)-1,2,3-triazole, with n = 0, 1, 2, and 3) were prepared and optoelectrically characterized. These complexes exhibited a strong red phosphorescence (Omar et al., 2018). The pyridyltriazole complexes exhibited phosphorescence in the biologically transparent red to near-IR region of the spectrum in aqueous solution or in acetonitrile solution through low energy excitation into spin-forbidden direct ^{3}MLCT bands. The homoleptic tris(pyridyltriazole) complex (with n = 4) was brightly emissive ($\lambda_{em} = 614$ nm) and undergoes cellular uptake in two cancer cell lines with likely lysosomal and endosomal localization.

7.4.3 Photophysics of osmium complexes on surfaces

The interfacial electron-transfer dynamics in the construction of these solar cells is an area of intense research. Sensitization of TiO_2 electrodes with molecular chromophores form the basis of efficient solar energy conversion in regenerative photoelectrochemical cells, where the anchoring of chromophores onto the semiconductors was achieved by connecting them covalently on to the semiconductor surfaces (Asbury et al., 2001). Ru/Os-polypyridyl complexes have been used extensively by various researchers as the prospective photosensitizer molecule for the development of dye-sensitized solar cell (DSSC). Owing to their lower energy absorption in the visible region, the Os(II)-polypyridyl complexes may be more suitable for this purpose as there, they may offer a lower-energy absorption band and a lower $M^{II/III}$ oxidation potential was also obtained; thereby, an improved performance in photoelectrochemical energy conversion can be achieved (Kalyanasundaram, 1991). Further, the large spin-orbit coupling effectively promotes an intersystem crossing from singlet excited states to lower triplet emitting states (Ramakrishna et al., 2001). Verma et al. (2008) demonstrated the interfacial electron-transfer dynamics on TiO_2 and ZrO_2 semiconductor nanoparticle surface sensitized by novel catechol derivatives of Os(II)-polypyridyl complexes (Fig. 7.37). This group previously established that the deprotonated catecholate moiety binds strongly to TiO_2 through the formation of a five-member chelate ring.

Both these complexes exhibit two strong MLCT absorption bands in the visible region that are ascribed to the ^{1}MLCT (spin allowed) and ^{3}MLCT (spin forbidden) transitions and with an emission maximum around 650−700 nm. The optical absorption studies revealed that both these complexes form charge transfer (CT) complexes with TiO_2 and ZrO_2 (higher band gap) nanoparticles. Photoinduced electron injection takes place from the Os(II)-complexes to the

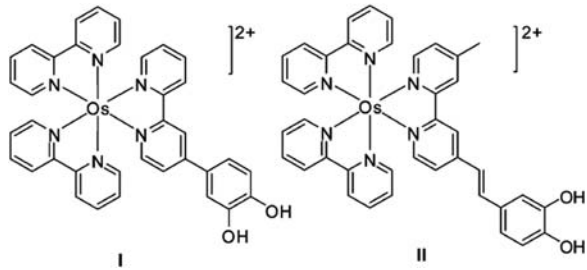

FIG. 7.37 Novel catechol derivatives of Os(II)-polypyridyl complexes. *Adapted from Verma, S., Kar, P., Das, A., Palit, D.K., Ghosh, H.N., 2008. Interfacial electron-transfer dynamics on TiO_2 and ZrO_2 nanoparticle surface sensitized by new catechol derivatives of Os (II)-polypyridyl complexes: Monitoring by charge-transfer emission. J. Phys. Chem. C 112 (8), 2918–2926. With permission.*

conduction band of TiO_2 and surface states of ZrO_2 nanoparticles following excitation of the respective Os(II) catecholic complexes. The ligands were strategically designed to ensure an efficient anchoring on the semiconductor surface and to achieve highly efficient interfacial electron transfer also for solar cell applications.

7.4.4 Photosensitizers for photodynamic therapy

The efficiency of PDT system relies on the photosensitizer and their photophysical properties. The highly reactive oxygen species (ROS) such as singlet oxygen ($^1O_2$) and free radicals, induced oxidative damage on biomolecules, enhance lipid peroxidation, and disrupt the tumor microenvironment; thereby, resulting in cellular oxidative injury, induce mutations, necrosis, and/or apoptosis, etc. There are many reports on development of novel efficient photostable Os(II)-complexes for the PDT. Zhang and Huang (2018) explored the efficacy of three osmium terpyridiyl complexes as photosensitizes, exhibiting obvious metal-to-ligand charge transfer (MLCT) with absorption at 476, 481 and 492 nm as well as a weak singlet ground state to triplet metal to ligand charge transfer absorption band centered in the NIR region (650–775 nm). These complexes exhibit dual emissions in both; visible and NIR regions with the maximum wavelengths around 583/702, 588/709, and 583/719 nm, respectively with a life time around 90–120 ns (Wehlin et al., 2020). Recently, Roque et al. (2020) demonstrated Os(II)-oligothienyl complexes as a hypoxia-active photosensitizer for PDT. A series of Os(II)-oligothienyl polypyridyl complexes were prepared as shown in Fig. 7.38.

The absorption and emission spectra of the Os(II)-complex is shown in Fig. 7.39. The spectra put forward three important features: (i) Pair of absorption bands between 400 and 500 nm and a much broader and weaker band extending beyond 700 nm, which is due to the Os(dπ)→ LL(π^*) MLCT transitions for LL = bpy and dmb, with the lower-energy transition being

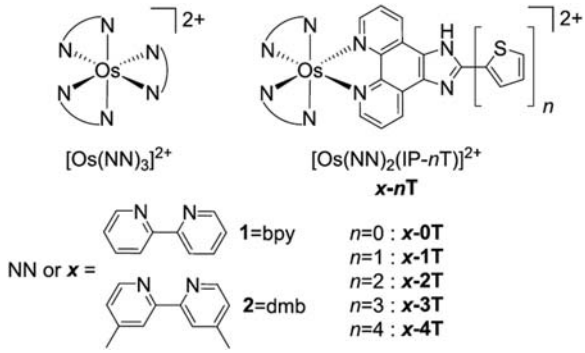

FIG. 7.38 A series of Os(II)-oligothienyl polypyridyl complexes. *Adapted from Roque III, J.A., Barrett, P.C., Cole, H.D., Lifshits, L.M., Bradner, E., Shi, G., 2020. Os(II)-Oligothienyl complexes as a hypoxia-active photosensitizer class for photodynamic therapy. Inorg. Chem. 59 (22), 16341−16360. With permission.*

associated with a formally spin-forbidden absorption to the triplet state, (ii) An intense peak around 290 nm correspond to the intra ligand (IL) ($^1\pi\pi^*$) transition localized on the ancillary LL (bpy/dmb) ligands and were also largely unaffected by the presence of imidazo[4,5-f][1,10]-phenanthroline-oligothiophene ligands, and (iii) A peak that appeared in the 300−500 nm window, only for complexes with thiophene units. This peak increases its intensity and decreases in energy as the number of conjugated thiophene rings increases and therefore, assigned to the thienyl-localized IL ($^1\pi\pi^*$) transition of the IP-nT ligand, which is ^{1}ILCT for $n \geq 2$.

These complexes exhibit an emission profile with $^{em}\lambda_{max}$ between 745 and 770 nm for the bpy series and between 768 and 774 nm for the dmb series. The spectra were broad, featureless, shifting to slightly red shifted with the increase in degree of conjugation. The excitation maxima did not vary significantly within or between families ($\sim$470 nm) and were the same as observed previously for phenanthroline-based Os(II)-complexes. This indicates that the emission arises predominantly from the ^{3}MLCT state. The oligothiophene complexes 1−4T and 2−4T had singlet oxygen quantum yields of 70% and 56%, respectively, which were related to their microsecond ^{3}ILCT life times. It was concluded that a ^{3}ILCT of sufficiently low energy relative to the ^{3}MLCT state, which is an essential condition for the effective singlet oxygen sensitization. The dominant and highly photosensitizing ^{3}ILCT state in 1−4T and 2−4T was responsible for the activity against SK-MEL-28 cancerous cells under both; normoxic and hypoxic conditions.

7.4.5 Photochemistry and applications of osmium complexes

Osmium complexes have been designed as photocatalyst for organic conversion like amines to imines, carbonates to formaldehyde, etc. and in photoredox

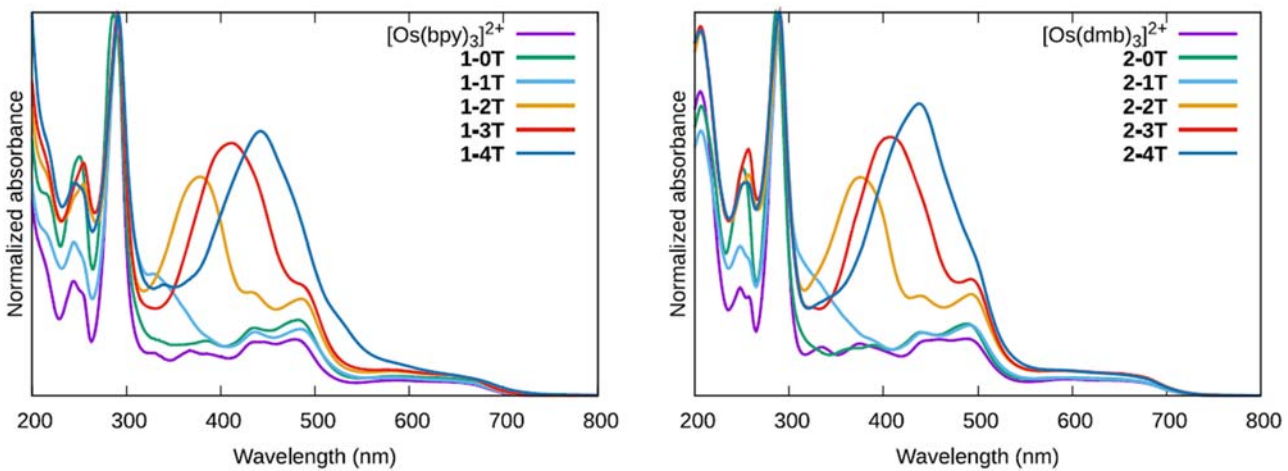

FIG. 7.39 Normalized absorption and emission spectra of Os(II)-oligothienyl polypyridyl complexes. *Adapted from Roque III, J.A., Barrett, P.C., Cole, H.D., Lifshits, L.M., Bradner, E., Shi, G., 2020. Os (II) Oligothienyl complexes as a hypoxia-active photosensitizer class for photodynamic therapy. Inorg. Chem. 59 (22), 16341−16360. With permission.*

reaction such as photocatalytic generation of hydrogen, and hydrohalic acid splitting, etc. Li et al. (2016) developed triazole based Os(II)-complexes for light driven anaerobic oxidation of amines to imines, the complexes $[Os(fptz)_2(PPhMe_2)_2]$ (where, fptzH = 3-trifluoromethyl-5-pyridyl-1,2,4-triazole), $[Os(fptz)_2(CO)\ (L1)]$ (where, L1 = PPh_3; or = pyridine) have been used successfully as photocatalyst for the oxidation of amine to imine by using molecular oxygen as green oxidant. The photocatalytic activity of the $[Os(fptz)_2(PPhMe_2)_2]$ was much higher than that of the other reported Os(II)-complexes. This enhanced activity can be attributed to its ability to produce singlet oxygen, which was responsible for the oxidation of amine to imine. This activity was due to strong absorption of visible light at 410 nm and weak absorption bands centered around 460 and 550 nm and the long-lived triplet state of $[Os(fptz)_2(PPhMe_2)_2]$. The emission band was around 643 nm originating from the ^{3}MLCT [Os(dπ) → fptz (π*)] excited state. This result was confirmed by DFT/TD-DFT calculations.

Miyake al. (2009) prepared a series of Os(II)-complexes and used for photocatalytic production of dihydrogen. This group developed diphosphine ligand bearing Os(II) bis(terpyridyl) complexes for light harvesting in the production of dihydrogen (Fig. 7.40).

The Os(II)-terpyridyl complex with diphosphine moiety was synthesized and combined with $[RhCl(CO)_2]_2$ to form a dinuclear Os−Rh complex (Fig. 7.41). These complexes exhibit two similar visible absorption bands around 483 and 655 nm, which were due to the ^{1}MLCT and ^{3}MLCT, respectively. The emission maximum of the Os−Rh complex was observed around 727 nm. The complex was found to be an effective photocatalyst for the production of dihydrogen and, a plausible mechanism was proposed (Fig. 7.42). The Os−Rh complex A is photoexcited at above 380 nm, the quenching of A* at the coordinated rhodium center and by sodium ascorbate (NaHA) proceeds smoothly to cause one electron reduction of the rhodium center via intramolecular electron transfer, followed by sequential second electron reduction of the rhodium center to form the reduced rhodium species B. Reaction of B with a proton generates the rhodium hydride species C, which turns into dihydrogen and the rhodium species A by protonolysis. Vogler (2016) reported the photochemistry of osmium complex $[Os(bipy)_2(CO_3)]$ and phororeduction of carbonate to formaldehyde. The complex undergoes a photoredox reaction to form $[Os(VI)\ (bipy)_2(O)_2]^{2+}$ and formaldehyde.

In recent times, although water splitting with hydrogen generation has attracted much attention, yet another promising focus is on hydrohalic acid (HX) splitting, Wehlin et al. (2020) used osmium-complexes for photocatalytic splitting of hydrohalic acid. Two osmium(II)- photocatalysts bearing a dicationic 4,4′-bis-(trimethylaminomethyl)-2,2′-bipyridine (tmam) ligand and 2,2′-bipyridine $[Os(bpy)_2(tmam)]^{4+}$ or 4,4′−$(CF_3)_2$−2,2′-bipyridine $[Os((CF_3)_2bpy)_2(tmam)]^{4+}$ ancillary ligands were prepared and used for HX splitting.

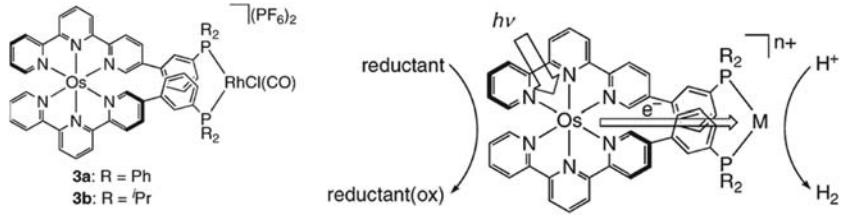

FIG. 7.40 Design of diphosphine ligands bearing$Os(tpy)_22^+$ as a light-harvesting unit. *Adapted from Miyake, Y., Nakajima, K., Sasaki, K., Saito, R., Nakanishi, H., Nishibayashi, Y., 2009. Design and synthesis of diphosphine ligands bearing an osmium (II) bis (terpyridyl) moiety as a light-harvesting unit: application to photocatalytic production of dihydrogen. Organometallics 28 (17), 5240–5243. With permission.*

Fig. 7.42 represents the absorption and emission properties of osmium complexes. Visible light excitation of both complexes exhibited a photo-luminescence (PL) centered at 815 and 775 nm for Os-bpyand Os-CF_3, respectively. The electron withdrawing nature of the trifluromethyl moiety resulted in a 40 nm hypsochromic shift in the emission maximum compared to unsubstituted Os-bpy complex. The photocatalyst $[Os(bpy)_2(tmam)]^{4+}$was found to be inefficient in iodide oxidation. In contrast, visible light excitation of $[Os((CF_3)_2bpy)_2(tmam)]^{4+}$ led to rapid iodide oxidation ($k_q = 2.8 \times 10^{11}\ M^{-1}\ s^{-1}$). The data revealed that Os(II)-photocatalysts can be finely tuned for its application in HX splitting.

Osmium complexes offer a wide range utility in the field of OLEDs, solar energy, diagnosis, therapeutic, and light driven organic reactions. The choice of osmium complexes over other analogs is due to their remarkable photo-physical properties, which can be tuned strategically by designing the ligands, and its chemical architecture.

7.5 Summary

In summary, the recent development of the photophysics and photochemistry of coordination of compounds of Fe, Ru, and Os complexes demonstrated that there is excellent visible light absorption and long-lived excited state with efficient intersystem crossing process. The understanding of the photophysical properties of transition metal complexes, in particular, the role of excited states, provides insight into the design of transition metal complexes for the application in photodynamic therapy, solar energy conversion and photocatalysis. The development of sustainable, eco-friendly, and industrially useful transition metal complexes will be promising in the future.

Chapter 8

Complexes of cobalt, rhodium and iridium

Simran Sharma, Priya Sahni, Rahat Gupta, Anindya Roy and Amlan K. Pal

Department of Chemistry, Indian Institute of Technology Jammu, Jammu and Kashmir, India

8.1 Introduction

Group 9 of the periodic table constitutes transition elements cobalt ($^{58}Co_{27}$), rhodium ($^{103}Rh_{45}$) and iridium ($^{192}Ir_{77}$) exhibiting the most common oxidation states of +2 and +3 and having nine valence electrons with a general electronic configuration of $(n-1)d^74s^2$. The elements of this group are hard, shiny and silvery-white in appearance. In the earth's crust cobalt accounts for 25 ppm only and is the least abundant metal in the first row of the transition elements, whereas the abundance of rhodium and iridium are even daunting with a value of 0.0001−0.001 ppm only (Lide, 2004). In the early decades, only a handful number of reports were available for the photochemistry of these elements but recently the literature has seen tremendous growth in the research area of the photochemistry and photophysics of group 9 complexes, in particular complexes of 3d transition-metals (Hefffern et al., 2013). In general, group 9 elements find a diverse set of applications, e.g., cobalt shows a wide range of applications in lithium-ion batteries, alloys, catalysts, etc (Yang et al., 2013). Vitamin B_{12} is the only organometallic complex in nature comprising Co(II) (Schrauzer, 1968). Rhodium shows applications in ornamental decorations, electronics, as nuclear fuels and also in the glass industry. Rhodium is also used as a catalyst, one of the common examples is Wilkinson's catalyst $[Rh(Cl)(PPh_3)_3]$, used for the hydrogenation of the unsaturated olefins (Perea-Buceta et al., 2015). Iridium displays its applications in different sectors of industrial and medicinal chemistries (Ho et al., 2020). Iridium is also used as a catalyst, the well-known example is Vaska's complex (Matheau-Raven et al., 2020). Another example is the Cativa process, which involves the use of an iridium complex for the carbonylation of methanol (Sunley and Watson, 2000). In this chapter, published works on the synthesis, photochemistry and photophysics of group 9 (Co, Rh, Ir) complexes that appeared

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00004-6

over the past few decades have been reviewed. Applications in the fields of photoredox catalysis, metal-sensing, solid-state lighting devices (OLEDs and LECs) of group 9 complexes have also been discussed. The discussions of the photophysical properties of the group 9 complexes will be considered by tuning the these properties of the complexes behaving as phosphorescence emitters. In this respect, some commonly used ligands in the synthesis of group 9 complexes are shown in Fig. 8.1.

The splitting of d-orbitals in the Co, Rh and Ir metal ions in an octahedral ligand field is shown in Fig. 8.2A. The complexes show different natures of the origin of luminescence, e.g., ^{3}MLCT, ^{3}LMCT, ^{3}ILCT and ^{3}LC. In general, MLCT is the metal-to-ligand charge transfer transition that takes place from the molecular orbital (M O). Of the metal to the ligand orbital whereas LMCT is the ligand-to-metalcharge transfer, i.e., transfer of electrons from the M O of ligand to the metal (Verhoeven, 1996). MC and LC states are originated from the metal-centered d $\rightarrow$ d transitions and $\pi \rightarrow \pi^*$ and/or n $\rightarrow \pi^*$ ligand centered transitions, respectively. LLCT corresponds to the transfer of an electron from one ligand to other within the complex (Fig. 8.2B and C). The origin of transition depends on the spatial distributions of the outershell orbitals of the group 9 elements. The 3d(Co), 4d(Rh) and 5d(Ir) orbitals have different spatial extensions; the effect of destabilization and splitting is minimum for the 3d orbital in an octahedral ligand field. The amount of ligand field splitting (Δ_{oct}) depends on the field strength exerted by the ligands, as arranged in the spectrochemical series (Ryutaro, 1938). In an octahedral field, Δ_{oct} is small for Co(II), because of which the lowest-excited state for Co(II)-polypyridyl complexes mostly show non-emissive nature but in association with specially designed ligands, these complexes show ^{3}LMCT, ^{3}MLCT and ^{3}ILCT nature too. In Rh(II)-polypyridyl complexes, as the Rh(II) 4d orbitals display intermediate values of Δ_{oct} of Co(II) and Ir(II), the MC levels show some contribution in the deactivation of the MLCT levels, which are normally emissive at 2.10−2.88 eV. On the another hand, for Ir(III)-polypyridyl complexes, the values of Δ_{oct} are very large due to which ^{3}MC levels are high in energy that they do not usually affect the emissive ^{3}LC and ^{3}MLCT states (2.10−3.00 eV) (Balzani and Campagna, 2007).

8.2 Luminescent Co(II/III) complexes

8.2.1 Photophysical properties of polyhetrocyclic and polypyridyl Co(II/III) complexes

The first luminescent Co(III) complex, $K_3[Co(CN)_6]$, **(1)**, was reported by Porter and Mingardi (1966). A broad and structureless emission band centered at 704 nm was observed for $K_3[Co(CN)_6]$ with a fullwidth at halfmaximum (FWHM) of $\sim$2000 cm^{-1}. This band was assigned as $^3T_{1g} \rightarrow {}^1A_{1g}$(Oh) phosphorescence based on band position and lifetime ($\tau_{PL} = 10^{-3}$ s). Later,

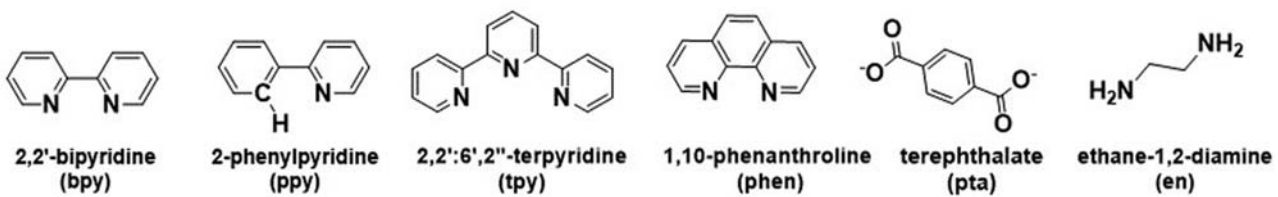

FIG. 8.1 Benchmark ligands used in the synthesis of the complexes of group 9 elements.

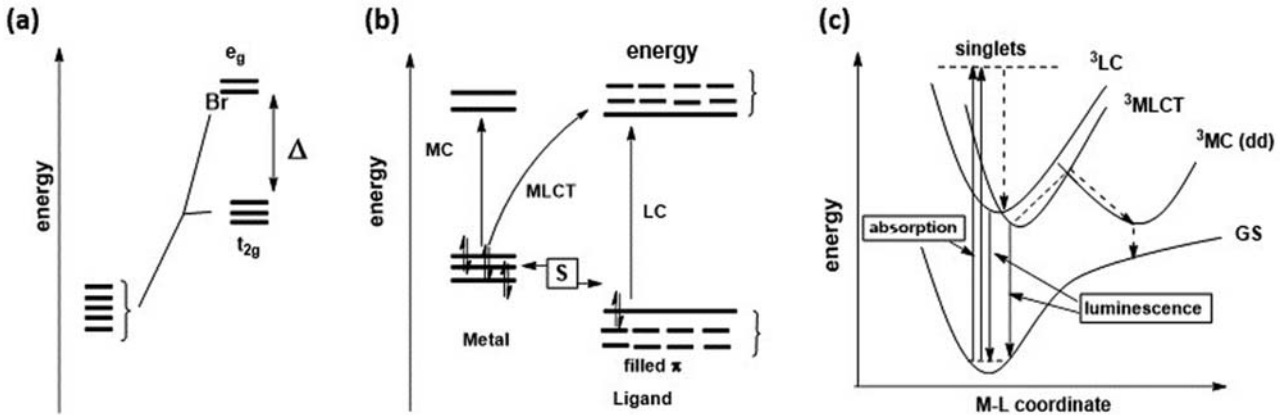

FIG. 8.2 (A) d-orbitals splitting in an octahedral field; (B) the orbital description of MC, MLCT and LC transitions; (S = EWG, resulting in stabilization or destabilization) and (C) electronic transitions involving MC, MLCT and LC excited states (MC states are not emissive).

Zuloaga and Kasha (1968) reported another example of luminescent Co(III) complex, *trans*-$Na_5[Co(CN)_4(SO_3)_2]$, **(2)**. This complex exhibited a broad and structureless luminescence spectrum centered at 699 -nm at 77 K and the luminescence was assigned as $^3T_{1g} \rightarrow {}^1A_{1g}$(Oh) phosphorescence. Yusuke (1979) also reported some examples of luminescent Co(III) complexes, namely, *cis*-$K_3Na_2[Co(CN)_4(SO_3)_2]$, **(3)**, $M_3[Co(CN)_6]$, **(4)**, (M = K **(4A)**, Rb **(4B)**, Cs **(4C)**) and *trans*-$Na_5[Co(CN)_4(SO_3)_2]$, **(2)**. Luminescence spectrum of *cis*-$K_3Na_2[Co(CN)_4(SO_3)_2]$, **(3)**, at 20 K, exhibited a broad and structureless band at 757 nm and a FWHM of 2000 cm^{-1} when excited at 365 nm. Luminescence spectra of $M_3[Co(CN)_6]$, **(4)**, (M = K, Rb, Cs) excited at 313 nm measured on a single crystal at 20 and 77 K, exhibited a peak position of 704−709 nm. The FWHM was found to be about 2600 cm^{-1} for $K_3[Co(CN)]_6$. Luminescence spectrum of *trans*-$Na_5[Co(CN)_4(SO_3)_2]$, **(2)**, excited at 365 nm exhibited a broad and structureless band at 704 nm with FWHM about 2300 cm^{-1}, which was found to be close to the observation of Zuloaga and Kasha (1968). Muto et al. (1979) synthesized a novel Co(II) complex, $Co(koj)_2 \cdot H_2O$, **(5)**, (Hkoj = kojic acid, 5-hydroxy-2-(hydroxymethyl)-4*H*-pyran-4-one) by adding the $Co(OH)_3$ to a kojic acid suspension, in which the kojate ions were found to be coordinated to the metal as bidentate ligands. It exhibited a green luminescence at 500 nm in aqueous, acidic solutions and even in the solid-state upon excitation at 365 nm.

Zhang et al. (2002) reported two Co(III)-polypyridyl complexes, $[Co(phen)_2HPIP]^{3+}$, **(6)**, (HPIP = 2-(2-hydroxyphenyl)imidazo[4,5-f][1,10] phenanthroline, phen = 1,10-phenanthroline) and $[Co(phen)_2HNAIP]^{3+}$, **(7)**, (HNAIP = 2-(2-hydroxy-l-naphthyl)imidazo[4,5-f][1,10]phenanthroline) to study the effect of intramolecular hydrogen bond on the DNA-binding and photocleavage properties of polypyridyl Co(III) complexes. The complexes were synthesized by refluxing *cis*-$[Co(phen)_2Cl_2]Cl \cdot 3H_2O$ and HPIP or HNAIP in EtOH in good yields of 72%−78%. The luminescence nature of these complexes **(6)** and **(7)** was used in the detection of CT DNA, where both the complexes exhibited enhancement in luminescence intensity ~350 nm in aqueous buffer (20 μM [Co], 5 mM Tris, 50 mM NaCl, pH 7.2, λ_{irr} = 300 nm) at 298 K. The effect was found to be more pronounced for complex **(6)** as this intercalated into the hydrophobic environment of the DNA helix and thus, the collision and energy dissipation with the environmental water and oxygen was found to be lower. Thus, complex **(6)** displayed stronger binding affinity whereas **(7)** exhibited partial intercalation.

A three-dimensional polymeric cobalt compound $[Co(DCNT)(H_2O)]_n$, **(8)**, (H_2DCNT = 2,4-bis(4-carboxyphenylamino)-6-diethylamino-1,3,5-triazine) was synthesized by Wei and Wu (2007) by the hydrothermal reactions of $Co(NO_3)_2 \cdot 6H_2O$ and H_2DCNT. In the polymer, each $[DCNT]^{2-}$ possessed three coordination sites, one nitrogen atom in the triazine ring coordinating to Co(II) and two carboxylates adopting μ_2-bridging mode, which made the infinite Co(II) chains array uniform and even towards the crystallographic

c-axis. The emission spectrum exhibited a maximum peak at 410 nm and a shoulder peak at 374 nm. The peak at 374 and 410 nm was assigned to ^{3}ILCT (triplet intraligand charge transfer) and ^{3}LMCT (triplet ligand-to-metal charge transfer), respectively. The ^{3}ILCT resembled the ligand-centered transitions observed in the ligand H_2DCNT and the triazine ring, one nitrogen atom coordinated to Co(II), which favored the ^{3}LMCT from the diethylamino donor group along the aromatic triazine ring to Co(II).

Anbalagan and Ganeshraja (2013) explored the luminescent complexes as *cis*-$[Co^{III}(en)_2(RNH_2)Cl]Cl_2$, **(9)**, with R = Hex^n **(9A)**, Pen^n **(9B)**, Bui **(9C)**, Bu^n **(9D)**, Pr^n **(9E)**, Et **(9F)**, Me **(9G)** and Bz^n **(9H)** complexes exhibiting ferromagnetism. The complexes displayed emission, $\lambda_{em} \sim 411$ nm upon excitation at 360 nm, with associated excited-state lifetime (τ_{PL}) values of $\tau_1 = 3.9-3.1$, $\tau_2 = 12.3-9.5$, $\tau_3 = 0.7-0.9$ ns in fluid solutions (water and mixture of water:^{i}PrOH (70:30, w/w)) and the emission was attributed to the ^{3}LMCT transition. Despite different geometries and ligand environments, the excitation spectra of these complexes closely resembled the peak profiles. The d → d absorption features of these complexes at 362−366 nm were assigned to spin-allowed $^1A_1 \rightarrow {}^1T_{2g}$ transition, mixed with some extent of ^{3}LMCT [π^*(N) → dπ(Co)]. Thus, it was suggested that the emissions were an admixture of ^{3}LMCT + ^{3}LC transitions. The emission intensities of the complexes followed the order:

(9A) > **(9B)** > **(9C)** > **(9D)** > **(9E)** > **(9F)** > **(9G)** due to the higher electron donation of the hexyl group compared to that of the methyl group. The multi-exponential decay was explained on the basis of (i) different electronic coupling strengths existing in the complexes due to the varied electron donations of the coordinating ligands and (ii) fast and slow components due to the thermally equilibrated emitting states. The enhancement of lifetime from **(9A)** ($\tau_2 = 9.5$ ns) to **(9G)** ($\tau_2 = 12.3$ ns) may be attributed to (i) accumulation of higher negative charge in complex **(9A)** compared to that in **(9G)**, leading to destabilization of the emitting (d → d) + LMCT state, (ii) lower HOMO-LUMO gap in **(9A)** compared to that in **(9G)** due to the e^- delocalization in the long C_6 alkyl chain and (iii) pronounced radiationless decay in **(9A)** due to the vibrational coupling of the long C_6 alkyl chain (Xue et al., 2010). On the other hand, hydrophobicity, the rigidity of the coordination environment and the hydrogen bond donor/acceptor abilities of the solvent molecules may also alter the emissive behavior.

Two novel Co(III) complexes $[Co(phen)_2(bbenzimH_2)](ClO_4)_3$, **(10)** and $[Co(bpy)_2(bbenzimH_2)](ClO_4)_3$, **(11)**, (bbenzim$H_2$ = bibenzimidazole and bpy = 2,2′-bipyridine) were synthesized (Indumathy et al., 2014). The complexes **(10)** and **(11)** were synthesized by refluxing the precursor complex $[Co(phen)_2Cl_2]Cl$ or $[Co(bpy)_2Cl_2]Cl$ and $[Ag(bbenzimH_2)]NO_3$ in methanol with good yields of ∼ 87%. Complex **(11)** exhibited an emission band at 402 nm, upon excitation at 280 nm. Anion sensing studies of the complex **(11)** with different biologically important anions like F^-, Br^-, I^-, ClO_4^-, OH^-,

OAc^- were carried out using various methods such as fluorescence spectroscopy. The addition of Br^- and ClO_4^- anions caused a slight decrease in the intensity of the emission spectra of the complex **(11)**. The emission intensity of complex **(11)** was completely quenched on the addition of tetrabutylammonium (TBA) salts of F^-, I^-, OH^- and OAc^-. The complete quenching for F^-, OH^- and OAc^- was due to the hydrogen bonding ability and high basicity of these anions, whereas for I^-, which lacks in both these properties, the quenching of fluorescence was tentatively assigned to the heavy atom effect *via* formation of a charge-transfer complex (Watkins, 1974). Similar effects were reported for TBAI salt and metal iodides in carbazole-based conjugated co-polymers and benzimidazole-based tripodal receptors (Vetrichelvan et al., 2006; Lee et al., 2011).

Li et al. (2015) investigated three coordination polymers of cobalt, e.g.,$\{[Co(4pmntd)_2(CF_3SO_3)(H_2O)]\cdot(CF_3SO_3)\cdot(C_2H_5OH)\cdot 0.5(CHCl_3)\cdot H_2O\}_n$, **(12)**, $\{[Co(4\text{-}pmntd)(H_2O)_4]\cdot(NO_3)_2\cdot H_2O\}_n$, **(13)** and $\{[Co(4pmntd)(pta)(CH_3OH)_2]\cdot 2(CHCl_3)\}_n$, **(14)**, (4-pmntd = *N,N′*-bis(4-pyridylmethyl)-naphthalene diimide; pta = terephthalate). The polymers were synthesized by the reactions of 4-pmntd with $Co(CF_3SO_3)_2\cdot 4H_2O$, $Co(NO_3)_2\cdot 6H_2O$ and Co(pta) to yield **(12)**, **(13)** and **(14)**, respectively, in poor yields of 11%−25%. The emission spectra of complexes **(12−14)**, $\lambda_{em} = 420$ nm upon excitation at 320 nm resembled that of the free 4-pmntd ligand, excluding peak positions and the emission intensity. The emission intensity of complex **(13)** increased gradually upon the addition of two equivalents of acetate into the DMF solution of complex **(13)**, whereas, anions like F^-, Cl^-, Br^-, I^-, N^{3-}, SCN^- and Ox^{2-} (Ox^{2-} = oxalate^{2-}) led to a decrease in the emission intensity. The variation was speculated to occur due to the coordinating nature of the OAc^- anions to the Co(II) ion in **(13)**. This coordination was further supported by M06L/DZP level calculations as well as polarizable continuum models in DMF solution that indicated the easy dissociation of the monodentate pyridine substituted ligands.

A novel dicubane Co(III)/Co(II) complex for applications in optoelectronics, namely $[Co^{II}_2Co^{III}_2(HPN)_4(H_2O)_2(CH_3COO)_2]\cdot 4H_2O$, **(15)**, ($H_2HPN$ = [1-(3-hydroxypropyliminomethyl)naphthalene-2-ol) was synthesized by Coban et al. (2018). Complex **(15)** was synthesized by mixing the hot alcoholic solutions of $Co(CH_3COO)_2\cdot 4H_2O$ and the ligand in a good yield of 75%. The complex was characterized by elemental analysis, FT-IR, solid-state UV-vis absorption spectroscopy and single-crystal X-ray diffraction (XRD). The XRD studies showed a cationic tetrameric arrangement consisting of a defected dicubane core with two missing vertexes. Each cobalt ion has a distorted octahedral geometry with six-coordinations. At room temperature (RT), the free ligand H_2HPN displayed a strong blue emission band at $\lambda_{em} = 482$ nm ($\lambda_{exc} = 349$ nm) which was tentatively assigned to the $n \rightarrow \pi$ or $\pi \rightarrow \pi^*$ electronic transitions (^{3}ILCT), while complex **(15)** exhibited two emission bands at $\lambda_{em} = 469$

and 682 nm, respectively ($\lambda_{exc} = 349$ nm) (Kocak et al., 2017; Oylumluoglu et al., 2017). The enhancement of luminescence in complex **(15)** was tentatively attributed to the chelation of the ligand to the metal center, which enhanced the "rigidity" of the ligand and reduced the energy loss *via* a radiationless pathway (Oylumluoglu et al., 2017; Feng et al., 2015). The emissions of the complex were tentatively assigned to the $n \rightarrow \pi$ or $\pi \rightarrow \pi^*$ type intraligand fluorescence as similar emission was also observed for the free ligand H_2HPN.

Two emissive Co(II) complexes **(16)** and **(17)** with redox-active anthraquinone-type ligand, 2-(2-pyridyl)-1*H*-anthra[1,2-*d*]imidazole-6,11-dione (abbreviated as PyAnIm) were also reported (Shiga et al., 2018). The ligand PyAnIm adopted tridentate and bidentate chelating modes to give rise to the complexes $[Co^{II}(PyAnIm)_2].n(solv.)$, **(16)** and $[Co^{III}(PyAnIm)_3]$, **(17)**, respectively. Trimethylamine and PyAnIm in acetonitrile were added in the solution of $Co(BF_4)_2 \cdot 6H_2O$ to synthesize **(16)** and **(17)**. The stirring was done for 5 min and L-ascorbic acid in methanol was added to it. The resulting solution was filtered and allowed to stand, yielding dark brown blocks of **(16)** in a poor yield of 14%. If **(16)** was left to stand for several days, it resulted in yielding red crystals of **(17)** in a very poor yield of 0.02%. The ligand PyAnIm exhibited a ^{1}ILCT absorption at 395 nm and a broad ^{3}ILCT fluorescence at 519 nm with a quantum yield of 0.95%. Complex **(16)** exhibited a weaker emission at ~ 510 nm while **(17)** displayed a stronger emission at ~ 560 nm. The weak emission of **(16)** was tentatively due to the paramagnetic quenching of the unpaired e^- from the Co(II) center and the effect of dissociation equilibrium of the complex. On the contrary, the bathochromic shift of the emission band of **(17)** relative to that of **(16)** was caused by the decrease in LUMO energy, which was affected by the charge and acidity of the coordinated metal ion.

Özbek et al. (2019) synthesized a Co(II) complex, $[Co^{II}(3\text{-fba})_2(na)_2(H_2O)_2]$, **(18)**, (where 3-fba = 3-fluorobenzoate and na = pyridine-3-carboxamide or nicotinamide) with a yield of 67% by mixing a solution of sodium 3-fluorobenzoate in water to a mixture containing $CoSO_4 \cdot 7H_2O$ and pyridine-3-carboxamide in water. Complex **(18)** was characterized by the single-crystal XRD studies that revealed the distorted octahedral geometry of the metal ion with an N_2O_4 bonding set of atoms around the metal center. The Co-O and Co-N bond lengths lie in the range of 2.07−2.17 Å and the bond angles around the Co(II) cation lie in the range of 88 to 180 degrees. The UV-vis absorption spectrum of complex **(18)** in DMSO exhibited a sharp band at 365 nm and a shoulder at 501 nm, which were tentatively assigned to a mixture of $n \rightarrow \sigma^*$, $n \rightarrow \pi^*$ and $\pi \rightarrow \pi^*$ transitions and a singlet ligand-to-metal charge transfer (^{1}LMCT) transition, respectively. The HOMO-LUMO band gap – was found to be 3.50 eV. The fluorescence emission spectrum of complex **(18)** displayed a peak at 370 nm, albeit with a weak emission intensity and a shoulder at 465 nm in DMSO solution. The peaks were assigned

as ligand-centered emissions due to the difference in electron density in the ligands.

Sathiyakumar et al. (2020) explored two novel Co(II) complexes, [Co(2-PYMC)$(NO_3)(H_2O)_2]\cdot NO_3$, **(19)**, (where, 2-PYMC = methyl-2-(pyridine-2-yl-methylene)hydrazinecarboxylate) and [Co(2-PYEC)$(NO_3)(H_2O)_2]\cdot NO_3$, **(20)**, (2-PYEC = ethyl-2-(pyridine-2-yl-methylene)hydrazinecarboxylate) by using a solvent-free mechano-chemical method. Equimolar mixtures of $Co(NO_3)_2\cdot 6H_2O$ and 2-PYMC or 2-PYEC by mechanochemical mixing afforded the complexes **(19)** and **(20)** in good yields (73%−82%). These complexes were characterized by elemental analysis, single-crystal XRD, UV-vis, IR and photoluminescence measurements. In the UV-vis absorption spectroscopy, the cobalt complexes exhibited λ_{max} values at 540 and 535 nm for **(19)** and **(20)**, respectively, which were tentatively assigned to a $^4T_{1g}(F) \rightarrow {}^4T_{1g}(P)$ transition (Newkome et al., 1984). The broad shoulder at 350 nm was tentatively assigned to either a charge transfer or a d → d transition (Ivanovic-Burmazovic and Jelkovic, 2004). The emission spectra of the free ligands were recorded in the solid-state ($\lambda_{exc} = 300$ nm) at RT. The ligand, 2-PYMC exhibited two intense bands at 348 and 351 nm whereas, four peaks at 355, 401, 457 and 527 nm were observed for 2-PYEC. The complex **(19)** exhibited multiple emission peaks between 430 and 450 nm upon excitation at 280 nm, whereas **(20)** showed a broad emission with $\lambda_{em} = 428$ nm.

Recently, four mononuclear luminescent Co(II)-Schiff base complexes with substituted hydrazinoquinoline Schiff bases, Ar-2-(salicylidene hydrazino)quinoline, [Ar = 4-methyl **(21)**, Ar = 4,6-dimethyl **(22)**, Ar = 4-methyl-6-chloro **(23)**, Ar = 4-methyl-6-methoxy **(24)**] were reported by Priyadarshini and Selvi (2021). The ligands were synthesized by simple condensation of hydrazones with salicylaldehyde in a 1:1 M ratio. An equimolar mixture of the ligands to an ethanolic solution of $CoCl_2\cdot 6H_2O$ afforded the complexes **(21−24)** with 50%−80% yield. The complexes were characterized by various analytical techniques, e.g., UV-vis, IR, NMR and TGA. The Co(II) ion was found to occupy a distorted octahedral geometry with the ligands coordinating through NˆNˆO tridentate fashion. In the emission study complexes **(21−24)** exhibited blue luminescence at 435−465 nm in MeCN. The complex **(23)** exhibited high luminescence intensity; the blue-shifted emission ($\lambda_{em} = 435$ nm) of this complex was due to the presence of electron-withdrawing substituents, which led to a stronger interaction with the metal center in the excited state. The sharp and intense nature of the luminescence peak of **(23)** was concluded to be originated from ^{3}MLCT transitions.

8.2.2 Photoredox catalysis of Co(III)-guanidyl complexes

Two rare examples of photoactive Co(III) complexes, $[Co(dgpy)_2][(BF_4)_3]$, **(25)** and $[Co(dgpz)_2][(BF_4)_3]$, **(26)**, (dgpy = diguanidylpyridine and dgpz = diguanidylpyrazine) were also reported exhibiting deep blue luminescence at RT

(Fig. 8.3). These complexes were found to be attractive alternatives to the traditional photocatalysts based on Ru(II) and Ir(II) (Pal et al., 2018b). The electron-rich ligands e.g., dgpy and dgpz capable of forming six-membered chelate rings and containing a strongly σ-donating hpp moiety (hpp = 1,3,4,6,7,8-hexahydropyrimido[1,2-a]pyrimidine, also abbreviated as guanidyl here) were used to synthesize the complexes **(25)** and **(26)** (Fig. 8.3) (Pal et al., 2014; Pal and Hanan, 2014). The reactions of dgpy and dgpz with $[Co(OH_2)_6][(BF_4)_2]$ in 2.2:1 stoichiometry afforded the complexes $[Co(dgpy)_2][(BF_4)_3]$, **(25)** and $[Co(dgpz)_2][(BF_4)_3]$, **(26)** in 52%−61% yields. Complexes **(25)** and **(26)** exhibited an irreversible oxidation at 1.75 and 1.98 V *vs* SCE, with associated quasi-reversible reductions at −0.58 ($E_{LUMO} = -2.51$ eV) and −0.39 ($E_{LUMO} = -2.73$ eV) *vs* SCE, respectively. The oxidation process was based on the electron rich ligand systems for both the complexes whereas for complexes **(25)** and **(26)**, the reductions were assigned to be based on the Co(III) ion and the Co(III) + pyrazine moieties, respectively, as suggested by the DFT calculations. The higher energy calculated for the HOMO of **(25)** ($E_{HOMO} = -6.49$ eV) compared to that of **(26)** ($E_{HOMO} = -6.75$ eV) confirmed the relative electron-poor nature of dgpz as compared to dgpy. The UV-visible absorption spectra of **(25)** and **(26)** displayed ligand-centered (LC) $\pi \rightarrow \pi^*$ transitions around 220−330 nm in MeCN solutions. The low-energy bands of **(25)** and **(26)** appearing at $\lambda_{abs} = 345-402$ nm were assigned as a mixture of ligand-to-metal and ligand-to-ligand charge transfer transitions (^{1}LMCT + ^{1}LLCT). Complexes **(25)** and **(26)** in degassed MeCN exhibited emission maxima at 440 and 412 nm, respectively. The photoluminescence quantum yields (Φ_{PL}) were found to be 0.70% and 0.40% for **(25)** and **(26)**, respectively, in degassed MeCN at RT, while in aerated MeCN the Φ_{PL} values of **(25)** and **(26)** were reduced to 0.40% and 0.12%, respectively. Complex **(25)** displayed monoexponential emission decay with an associated excited-state lifetime (τ_{PL}) of 5.07 ns in degassed MeCN at RT, whereas **(26)** exhibited a biexponential decay of 3.21 and 8.69 ns (Fig. 8.3). In comparison to an isoelectronic Fe^{II}−NHC (NHC = *N*-heterocyclic carbene) complex ($E_{T1} = 1240$ nm, $\tau_{PL} = 528$ ps) the τ_{PL} values of **(25)** and **(26)** were found to be about 950 times higher, presumably due to the very low energy of the triplet state in the iron complex (Chábera et al., 2018). The excited-state oxidation (E_{Ox}*) and reduction potentials (E_{Red}*) were calculated as −1.26 and −1.15 V for **(25)** and −2.26 and 2.75 V for **(26)** *vs* SCE. These complexes showed significantly higher E_{Red}* values compared to the $[Ru(bpy)_3]^{2+}$ (E_{Red}* = 0.77 V), $[Ir(dF(CF_3)ppy)_2(dtbubpy)]^+$, (dF-($CF_3$)ppy = 2-(2,4-difluorophenyl)-5-(trifluoromethyl) pyridinato-C^2,N′) (E_{Red}* = 0.89 V), $[Cr(Ph_2phen)_3]^{3+}$, (Ph_2phen = 4,7-diphenyl-1,10-phenanthroline) (E_{Red}* = 1.40 V), triphenylpyrylium (E_{Red}* = 2.30 V) and mesityl diaminoacridinium (E_{Red}* = 1.25 V) and were reported to be the strongest photo-oxidant to-date (Pal et al., 2018b).

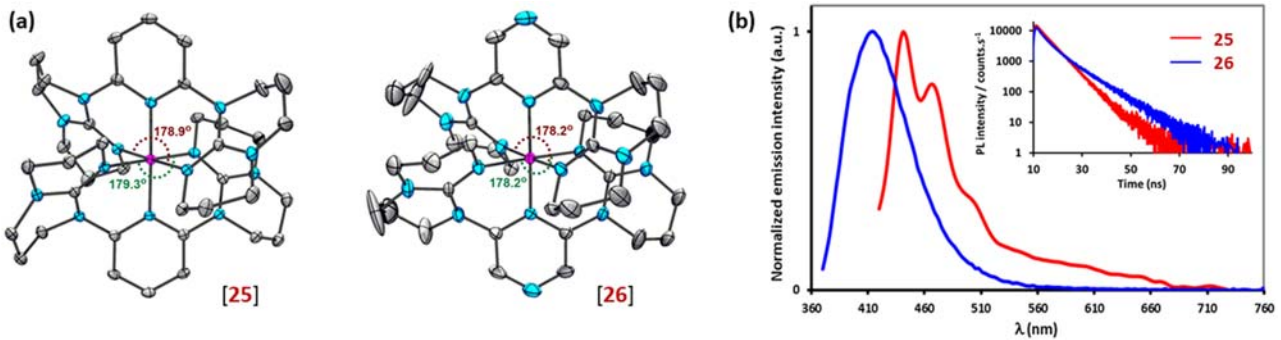

FIG. 8.3 (A) X-ray structures of **(25)** and **(26)** exhibiting the N^Co^N bite angles and (B) emission and excited-state lifetime decay (inset) profiles of complexes **(25)** and **(26)**. *Adapted from Pal, A.K., Krotkus, S., Fontani, M., Mackenzie, C.F.R., Cordes, D.B., Slawin, A.M.Z., et al., 2018. High-efficiency deep-blue-emitting organic light-emitting diodes based on iridium(III) carbene complexes. Adv. Mater. 30 (50), https://10.1002/adma.201804231. With Permission.*

The favorable excited-state redox properties of **(25)** and **(26)** helped in exploring the field of photochemical regioselective mono(trifluoromethylation) of polycyclic aromatic hydrocarbons (PAHs), e.g., pyrene, perylene, coronene and 9,10-diphenyanthracene using **(25)** and **(26)** as photocatalysts under mild reaction condition (CF_3SO_2Cl as the trifluoromethylating agent, irradiation at 420 nm, RT, 20 h) as compared to the reported traditional method of trifluoromethylation (CF_3I as the trifluoromethylating agent, 360°C, flame sealed ampule under high pressure) (Fig. 8.4). Due to the mild reaction photocatalytic condition, the reactions progressed to form selectively the mono(trifluoromethylation) PAHs in good yields (42%−58%) as opposed to multi(trifluoromethylation) PAHs (yield < 3%) prepared by the traditional method.

A possible reaction mechanism, using pyrene as the substrate and **(26)** as the photoredox catalyst (PRC) is depicted in (Fig. 8.4). The PAHs were themselves photoactive and can act as photosensitizers. Firstly, through energy transfer from the excited state of the photocatalyst, the excitation of pyrene occured to its triplet state **1**. The excited pyrene, **1**, underwent an oxidative quenching *via* a single electron transfer (SET) event with the trifluoromethylating agent, CF_3SO_2Cl to produce a pyrenyl radical cation **2** and $CF_3SO_2Cl^-$. This process was driven by the difference in the reduction potentials of **1** and CF_3SO_2Cl. The soformed $CF_3SO_2Cl^-$ produced a CF_3 radical **3** by the liberation of SO_2 gas. The electron-deficient CF_3 radical was then well-suited to add to the most electron-rich position of pyrene in a regioselective fashion to form a CF_3-pyrenyl radical, **4**. The resultant CF_3-pyrenyl radical, **4**, then under goes a second SET event with the excited photocatalyst,

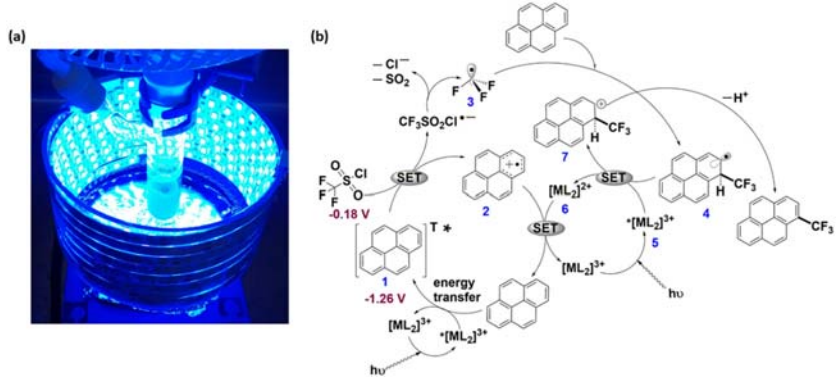

FIG. 8.4 (A) A photocatalytic trifluoromethylation reaction under experimental set-up and (B) mechanism of the trifluoromethylation of PAH using **(25)** and **(26)** as photocatalysts. *Adapted from Pal, A.K., Li, C., Hanan, G.S., Zysman-Colman, E., 2018. Blue-emissive cobalt(III) complexes and their use in the photocatalytic trifluoromethylation of polycyclic aromatic hydrocarbons. Angew. Chem. Int. Ed. 57 (27), 8027−8031. With Permission.*

5 (abbreviated as $*[ML_2]^{3+}$, where M = Co and L = dgpy/dgpz) to produce the reduced photocatalyst $[ML_2]^{2+}$, **6** and CF_3-pyrenyl cation, **7**. The formation of **6** was supported by in-situ reaction monitoring by UV-vis spectroscopy with the evolution of the band at 291 nm, which is a signature of $[ML_2]^{2+}$. A third SET event closed the two photocatalytic events, where **2** was reduced to pyrene and **6** was oxidized to $[ML_2]^{3+}$. Finally, deprotonation of **7** with K_2HPO_4 as the base afforded the desired CF_3-pyrene. As compared to another photoredox catalyst, $[Ir(dF(CF_3)ppy)_2(bpy)]PF_6$, reaction kinetics for mono(-trifluoromethylation) of pyrene using complex **(26)** was found to be slower, albeit resulted in a cleaner conversion of the product with high regioselectivity.

8.2.3 Metal-ion sensing by Co(II) complexes

Recently Liu et al. (2020) reported, five multi-functional luminescent coordination polymers (LCPs), $[Co_2(PNA)_2(PDA)_2]\cdot H_2O$, **(27)**, $[Co(PNA)(TPD)(H_2O)_2]\cdot 8H_2O$, **(28)**, $[Co(PNA)(1,3\text{-}BDC)]\cdot 2H_2O$, **(29)**, $[Co(PNA)(MIP)]\cdot H_2O$, **(30)** and $[Co_3(PNA)_3(HIPA)_3]$, **(31)**, [H_2PDA = 1,3-phenylenediacetic acid, H_2TPD = 2,5-thiophenedicarboxylic acid, 1,3-H_2BDC = 1,3-benzenedicarboxylic acid, H_2MIP = 5-methylisophthalic acid, H_2HIPA = 5-hydroxyisophthalic acid and PNA = [N,N′-bis(4-methylenepyridin-4-yl)-1,4-naphthalene dicarboxamide]. Polymers **(27−31)** were synthesized by a solution of $CoCl_2\cdot 6H_2O$, PNA and respective ligands in a mixture of water-NaOH in a poor yield of 14%−18%. The ligand PNA showed a $\pi \rightarrow \pi^*$ based fluorescence at 367 nm upon excitation at 250 nm in the solid-state. Upon similar excitation, the fluorescence of the LCPs was observed at 348−380 nm in the solid-state, which were attributed to the intraligand $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transitions. The difference in fluorescence intensities among the LCPs may be attributed to the difference in the respective ligand structures. The luminescent LCP **(27−29)** exhibited the property of sensing of metal cations (M = Na^+, K^+, Ba^{2+}, Zn^{2+}, Co^{2+}, Ni^{2+}, Mg^{2+}, Sr^{2+}, Sm^{3+}, Nd^{3+} and Fe^{3+} at a concentration of 10^{-2} M (Fig. 8.5). It was observed that among different cations, the increase in the $[Fe^{3+}]$ dramatically quenched the fluorescence of the LCPs, with a detection limit of $5.3-9.1 \times 10^{-4}$ and a Stern-Volmer quenching constant (K_{SV}) value of 2670−4789. The fluorescence quenching effect could be due to the donor-acceptor electron transfer effect of Fe^{3+} ions with PNA containing functional spacers. Similarly, toxic anions, such as $Cr_2O_7^{2-}$, CrO_4^{2-} and MnO_4^- significantly quenched the fluorescence of the LCPs **(27−29)** with maximum detection limits of 6.3×10^{-4} (for LCP **28**), 7.2×10^{-4} (for LCP **27**) and 6.5×10^{-4} (for LCP **29**) (Fig. 8.5). The luminescent LCP **(27)** was used as the potential fluorescent sensor of Bovine Serum Albumin (BSA) that exhibited a strong fluorescence peak at 350 nm (λ_{exc} = 280 nm) due to the presence of tryptophan, tyrosine and phenylalanine residues in BSA. It was observed that on increasing the concentration of LCP **(27)**, the emission intensities of BSA

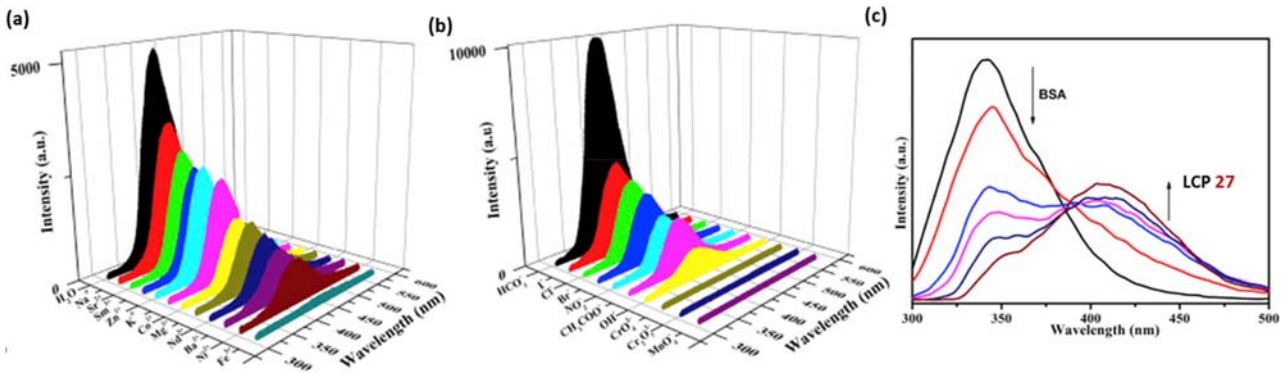

FIG. 8.5 (A) Fluorescence emission intensities of M^{n+}@LCP **(27)**, (B) fluorescence emission intensities of LCP **(27)** in different anion solution and (C) fluorescence spectra of BSA@LCP **(27)**. *Adapted from Liu, G.C., Li, Y., Chi, J., Xu, N., Wang, X.L., Lin, H.Y., et al., 2020. Multi-functional fluorescent responses of cobalt complexes derived from functionalized amide-bridged ligand. Dyes Pigm., 174, https://10.1016/j.dyepig.2019.108064. With Permission.*

and corresponding LCP **(27)** gradually decreased and increased, respectively, due to the supramolecular hydrogen bonding interaction between the LCP **(27)** and BSA. Similarly, as the concentration of LCP **(27)** increased from 0 to 40 μL, the τ_{PL} value of BSA decreased from 6.07 to 5.91 ns.

A hydrothermally synthesized novel $\{[Co(SBzIm)_2(npht)]\cdot H_2O\}_n$, **(32)**, [$H_2$npht = 5-nitrophthalic acid, SBzIm = 1,4-bis(thiabendazol-1-ylmethyl) benzene)] complex was investigated by Shi et al. (2020). A mixture of $Co(OAc)_2\cdot 4H_2O$, SBzIm, H_2npht, NaOH and distilled water were mixed and heated for 72 h at 140°C to afford **(32)** in 34% yield. The SBzIm exhibited an emission peak at 297 nm (λ_{exc} = 276 nm) in the solid-state, due to the ligand-based $\pi \rightarrow \pi^*$ transitions. The complex **(32)** exhibited a red-shifted emission peak at 376 nm (λ_{exc} = 298 nm), which was tentatively assigned to the ^{3}ILCT transitions. The emission of complex **(32)** exhibited solvatochromic effects in different solvents, e.g., ethylene glycol (EG), *N,N′*-DMF, MeCN, *n*-butanol, MeOH, EtOH, dichloromethane, *p*-xylene and acetone. Among these solvents, EG showed 97.8% fluorescence quenching of **(32)** and the calculated K_{SV} and the detection limit values were found to be 4.8×10^2 M and 2.5 mM, respectively. The complex **(32)** exhibited the property of sensing of metal cations, M = K^+, Na^+, Pb^{2+}, Cd^{2+}, Zn^{2+}, Cu^{2+}, Co^{2+}, Sr^{2+}, Mg^{2+}, Ca^{2+}, Fe^{3+}, Sm^{3+}, La^{3+}, Eu^{3+} or Cr^{3+}, at a concentration of 5×10^{-4} M. It was observed that among different cations, the increase in the concentration of Cu(II) from 0 to 0.50 mM displayed the increase in fluorescence quenching of **(32)**, leading to almost disappearance of the emission of **(32)** at the maximum [Cu(II)]. The K_{SV} and the detection limit of Cu(II) using complex **(32)** were found to be 1.4×10^3 M and 1.0 μM, respectively. Su et al. (2020) also reported a hydrothermally synthesized novel 2D Co(II) organic framework, $\{[Co_2(ImPh)(hfpd)(H_2O)]\cdot 1.75H_2O\}_n$, **(33)**, ($H_4$hfpd = 4,4′-(hexafluoroisopropylidene)diphthalic acid, ImPh = 4,4′-bis(imidazole-1-yl)-biphenyl) for the reorganization and quantification of highly carcinogenic acetylacetone (acac) and mercury (Hg(II)) ion. A mixture of $Co(SO_4)_2$, H_4hfpd, ImPh and NaOH in a 2:1:1 metal:H_4hfpd:ImPh ratio was heated in water at 140°C for 3 days in a Teflon lined steel container to afford the complex in a 51% yield. Complex **(33)** was crystallized in a triclinic space group in which the asymmetric unit **(33)** had two Co(II) centers, one $[hfpd]^{4-}$ ligand, one ImPh ligand and one coordinated water molecule. The six-coordinated Co1(II) and four-coordinated Co2(II) surrounded by O and N atoms displayed distorted octahedral $\{CoNO_5\}$ and distorted trigonal-pyramidal $\{CoNO_3\}$ coordination geometries, respectively. The ligand ImPh exhibited an emission peak at 407 nm in the solid-state, which can be attributed to $\pi \rightarrow \pi^*$ or $n \rightarrow \pi^*$ based transitions within the ligand ImPh. Complex **(33)** exhibited luminescence at 356 nm (λ_{exc} = 294 nm) which was tentatively assigned to intraligand or ^{3}LLCT transition. Luminescence of **(33)** in different solvents, such as EG, MeOH, EtOH, n-butanol, acac, *N,N′*-dimethyl acetamide, DMSO, MeCN, etc. revealed that the luminescence in

acac was almost completely quenched with a quenching efficiency ($Q = (1-I/I_0) \times 100\%$, where I_0 and I are the luminescence intensities without adding and adding acac, respectively) ~99.46% (Fig. 8.6A). Anti-interference experiments suggested that the luminous intensity of **(33)** in presence of acac and other organic solvents showed no significant difference, hence complex **(33)** was found to be a very selective sensor for the detection of acac (Fig. 8.6B). The calculated values of K_{SV} and the detection limit of acac were found to be 1915 M^{-1} and 14 μM, respectively. Complex **(33)** exhibited the property of sensing of metal cations ($M = Na^+$, K^+, Mg^{2+}, Sr^{2+}, Ba^{2+}, La^{3+}, Sm^{3+}, Eu^{3+}, Tb^{3+}, Fe^{3+}, Co^{2+}, Ni^{2+}, Cu^{2+}, Ag^+, Zn^{2+}, Cd^{2+} and Hg^{2+}) (Fig. 8.6C). It was observed that among different cations, the increase in the $[Hg^{2+}]$ dramatically quenched the luminescence of **(33)**; the calculated value of Stern-Volmer constant K_{SV} was 6497 M^{-1} with an associated detection limit of 4 μM (Fig. 8.6D).

8.3 Luminescent Rh(0/I/II/III) complexes

8.3.1 Rh(II/III) complexes of acetylacetonato, polypyridylamine, thiolato and macrocyclic ligands

DeArmond and Hillis (1968) studied the luminescence properties of Rh(III) complexes, e.g., $[Rh(acac)_3]$, **(34)**, $[Rh(tfacac)_3]$, **(35)**, $[Rh(hfacacac)_3]$, **(36)** with various β-diketone chelates (where tfaca = trifluoracetylacetone and hfacacac = hexafluoroacetylacetone). These complexes **(34–36)** exhibited emission maxima and FWHM in the ranges 413–419 nm and 2100–3600 cm^{-1}, respectively. The nature of the emission was attributed as $\pi \rightarrow \pi^*$ triplet to singlet ($T \rightarrow S_o$) transition. The excited-state lifetime (τ_{PL}) of these complexes ranges from 310 to 390 ms. The calculated lowest singlet-triplet energy for these ligand systems was 2.30–2.70 eV, which supported the emission of the $Rh(acac)_3$ complexes. Later, Carstens and Crosby (1970) observed the photoluminescence of some Rh(III) complex ions $[Rh(bpy)_3]^{3+}$, **(37)** and $[Rh(phen)_3]^{3+}$, **(38)**. These complexes were synthesized by adding the 2,2′-bpy or 1,10-phen ligand to a refluxing aqueous-ethanol solution of rhodium(III) chloride in ~70–90% yield (McKenzie and Plowman, 1970). In emission spectra, complexes **(37)** and **(38)** at 77 K exhibited long-lived $\pi \rightarrow \pi^*$ phosphorescence which was similar to that observed from the free ligand (Halper and DeArmond, 1974). Complex **(37)** is also known to exhibit a ^{3}IL excited state. Hillis and DeArmond (1971a) studied the emission properties of Rh(III) complexes $[Rh(bpy)_3]Cl_3$, **(37)**, $[Rh(phen)_3]Cl_3$, **(38)** and $[Rh(en)_3]Cl_3$, **(39)** with nitrogen donor ligands (where en = ethylenediamine). The complex **(39)** was synthesized by adding an excess of ethylenediamine to a warm alcoholic solution of rhodium trichloride trihydrate (Gillard et al., 1965). In emission spectrum, complexes **(37–39)** at 77 K varied from 450 to 588 nm and

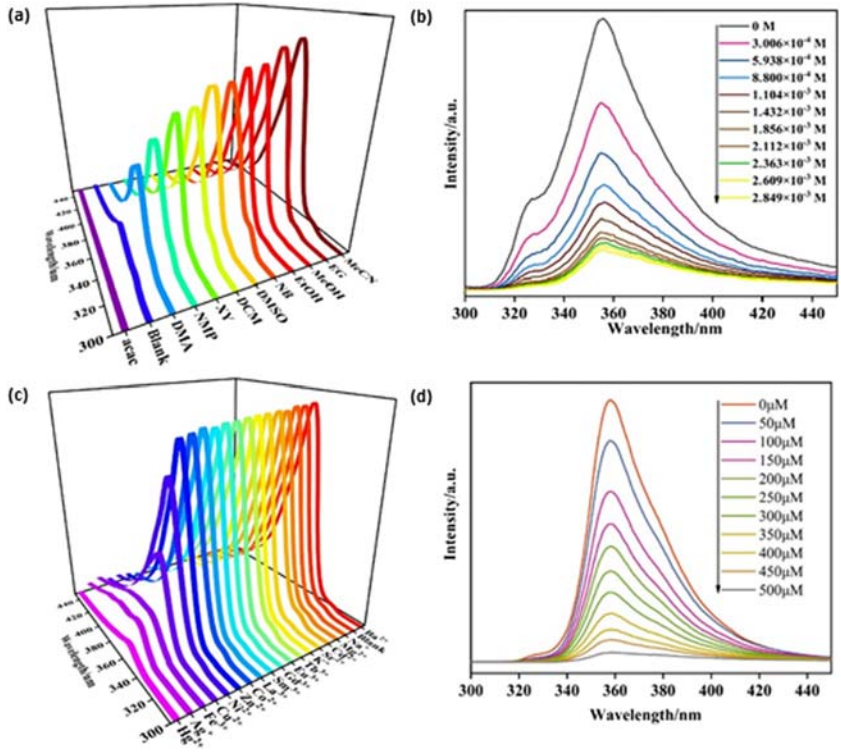

FIG. 8.6 (A) Luminescent intensities for **(33)** dispersed in aqueous solution upon dropping different organics; (B) emission spectra of **(33)** dispersed in aqueous solutions with different concentrations of acac at RT; (C) luminescent intensities of **(33)** immersed in EtOH with various metal ions and (D) emission spectra of **(33)** in EtOH suspension with different concentrations of [Hg^{2+}] ions. *Adapted from Su, Y.Q., Qu, Y.H., Fu, L., Cui, G.H., 2020. An unprecedented binodal (4,6)-connected Co(II) MOF as dual-responsive luminescent sensor for detection of acetylacetone and Hg^{2+} ions. Inorg. Chem. Commun., 118, https://10.1016/j.inoche.2020.108013. With Permission.*

lifetimes (τ_{PL}) 0.02 **(39)**, 2.20 **(37)** and 47−48.4 **(38)** ms (Hillis and DeArmond, 1971a,b; Kalyanasundram et al., 1992). The Φ_{PL} values at 77 K were found to be 29%, 90% and 0.09% for **(37)**, **(38)** and **(39)**, respectively, upon excitation at 313 nm (Hillis and DeArmond, 1971a). Kalyanasundaram et al. (1992) further studied complexes **(37)** and **(38)**, where they reported that emission maxima were obtained at 454 and 579 nm with associated τ_{PL} values of <15 and 220 ns, respectively, at 293 K in acetonitrile. Complexes **(38)** and **(39)** exhibited structured emission principally at 483 nm with shoulders at 450, 510 and 553 nm in EtOH:MeOH (4:1 v/v) at 77 K. These emissions were tentatively attributed to the ligand-centered (^{3}LC) $\pi \rightarrow \pi^*$ or metal-centered (^{3}MC) d → d transitions, where, the ^{3}MC emission was the dominant feature at 77 K, but the LC emission was enhanced relative to the MC luminescence

in fluid solutions. The lifetimes of the complexes were found to be 30−40 times shorter than those of the respective free ligands.

Geoffroy et al. (1974) synthesized two Rh(I) phosphine complexes, e.g., [Rh(2-phos-ene)$_2$]Cl, **(40)** and [Rh(2-phos)$_2$]Cl, **(41)**, (2-phos-ene = *cis*-l,2-bis(diphenylphosphino)ethylene and 2-phos = 1,2-bis(diphenylphosphino) ethane). These complexes were synthesized adopting the method of Vaska and Catone (1966) by mixing a benzene solution of the reactants, ligands and [Rh(CO)Cl(PPh$_3$)$_2$] at 25°C, followed by decarbonylation in a 10:1 mixture of toluene:1-propanol at 100°C. Complex **(40)** exhibited luminescence at 606 nm in the solid-state at RT with associated FWHM of 2880 cm^{-1} and τ_{PL} value of 22.3 μs. The complexes **(40)** and **(41)** in EPA solution [5:5:2 (v/v/v) ethyl ether:isopentane:ethyl alcohol) at 77 K exhibited λ_{em} at 584 and 613 nm, with FWHM of 2890 and 2120 cm^{-1}, respectively. The τ_{PL} and Φ_{PL}values of complexes **(40)** and **(41)** at 77 K were found to be 20.8 μs, 27.5 μs and 75%, 5.2%, respectively (Geoffroy et al., 1974).

Two *tris*(dithioketone) complexes of Rh(III), e.g., [Rh(SacSac)$_3$], **(42)** and [Rh(SSBB)$_3$], **(43)**, (where SacSac = dithioacetylacetone and SSBB = dithiodibenzoylmethane) were synthesized by Merrill and DeArmond (1979). Complex **(42)** was synthesized following the procedure developed by Heath and Martin (1969) in a yield of 3%. Complex **(43)** was synthesized by adding an aqueous solution of $RhCl_3$ into a suspended ethanolic solution of $NaBH_4$ and 3,5-diphenyl-1,2-dithiolium chloride. The resulting mixture was refluxed for 2 h to afford the complex **(43)** in 35% yield. The emission spectra of **(42)** and **(43)** are broad, asymmetric and overlap substantially with the absorption spectra. The differences between the energy of the emission maximum and the energies of the intensities at one-half of the emission maximum were found to be 960 and 1250 cm^{-1} for the blue side and red side, respectively, in complex **(42)**. Thus, the emission spectra of complexes **(42)** and **(43)** could each be represented by the sum of two Gaussian functions. Without the Gaussian deconvolution, complexes **(42)** and **(43)** exhibited luminescence at ∼ 794 and ∼ 833 nm, respectively, in ETA at 77 K with associated FWHM of 2210 and 2150 cm^{-1}. The Gaussian fit values of complex **(42)** were found to be 12,750, 12,000 cm^{-1} with associated FWHM at 1710 and 2570 cm^{-1}, respectively. Similarly, the Gaussian fit values of complex **(43)** were found to be 12,230 and 11,590 cm^{-1} for luminescence with associated FWHM of 1580 and 2300 cm^{-1}, respectively. The fitting of two Gaussian components was found to be consistent with the two-exponential fit of the excited-state lifetime decay-curve data. Complexes **(42)** (λ_{exc} = 764 nm) and **(43)** (λ_{exc} = 801 nm) exhibited τ_{PL} values of 10.9 and 3.8 μs (short component) and 30.8 and 63.6 μs (long component) in methylcyclohexane. The two-Gaussian fit, multiple lifetimes and polarization spectra indicated that the emission occurred from two different states. The half-width of the broader band from the two-Gaussian fits suggested the assignment of this band as ^{3}(d-d) → $^1A_1$, while from the

charge transfer-to-metal visible absorption band position and the solvent dependence of the emission, the other band was assigned as $^3(\pi\text{-}d^*) \rightarrow {}^1A_1$.

A new series of Rh(I) complexes $[Rh(CO)_2(mnt)]^-$, **(44)**, $[Rh(CO)(PPh_3)(mnt)]^-$, **(45)** and $[Rh(P(OPh)_3)_2(mnt)]^-$, **(46)**, (mnt = maleonitriledithiolate) was reported by Johnson et al. (1983). The complexes were synthesized by mixing sodium maleonitriledithiolate and respective tetrabutylammonium rhodium salt in (1:1 v/v) acetone:ethanol for several hours until the product was formed as a brown precipitate. The solid-state luminescence spectra of complexes **(44–46)** at 77 K exhibited emission values at 609, 619 and 603 nm and associated τ_{PL}values of 238, 99 and 281 μs, respectively, in EPA. The τ_{PL}values for the Rh complexes were found to belong as expected for the spin-forbidden transition based on their high spin-orbit coupling constants. The emission spectra of all the complexes were tentatively assigned to (i) the mnt-based intraligand (IL) $\pi \rightarrow \pi^*$ state, (ii) MLCT state involving mnt and (iii) LMCT state involving mnt. The solid-state emissions were highly structured with a major vibrational progression value of 1400 cm^{-1}.

The luminescence properties of a series of red-emissive Rh(III)-amine complexes were investigated by Sexton et al. (1984). Only a few of these, e.g., $[Rh(NH_3)_5Cl](ClO_4)_2$, **(47)**, *trans*-$[Rh(NH_3)_4Cl_2]Cl\cdot H_2O$, **(48)**, *trans*-$[Rh(NH_3)_4(H_2O)Cl](ClO_4)_2$, **(49)**, *trans*-$[Rh(NH_3)_4(OH)Cl]$, **(50)** are mentioned here. In general, the intensities of emission followed the order:

$$Rh(NH_3)_5X_2^+ >> \textit{trans}\text{-}Rh(NH_3)_4X_2^+ > \textit{cis}\text{-}Rh(NH_3)_4X_2^+ > \textit{trans}\text{-}Rh(NH_3)_4(OH)X^+ > \textit{cis}\text{-}Rh(NH_3)_4(OH)X^+ > \textit{cis}\text{-and } \textit{trans}\text{-}Rh(NH_3)_4(H_2O)X^{2+}.$$

Bromo compounds were generally brighter emitters than the homologous chloro complexes. No emission was found for the dihydroxo complexes, *cis*- and *trans*-$Rh(NH_3)_4(OH)_2^+$. For the series of $Rh(NH_3)_4XY^{n+}$ complexes, (X = either $C1^-$ or Br^-), the λ_{em}, values at 77 K followed the order:

$$Y = NH_3 > \textit{cis}\text{- or } \textit{trans}\text{-OH} > \textit{trans}\text{-X} > \textit{cis}\text{-X} \sim H_2O.$$

A similar situation was observed with the $\lambda_{0\text{-}0}$ values, which followed the apparent order:

$$Y = NH_3 > OH > \textit{cis}\text{- or } \textit{trans}\text{-X} \sim H_2O.$$

At both 77 and 298 K, the complexes exhibited a broad Gaussian distribution of luminescence. Complexes **(47–50)** at 77 K in 4:1 (v/v) MeOH:water glasses exhibited ligand field red-phosphorescence at 666, 763, 775 and 699 nm with associated FWHM at 0.28, 0.25, 0.29 and 0.27 μm^{-1}, respectively. Photoexcitation of the haloamminerhodium(III) complexes at 298 K aqueous solution led to two emission components, a very fast (picosecond) decay, which was attributed to fluorescence from incompletely relaxed LF singlets and as lower (nanosecond) decay, which was attributed to the phosphorescence from a thermally relaxed lowest energy triplet LF state. The

lifetime of complexes at 77 K was found to be longer (in μs) compared to those in aqueous conditions at 298 K (in ns). The quantum yields for emission were found to be in the range $10^{-7} < \Phi_{PL} < 10^{-6}$. Later, Frink et al. (1988) synthesized some interesting NIR emissive Rh(III)-terpyridyl complexes, e.g., $[Rh(tpy)_2]^+$, **(51)**, $[Rh(tpy)(bpy)(py)]^{3+}$, **(52)** and $[Rh(tpy)(bpy)C1]^{2+}$, **(53)**, (bpy = 2,2′-bipyridine; py = pyridine, tpy = 2,2′:6′,2″-terpyridine). Complex **(51)** was synthesized by the reaction of tpy with $Rh(tpy)Cl_3$ Haris and McKenzie (1963). Complex **(52)** was synthesized by refluxing a mixture of $[Rh(tpy)(bpy)Cl](ClO_4)_3 \cdot 3H_2O]$, pyridine and ethanol for 10 h. Ether was added in excess to the cooling solution leading to the formation of complex **(52)**. Complex **(53)** was synthesized by refluxing $Rh(tpy)Cl_3$ and bpy in a mixture of dimethylformamide and ethanol for 6 h. The mixture was cooled and filtered, and then ether was added to the filtrate to yield the desired product. Emission spectra for complexes **(51)**, **(52)** and **(53)** at 77 K, when measured in EtOH:MeOH (4:1, v/v) glasses exhibited λ_{em} at 735, 730 and 763 nm and τ_{PL} values of 8.0, 16.5 and 9.3 μs, respectively. The Φ_{PL} values at 77 K were found to be 9%, 8% and 10% for **(51)**, **(52)** and **(53)**, respectively. In aqueous solutions at 298 K, τ_{PL}values for **(51)** and **(52)** at 10^{-3} M were found to be three orders of magnitude lower than those at 77 K, with values of 14.2 and 14.9 ns, respectively, and emission intensities were found to be very weak. The emission spectra at both the temperatures displayed broad Gaussian-shaped bands resulting from the lowest energy excited ^{3}LF state.

Rh(III) complexes with mixed-chelates, namely $[Rh(ppy)_2bpy]^+$, (ppyH = phenylpyridine), **(54)**, $[Rh(ppy)_2en]^+$, **(55)** and $[Rh(thpy)_2bpy]^+$, (thpyH = thienylpyridine), **(56)** were also studied Colombo et al. (1990). At low-temperature in the visible part of the spectrum, luminescence spectra of Rh(III) complexes with π-accepting ligands in glassy matrices are characterized by a structured band. At 6 K, luminescence spectrum of complex **(54)** in nitrile glass having a range of 454−625 nm exhibited the wide luminescence lines from 100 to 200 cm^{-1} when excited at 337 nm. The complex **(54)** was earlier reported to be emissive also at 454 nm both at 222 and 77 K with a structured profile (Maestri et al., 1987). The τ_{PL} values were measured to be < 0.05 μs and 0.17 ms, respectively, at 222 and 77 K. The width was inhomogeneously arising from the broad distribution of sites in the glass. The LLN (LLN = Luminescence Line Narrowing) spectra of $[Rh(ppy)_2bpy]^+$, **(54)**, $[Rh(ppy)_2en]^+$, **(55)** and $[Rh(thpy)_2bpy]^+$, **(56)** in a nitrile glass or in Plexi glass was investigated. It was observed that substitution of bpy by en in **(54)** had almost no effect on the sharp-line pattern of the complex. Therefore, following the previous study, it was concluded that the ppy^- ligand was involved in the lowest energy excited state of **(53)** which, in addition, was further confirmed by the spectrum obtained by substituting the ligand ppy^- with $thpy^-$ (Maestri et al., 1987). Further to understand the nature of the first excited state, an extended-Hückel calculation on model complexes **(54)** and **(55)** were performed. The lowest energy unoccupied orbital turned out to be a

bpy-based orbital from the calculations. The lowest energy excited states in both these complexes were assigned to $\pi \rightarrow \pi^*$ on the cyclometalated ligand. The LLN experiments showed that the cyclometalated ligand were involved in the first excited state and not bpy. In a later report by Kunkely and Vogler (2000), the blue-green photoluminescence ($\lambda_{em} = 460$, 490 nm, $\Phi_{PL} = 0.006$) of $[Rh(ppy)_2(CN)_2]^{2-}$, **(57)**, (ppy = 2-phenylpyridinato-C^2,N') was attributed to be ^{3}LC in character. Due to the presence of higher LF strength in complex **(57)**, it showed brighter luminescence at RT than the other previously reported Rh(III)-ppy analogs.

Dulebohn et al. (1990) explored the luminescence properties of dirhodium $Rh_2(0,0)$, $Rh_2(0,II)$ and $Rh_2(II,II)$ fluorophosphine complexes, e.g., $[Rh_2(dfpma)_3(PF_3)_2]$, **(58)**, $[Rh_2(dfpma)_3Cl_2(PF_3)_2]$, **(59)**, $[Rh_2(dfpma)_3Cl_4]$, **(60)**, respectively, (where dfpma = $CH_3N(PF_2)_2$ = bis(difluorophosphino) methylamine). Complex **(58)** was synthesized by mixing $CH_3N(PF_2)_2$ and DCM solution of $[RhCl(PF_3)_2]_2$. The change in the color of solution was accompanied by the liberation of PF_3. Then the $Co(C_5H_5)_2$ was added. The mixture was stirred for 10 min under PF_3 and the addition of hexane led to the precipitation of cobaltocene, which was filtered out to afford the complex in 32% yield. Complex **(59)** was synthesized by mixing benzene solution of $[RhCl(PF_3)_2]_2$ and $CH_3N(PF_2)_2$ with a yield of 25%. Complex **(60)** was synthesized in the same way as **(58)**, where unlike **(58)**, the PF_3^- anion was exchanged with Cl^- by the addition of $Cl_2IC_6H_5$ to give 59% yield **(60)**. In a different study, kadis et al. (1996) synthesized structurally similar two more complexes, $[Rh_2^{(0,II)}(dfpma)_3Br_2(\eta^1\text{-dfpma})]$, **(61)** and $[Rh_2^{(II,II)}(dfpma)_3Br_4]$, **(62)** which were synthesized by refluxing $CH_3N(PF_2)_2$ and benzene solutions of $[RhBr(PF_3)_2]_2$ for 9 and 3.5 h, respectively. Br_2 was added to synthesize **(62)**. The vibrationally featureless emission spectra of complexes **(58–60)** in crystalline form at 77 K, exhibited λ_{em} at 840, 780 and 820 nm with associated τ_{PL} values of 53, 79 and 287 μs, respectively. The red-emissions in these complexes were attributed to $^3(d\pi^* \rightarrow d\sigma^*)$ phosphorescence. The intensities of the emissions monotonically decreased with increasing temperature and the FWHM of emission bands exhibited a substantial temperature sensitivity, increasing by more than 1500 cm^{-1} from 10 K to the highest temperatures at which emission can be detected. The lack of luminescence in solution at temperatures equivalent to those at which the crystalline solids demonstrated the importance of medium rigidity as a crucial controlling factor of $d\sigma^*$ luminescence. It was indicated that with the two-electron mixed-valence $Rh_2(0,II)$ complex as a benchmark, the preparation of its multielectron $Rh_2(0,0)$ and $Rh_2(II,II)$ counterparts could be achieved such that a long-lived emissive $d\sigma^*$ excited state can be preserved. Conversion of the octahedral Rh(II) center of **(59)** to the trigonal-bipyramidal Rh(0) center of **(58)** stabilized a formally highly energetic level that could accommodate the addition of two electrons to the metal core. In this manner, the overall electronic structure necessary for $d\sigma^*$ luminescence was preserved. Complexes **(58–62)** also

exhibited $^3(d\pi^* \rightarrow d\sigma^*)$ based phosphorescence maxima ranging from 760 to 850 nm in dichloromethane at 77 K with associated τ_{PL} values of 74, 270, 190, 300 and 79 μs, respectively, in the amorphous solid state.

Kalyanasundaram et al. (1992) studied the luminescence properties of Rh(III)-polypyridyl complexes of the type, $[Rh(dpp)_2C1_2]^+$, **(63)**, $[Rh(bpy)_2(dpp)]^{3+}$, **(64)** and $[Rh(dpp)_2(bpy)]^{3+}$, **(65)**, (dpp = 2,3-bis(2-pyridyl)pyrazine). Complex **(63)** was synthesized by refluxing $RhC1_3 \cdot 3H_2O$ and the ligand dpp in an ethanol:water (2:1 v/v) mixture whereas complexes **(64)** and **(65)** were synthesized by refluxing $RhC1_3 \cdot xH_2O$ and ligand bpy/dpp, in DMF. At 293 K, complex **(63)** in acetonitrile showed a very weak emission for which the τ_{PL} was calculated to be 90 ns by transient absorption method. Both complexes **(64)** and **(65)** in acetonitrile at 293 K exhibited λ_{em} at 450 nm with τ_{PL}values of 390 and 800 ns, respectively. These transitions were tentatively assigned as an admixture of primarily $\pi \rightarrow \pi^*$ transitions with a minor contribution from d $\rightarrow$ d transitions. At 77 K, in EtOH:MeOH (4:l v/v), complexes **(64)** and **(65)** exhibited λ_{em} principally at 484 and 477 nm, respectively, with shoulders ranging from 445 to 543 nm. These emissions were attributed due to $\pi \rightarrow \pi^*$ based transitions. The τ_{PL} of complexes **(64)** and **(65)** were found to be 2.25 and 2.05 ms at 77 K. Complexes **(63)**, **(64)** and **(65)** also exhibited a very weak secondary emission in the range of 704−758 nm with associated τ_{PL}values of $\sim$19.6−24 μs in the same solvent mixture at 77 K. These emissions were attributed to d $\rightarrow$ d transitions.

Rh(III) complexes were also reported with some tetrazamacrocyclic ligands, e.g., *trans*-[Rh([14]aneN$_4$)(CN)$_2$]C1O$_4$, **(66)**, *trans*-[Rh([15]aneN$_4$)(CN)$_2$]C1O$_4$, **(67)**, *trans*-[Rh([14]pyaneN$_4$)(CN)$_2$](C1O$_4$)$_3$, **(68)**, (McClure and Ford, 1992). Complexes **(66−68)** were synthesized by refluxing the aqueous solution of *trans*-dichloro([14]aneN$_4$)rhodium(III) chloride, *trans*-dichloro([15]aneN$_4$)rhodium(III)chloride or *trans*-dichloro([14]pyaneN$_4$)-rhodium(III) perchlorate and NaCN for about 4−24 h. The anion was metathesized by ClO_4^- by the addition of an aliquot of aqueous $NaClO_4$ to afford the complex with in a yield of 45%−53%. Complexes **(66)** and **(67)** exhibited broad and unstructured strong spin-forbidden emissions from the lowest energy ^{3}LF states at 468 and 570 nm, respectively, in an aqueous acidic solution (pH = 4, $HClO_4$) with associated τ_{PL}values of 8.1 and 0.74 μs. The Φ_{PL} values at 296 K in aqueous solution for the perchlorate salts of **(66)** and **(67)** were found to be 0.25 and 0.018. The broad, unstructured emission spectra of complexes from **(65−67)** at 77 K in MeOH:H_2O (4:1 v/v) glasses exhibited λ_{em} at 472, 529, 610 nm with associated FWHM at 4400, 3900 and 3400 cm^{-1}, respectively. The τ_{PL} values of **(65−67)** were found to be 286, 56 and 15.4 μs, respectively at 77 K. The 0 $\rightarrow$ 0 transition energies were found to be 26,900, 23,900 and 20,700 cm^{-1}, respectively, from the 77 K experiments.

An interesting cyclometalated Rh(III) complex $[Rh(ppy)_2(dpt\text{-}NH_2)]PF_6$, **(68)**, (dpt-NH$_2$ = 4-amino-3,5-bis(2-pyridyl)-4*H*-1,2,4-triazole) was

synthesized by Calogero et al. (1995). Complex **(68)** was synthesized by adding a dichloromethane solution of $[Rh(ppy)_2C1]_2$ to a refluxing dichloromethane solution of dpt-NH_2. After the anion metathesis with PF_6^-, the product was obtained in a good yield of 87%. Complex **(68)** exhibited highly structured luminescence with λ_{em} at 458 nm at 77 K in rigid matrices, with 4:1 MeOH:EtOH (v/v), which was attributed to the metal-perturbed, triplet ppy-centered (^{3}LC) excited state with mono-exponential τ_{PL} value of 160 μs. This assignment was confirmed by the lack of RT luminescence of **(68)**, as the ^{3}LC states were effectively deactivated by the thermal population to upper-lying ^{3}MC levels, which finally got deactivated by fast radiationless transitions to the ground state. The structured luminescence spectra do not vary with the excitation wavelength and exhibited a vibrational progression of about 1300 cm^{-1}. In comparison to the previously reported $[Rh(ppy)_2(bpy)]^+$, **(54)**, ($\lambda_{em} = 454$ nm, $\tau_{PL} = 170$ μs at 77 K in 4:1 MeOH:EtOH (v/v)), complex **(68)** showed emission from a ppy-centered orbital mixed with an upper-lying CT level (Colombo et al., 1990). Since the dpt-NH_2 is a slightly better donor group than bpy and could move the Rh $\rightarrow$ ppy CT level to lower energy, it could decrease the energy gap between ^{3}LC and ^{3}MLCT states, promoting a better mixing and leading to a shortened lifetime. Complex **(68)** displayed irreversible oxidation peaks at +1.51 V and reduction peaks at −1.90 V *vs* SCE, attributed to the removal and addition of an electron from a metal-ligand (C^-) σ-bonding orbital and the dpt-NH_2 ligand, respectively.

Two interesting optically active cyclometalated Rh(III) complexes, Δ[Rh(thpy4,5p(R,R)py)$_2$TAP]Cl, **(69)** and Δ[Rh(phpy4,5p(R,R)py)$_2$TAP]Cl, **(70)**, (where TAP = 1,4,5,8-tetraazaphenanthrene; thpy4,5p(R,R)py = (8R,10R)-2-(2′-thienyl)-4,5-pinenopyridine and phpy4,5p(R,R)py = (8R,10R)-2-(2′-phenyl)-4,5-pinenopyridine) were reported (Ghizdavu et al., 2003). Complexes **(69)** and **(70)** were synthesized with a yield of 76%−85% by refluxing a solution of $\Delta\Delta$[Rh(thpy4,5p(R,R)py)$_2$(μ-Cl)]$_2$/$\Delta\Delta$[Rh-(phpy4,5p(R,R)py)$_2$(μ-Cl)]$_2$ and TAP in CH_2Cl_2 for $\sim$2 h under N_2 in dark. Complexes **(69)** and **(70)** exhibited broad and structureless ^{3}CT based (from thpy/phpy $\rightarrow$ TAP) red to near-infrared emission (λ_{em} and $\tau_{PL} = 720$ nm and 11 ns (for **69**) and 647 nm and 152 ns (for **70**)) at 298 K in acetonitrile. The complexes **(69)** and **(70)** exhibited broad-structured and structureless luminescence centered at 526 and 553 nm with associated τ_{PL} values of 5.8 ± 0.5 (a shorter component present couldn't be determined precisely) and 9 μs, respectively, at 77 K in EtOH:MeOH (4:l(v/v)) matrix. The nature of the emissions of **(69)** at 77 K was ascribed as a mixture of ^{3}CT (from thpy to TAP) and $^3LC_{\pi\text{-}\pi^*}$ (centered on thpy), while the same for **(70)** was due to ^{3}CT emission (from phpy to TAP) only. This is due to three probable reasons as suggested by TD-DFT calculations (a) energy differences among the first four triplets were larger in **(70)** than in **(69)** such that the nonradiative transitions from T_4 to T_3, T_2 and T_1 was favored for the former, (b) the radiationless

decays from T_4 to T_3 and T_2 to T_1 was found to be favored in **(70)** as compared to **(69)** as T_4 andT_3 have the same orbital parentage as well as T_2 and T_1 in **(70)**, which was not the case for the corresponding pairs of triplets (T_4-T_3 and T_2-T_1) in **(69)** and (c) although in both these complexes; the decay concerned a transition from an LC state to a CT state (CT from the orthometalated to the TAP ligand). The LC state was localized on the TAP in complex **(70)** whereas, the LC state was localized on the orthometalated ligand in **(69)**. Thus, a different electron transfer process was implied for the transition $^3LC_{\pi\text{-}\pi^*}(T_3) \rightarrow CT(T_2)$ in the complexes.

8.3.2 Metal-ion sensing by Rh(III) complexes

Luminescent Rh(III) complex, e.g., $[Rh(L)(ppy)_2]PF_6$, **(71)**, (L = (E)-3′,6′-bis(ethylamino)-2′,7′-dimethyl-2-((pyridin-2-ylmethylene)amino)spiro[isoindoline-1,9′-xanthen]-3-one) has also been employed for cation sensing application (Wang et al., 2015). Complex **(71)** displayed emission at 548 nm in MeCN at RT, which was suggested to be derived from the triplet excited state of intraligand (^{3}IL) [$\pi \rightarrow \pi^*$(NˆC)] transition, mixed with the metal-to-ligand charge transfer (^{3}MLCT) [dπ(Rh) $\rightarrow \pi^*$(NˆC)] character. The probability of mixing this emission with the characteristic rhodamine 6G emission due to the occurrence of ring-opening was not ruled out. Complex **(71)** exhibited sensing behavior to $[Hg]^{2+}$ by inducing the ring-opening of the rhodamine derivative with an emerging absorption band at 530 nm (Fig. 8.7). The log K_s value of 4.04 for $[Hg]^{2+}$ ion binding was estimated from the satisfactory result of the theoretical fit of the 1:1 stoichiometric binding mode with a detection limit of 4×10^{-7} M.

8.3.3 Application of Rh(III) complexes in OLED devices

An extensive and interesting work on OLEDs was reported by Wei et al. (2019), where they synthesized a series of luminescent cyclometalated Rh(III) complexes $[Rh(dpqx)_2(acac)]$, **(72)**, $[Rh(dpqx)_2(hfacac)]$, **(73)**, $[Rh(dpqx)_2(Ph_2\text{-acac})]$, **(74)**, (where, dpqx = 2,3-diphenylquinoxaline, Ph_2-acac = 1,3-diphenylpropane-1,3-dione) in which the luminescence quenching problem from the lowest-lying d-d state was overcome by the incorporation of a strong σ-donor cyclometalating ligand with lower-lying IL state (Fig. 8.8A). The complexes **(72–74)** were synthesized with a yield of 69%–81% by cleaving the dinulcear precursor $[Rh(dpqx)_2Cl]_2$ in MeOH–CH_2Cl_2 mixture with sodium-2,4-pentanedionate/hfacac/Ph_2-acac, respectively, in the presence of nitrogen atmosphere for 8 h. Complexes **(72–74)** displayed ^{3}ILCT based (from phenyl moiety to quinoxaline unit of the dpqx ligand) bright ($\Phi_{PL} = 0.11\%-0.98\%$) orange-red phosphorescence ($\lambda_{em} = 598-612$ nm, $\tau_{PL} = 0.79-1.64$ μs) in dichloromethane mixed with ^{3}MLCT [dπ(Rh) $\rightarrow \pi^*$(dpqx)] photoluminescence at 298 K. The observation of a reduction in τ_{PL}

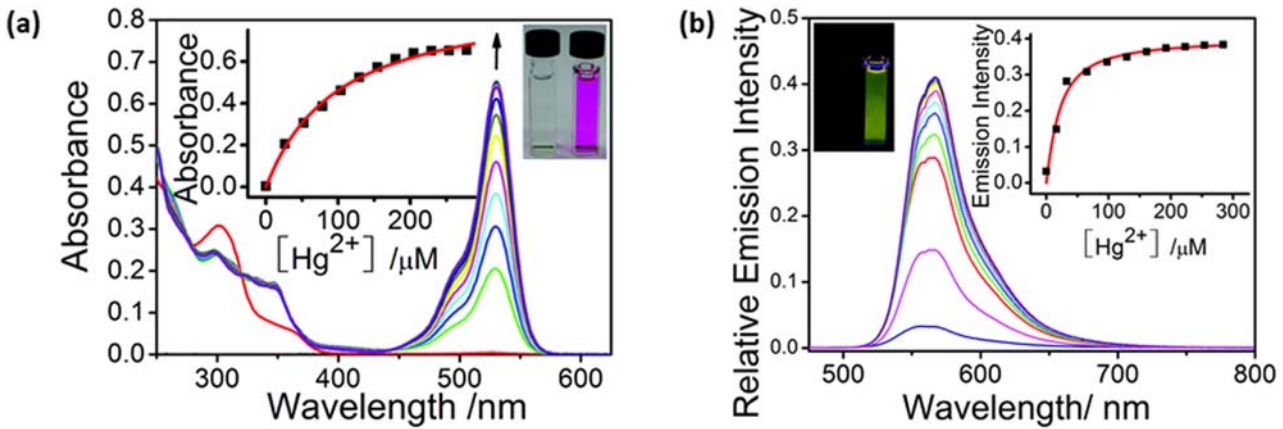

FIG. 8.7 (A) Changes in electronic absorption spectra of **(71)** in MeCN ([C] = 11.8 μM) at 298 K upon addition of varying concentrations of $[Hg]^{2+}$. Insets show the photograph of color changes and the plot of the absorbance at 530 nm as a function of the concentration of $[Hg]^{2+}$ with a theoretical fit and (B) changes in emission spectra of **(71)** in MeCN ([C] = 11.8 μM) at 298 K upon addition of varying concentrations of $[Hg]^{2+}$. Insets show the photograph of emission enhancement and the plots of the emission intensity at 560 nm as a function of the concentration of $[Hg]^{2+}$ with a theoretical fit. *Adapted from Wang, C., Lam, H.C., Zhu, N., Wong, K.M.C., 2015. Introduction of luminescent rhenium(I), ruthenium(II), iridium(III) and rhodium(III) systems into rhodamine-tethered ligands for the construction of bichromophoric chemosensors. FIG. 8.8 (A) Molecular structures of complexes **(72−74)**, (B) energy-level diagram of vacuum-deposited OLED, (C) electroluminescence spectra with different dopant concentrations (inset - photo of thin-film PL of **(74)** under UV irradiation), (D) EQEs with different hole-transporting layers and (E) the operational lifetime of the vacuum-deposited OLED was made with 5 v/v% of **(74)**. *Adapted from Wei, F., Lai, S.L., Zhao, S., Ng, M., Chan, M.Y., Yam, V.W.W., et al., 2019. Ligand mediated luminescence enhancement in cyclometalated rhodium(III) complexes and their applications in efficient organic light-emitting devices. J. Am. Chem. Soc. 141 (32), 12863−12871. With permission.*

values **(72)**, 0.08 μs; **(73)**, 0.65 μs; **(74)**, 0.22 μs in oxygenated compared to those in degassed solutions proved the triplet nature of the emissions in these complexes. The acac ligand influenced the dπ(Rh) orbital and the occurrence of very similar luminescence energy of **(72−74)** comprising of acac ligands with various substituents, [CH_3 **(72)**; CF_3 **(73)**; C_6H_5 **(74)**], showed the similar nature of phosphorescence in all the three complexes. Complexes **(72−74)** in doped *N,N*-dicarbazolyl-3,5-benzene (MCP) thin films exhibited intense ($\Phi_{PL} = 44\%-65\%$) orange-red phosphorescence ($\lambda_{em} = 597-603$ nm, $\tau_{PL} = 23-32$ μs). No observable luminescence quenching, as well as shift in luminescence peak maxima = were found in **(72−74)** upon increasing the doping concentration from 2 to 10 wt%, which indicated that no triplet-triplet annihilation and π-π interaction between the molecules at high doping concentration occurred. Complexes **(72−74)** were used for fabricating a solution-processed organic light emitting device (OLED). The solution-processed device possessed a structure of indium-tin-oxide (ITO)/poly(-ethylenedioxythiophene):poly(styrene sulfonic acid) (PEDOT:PSS) (40 nm)/ emissive layer (30 nm)/tris(2,4,6-trimethyl-3-(pyridine-3-yl)phenyl)borane (3TPyMB) (5 nm)/1,3,5-tri[(3-pyridyl)-phen-3-yl]benzene (TmPyPB) (40 nm)/LiF (1 nm)/Al (100 nm) with the emissive layer formed by spin-coating a solution of Rh(III):MCP in dichloromethane. The average current and external quantum efficiencies (C.E. and EQE) were found to be 5.0 cd/A and 3.2% with the optimized device (C.E. = 9.4 cd/A and EQE = 6.4%) made with 8 wt% of **(73)**, with CIE (x = 0.62, y = 0.38). Complex **(74)** was further used for vacuum-deposited OLED with a structure of ITO/molybdenum oxide (MoOx; 2 nm)/di-[4-(N,N-di-*p*-tolyl-amino)-phenyl]cyclohexane (TAPC) (40 nm)/4,4′,4″-tris(carbazol-9-yl)triphenylamine (TCTA)(5 nm)/x% rhodium(III):MCP (20 nm)/1,3,5-tris(6-(3-(pyridin-3-yl)phenyl)pyridine-2-yl)benzene (Tm3PyP26PyB) (50 nm)/LiF (1 nm)/Al (150 nm) (x = 2, 5, 8, 11 and 14 v/v%) (Fig. 8.8B and C). The maximum current efficiency of 9.9 cd/A and EQE of 7.0% were achieved for the 5 v/v% doped device. The device efficiency could be improved to 11.9 cd/A and 8.1%, when 3,3′-di(9*H*-carbazol-9-yl)biphenyl (mCBP) was used as the host. The current efficiencies and EQEs could be significantly boosted up to ~ 17.5 cd/A and ~ 12.2%, respectively, by either removing the hole-injecting MoOx or using a hole-transporting material (HTM) with lower hole mobility, i.e., *N,N′*-bis(naphthalene-1-yl)-*N,N′*-bis(phenyl)-2,2′-dimethyl-benzidine (α-NPD) or TCTA (Fig. 8.8D). The reduced hole-transport can result in a better balance in the hole and electron currents in the emissive layer and thus improved efficiency of device. Impressively, the device exhibited an operational half-lifetime (i.e., the time required for the luminance to drop to 50% of its initial value) ~ 946 h at 1000 cd/m^2 and over 3000 h at 100 cd/m^2 (Fig. 8.8E).

8.4 Luminescent Ir(II/III) complexes

8.4.1 Photophysical properties of polypyridyl Ir(III) complexes and their applications in solid-state lighting (OLED and LEC) devices

Flynn and Demas (1974) reported that a prototype Ir(III) complex $[Ir(bpy)_3]^{3+}$, **(75)**, synthesized by boiling a mixture of $K_3IrCl_6 \cdot 3H_2O$, $K_2S_2O_8$, $KHSO_4$ and 2,2′-bpy in water at 220−300°C. This complex exhibited blue-green emission ($\lambda_{em} = 440$ nm) with an associated τ_{PL}value of 2.4 μs in MeOH at 294 K (Demas et al., 1975). The complex exhibited $\pi \rightarrow \pi^*$ ligand based phosphorescence at 446 nm with τ_{PL} value of 80 μs at 77 K in MeOH−EtOH glass (Kahl et al., 1979). A triply ortho-metalated ppy complex [*fac*-$Ir(ppy)_3]^{3+}$, **(76)**, was synthesized with 45% yield upon refluxing $Ir(acac)_3$ and Hppy in degassed glycerol under nitrogen for 10 h at ~ 200°C (Dedeian et al., 1991). The complex **(76)** exhibited unstructured emission ($\lambda_{em} = 492$ nm) with associated τ_{PL} and Φ_{PL}values of 4.2 μs and 0.40 in 2-MeTHF at 298 K. The emission was attributed to the admixture of (^{3}LC + ^{3}MLCT) transitions (Tamayo et al., 2003). The complex **(76)** exhibited ^{3}MLCT based emission at 494 nm with an associated τ_{PL} of 5 μs and a Φ_{PL}value of 40 ± 10% in EtOH-MeOH glass at 77 K (in degassed toluene) Dedeian et al. (1991); King et al. (1985). Later, Tamayo et al. (2003) synthesized [*mer*-$Ir(ppy)_3]^{3+}$, **(77)**, by refluxing $[(ppy)_2IrCl]_2$, ppy and K_2CO_3 under an inert atmosphere in glycerol for 20−24 h at 140−150°C in a high yield of 75%. The complex **(77)** exhibited ^{3}MLCT based structured emission at 512 and 493 nm, respectively, with associated τ_{PL} and Φ_{PL} values of 0.15 μs (at 298 K), 4.2 μs (at 77 K) and ~ 4% (at 298 K), respectively. The lower quantum efficiencies of meridional than the facial complexes were due to the strong influence of the *trans* phenyl in the meridional isomers. Baldo et al. (1999) further used the complex **(76)** for the fabrication of vacuum-deposited OLED device (CIE x = 0.27, y = 0.63, Fig. 8.9A). The device displayed peak EQE and power efficiencies of 8.0% (28 cd/A) and 31 lm/W, respectively, due to a shorter triplet lifetime and reasonable photoluminescent efficiency. At an employed voltage of 4.3 V with 6% of **(76)** in 4,4′-bis(*N*-carbazolyl)-1,1′-biphenyl (CBP), the luminance reached at 100 cd/m^2 with EQE and power efficiencies (P.E.s) as 7.5% (at 26 cd/A) and 19 lm/W, respectively. High internal efficiency was observed due to the effective transmission of both; singlet and triplet excited states in the host CBP to $Ir(ppy)_3$, associated with a short phosphorescent decay of $Ir(ppy)_3$ (< 1 μs) that reduced the saturation of the phosphor at high drive currents, affording a peak luminance of 100,000 cd/m^2.

Lanansky et al. (2001) reported the synthesis and photophysical studies of cyclometalated Ir(III) complexes such as $[(ppy)_2Ir(acac)]$, **(78)**, $[(bt)_2Ir(acac)]$, **(79)** and $[(btp)_2Ir(acac)]$, **(80)**, [bt = 2-phenylbenzothiozolato-C^2,N'), btp = 2-(2′-benzothienyl)-pyridinato- C^3,N')]. The complexes were synthesized with a

yield of 75%–90% by refluxing chloro-bridged Ir(III)-dimer, $C\hat{}N_2Ir(\mu\text{-}Cl)_2IrC\hat{}N_2$($C\hat{}N$ = ppy, bt, btp), acac and Na_2CO_3 in an inert atmosphere in 2-ethoxyethanol for 12–15 h. Complexes **(78–80)** in 2-MeTHF exhibited unstructured ^{3}MLCT and structured $^3(\pi\text{-}\pi^*)$ C^N based luminescence centered at 516, 557, 612 nm (τ_{PL} and Φ_{PL} = 1.6 μs and 34% **(78)**, 1.8 μs and 26% **(79)**, 5.8 μs and 21% **(80)**) at 298 K. The OLEDs structure used for the complexes **(78–80)** (7 wt% in CBP) was the same as was formerly established for *fac*-Ir(*ppy*)$_3$-based OLEDs (Fig. 8.9B) (Baldo et al., 1999). The OLEDs with very similar current-voltage characteristic displayed green **(78)**, (CIE x = 0.31, y = 0.64), yellow **(79)**, (CIE x = 0.51, y = 0.49) and red electroluminescence **(80)**, CIE (x = 0.68, y = 0.33). The OLEDs based on **(78)**, **(79)** and **(80)** showed the EQEs of 12.3% (at 0.01 mA/cm^2), 9.7% (at 1 mA/cm^2) and 6.6% (at 1 mA/cm^2) with associated P.E.s of 38, 11 and 2.2 lm/W, respectively. These high efficiencies were due to efficient trapping and radiative relaxation of the singlet and triplet excitons formed in the electroluminescent process. The complex **(78)** was further studied with various doping concentrations to afford a change in the EQE, e.g., on lowering the concentration of **(78)** from 7% to 4% in CBP, the EQE increased from 9.5% to 11.9% whereas on increasing the concentration to 100%, the efficiency dropped to 1.5%, due to enhanced self-quenching in the neat film of **(78)** (Fig. 8.9C). The performances of OLEDs (EQEs, P.E.s, etc.) of **(78–80)** were found to be in the same trend as the photoluminescence quantum efficiencies of **(78–80)**.

Archetype ionic transition-metal complexes (iTMCs) [Ir(ppy)$_2$(bpy)]PF$_6$, **(81)** and [Ir(ppy$_)_2$(phen)]PF$_6$, **(82)** used by Costa et al. (2009) as the primary active components in light-emitting electrochemical cells (LECs). The complexes **(81)** and **(82)** were synthesized by the traditional way of cleaving the chloro-bridged Ir(III) dimer in presence of an ancillary ligand. These complexes **(81)** and **(82)** exhibited an admixture of ^{3}MLCT + ^{3}LLCT based unstructured emissions at 585 nm (τ_{PL} = 0.43 μs, Φ_{PL} = 14%) and 530 nm (τ_{PL} = 1.29 μs, Φ_{PL} = 17%), respectively, in deaerated MeCN at 298 K. The iTMCs exhibited similar nature of emission, as described earlier, at 590 nm (Φ_{PL} = 66%) (for **81**) and 578 nm (Φ_{PL} = 71%) (for **82**) with 5 wt% doped film in poly(methylmethacrylate) (PMMA). The higher observed Φ_{PL} value of iTMC **(82)** compared to that of **(81)** was due to the lower degree of non-radiative deactivation through the closely lying ^{3}MC state to the emitting state in the later. The iTMCs **(81)** and **(82)** were used as the single active components in double-layer LECs. The LECs fabricated possessed a structure of indium-tin-oxide (ITO)/poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT:PSS) (100 nm)/Ir-iTMCs (80 nm)/Al (80 nm). At an applied voltage of 3 V, The LEC using complex **(81)** showed a high luminance (219 cd/m^2) with a higher stability (t = 668 h, total photon flux = 6.61 J, EQE (neat film) = 2.1%, CIE x = 0.5078, y = 0.4859) with turn-on time much lower (t_{ON} = 70.2 h) than the device comprising of **(82)** (t_{ON} = 160 h, luminance = 40 cd/m^2, t = 567 h, total photon flux = 2.42 J, EQE (neat film) =

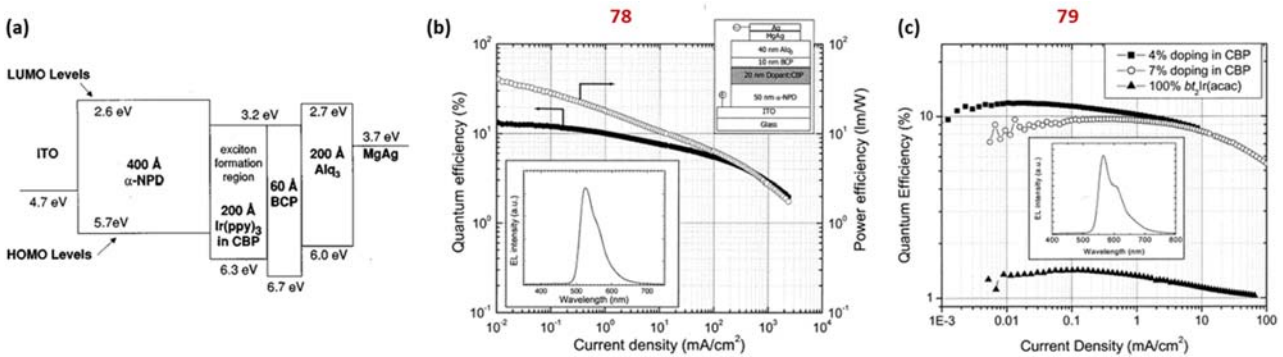

FIG. 8.9 (A) Energy-level diagram of vacuum-deposited OLED of complex **(77)** and (B) EQE and P.E. of vacuum-deposited OLED of complex **(78)** (the inset at the top and bottom shows the energy level structure OLEDs of **(78–80)** and PL spectra of complex **(79)**, respectively) and (C) EQE and P.E.s ofvacuum-deposited OLEDs of complex **(79)** with different doping concentration (the inset shows the PL spectra of complex **(79)**. *(A) Adapted from Baldo, M.A., Lamansky, S., Burrows, P.E., Thompson, M.E., Forrest, S.R., 1999. Very high-efficiency green organic light-emitting devices based on electrophosphorescence. Appl. Phys. Lett. 75 (1), 4–6. With Permission. (C) Adapted from Lamansky, S., Djurovich, P., Murphy, D., Abdel-Razzaq, F., Lee, H.E., Adachi, C. et al., 2001. Highly phosphorescent bis-cyclometalated iridium complexes: synthesis, photophysical characterization and use in organic light emitting diodes. J. Am. Chem. Soc. 123 (18), 4304–4312, With permission.*

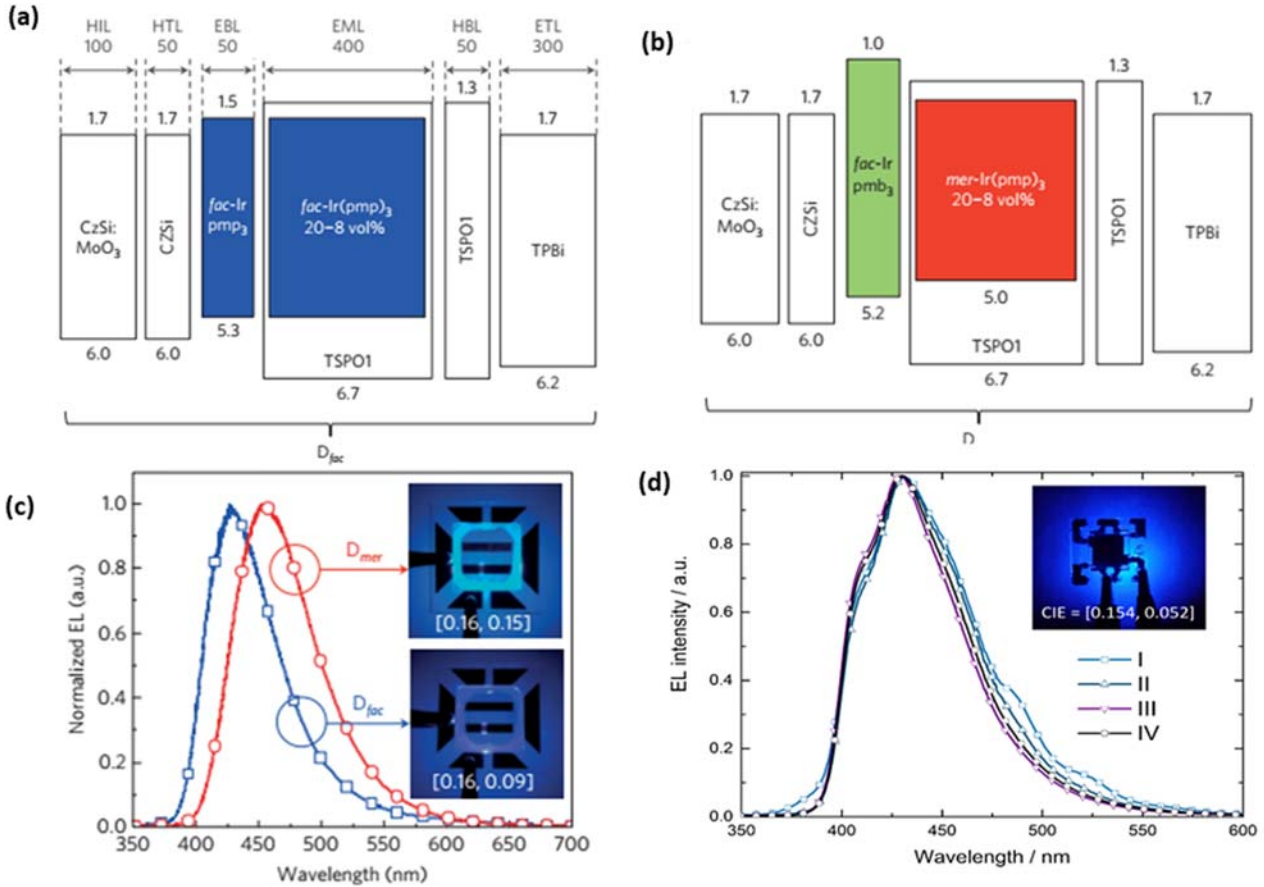
1.5, CIE x = 0.5174, y = 0.4824) which indicated that device having complex **(81)** had better performance. This poor performance of **(82)** as compared to **(81)** was the result of closely lying triplet states T_1 and T_2 ($\Delta E_{T1\text{-}T2} = 0.23$ eV) in **(82)** owing to the near degeneracy of the LUMO and LUMO + 1 located on the phen ligand whereas in **(81)** lowest triplet states were well separated and emission took place from T_1 independently of the medium. This fact also resulted in the red-shift of the EL maximum by 48 nm compared to the PL maximum of iTMC **(82)**, whereas the PL and EL maxima of iTMC **(81)** appeared at similar energies. The performance of the devices dramatically improved when small amounts of ionic liquid (IL = 1-butyl-3-methylimidazolium hexafluorophosphate) were added to the Ir-iTMC; the turn-on time improved drastically (from hours to minutes) and the device current and power efficiencies increased by almost one order of magnitude. However, the improvement of the turn-on time was accompanied by a decrease in the stability of the device from 700 h to a few hours ($t_{ON} = 7.2$ h, luminance = 334 cd/m^2, $t_{1/2} = 69$ h, EQE = 3.0% for **(81)** and $t_{ON} = 6.4$ h, luminance = 63 cd/m^2, $t_{1/2} = 73$ h, EQE = 2.1% for **(82)**; $t_{1/2}$ is the time from voltage turn-on to the time where the luminance is half of the maximum value).

Blue phosphorescent OLEDs with tris-cyclometalated iridium complex [*fac*-Ir(mpim)$_3$], (where mpim = mesityl-2-phenyl-1H-imidazole) doped in different hosts, e.g., 2,6-bis(3-(carbazol-9-yl)phenyl)pyridine (26DCzPPy) and TCTA were also reported (Udagawa et al., 2014). The photo luminescent quantum efficiency (Φ_{PL}) of solid-state films comprising TCTA/10 wt% *fac*-Ir(mpim)$_3$ **(83)** and 26DCzPPy/10 wt% *fac*-Ir(mpim)$_3$, **(84)** were found to be 61% **(83)** and 62% **(84)**, the films exhibiting single exponential decay with $\tau_{PL} = 1.50$ (for **83**) and $\tau_{PL} = 1.55$ μs (for **84**). Two different host materials, e.g., 26DCzPPy or TCTA were used in the devices. These blue OLEDs (CIE x = 0.18, y = 0.41) possessed a common structure as ITO (90 nm)/1,4,5,8,9,11-hexaazatriphenylenehexacarbonitrile (HATCN) (5 nm)/TAPC (35 nm)/10 wt% *fac*-Ir(mpim)$_3$-doped host (10 nm)/Tm4PyPB (50 nm)/liq (2 nm)/Al (80 nm). With an extremely low operating voltage of 3.06 V at 100 cd/m^2, a TCTA-based OLED exhibited P.E. = 51.7 lm/W, C.E. = 50.3 cd/A and EQE = 22.8%. With lower driving voltage, TCTA (5 nm)/10wt% *fac*-Ir(mpim)$_3$-doped TCTA (5 nm) device displayed higher P.E., EQE and much higher current density due to a lower hole-injection barrier from TAPC to TCTA. At a driving voltage of 3.22 at 100 cd/m^2, the 26DCzPPy-based OLED showed highest performance with P.E. = 71.9 lm/W, C.E. = 73.6 cd/A and EQE = 33.2% due to the hole trapping property of [*fac*-Ir(mpim)$_3$]. A combination of two hosts, TCTA/26DCzPPy in another device was used, which had two advantages for which it reduced the driving voltage as (i) TCTA can enhance the hole injection from TAPC and (ii) 26DCzPPy can promote the electron injection from Tm4PyPB. The TCTA/26DCzPPy-based OLED showed P.E. = 72.5 lm/W, C.E. = 67.4 cd/A and EQE = 30.7% at 100 cd/m^2,



with an extremely low driving voltage of 2.92 V. Since the blue device with Tm4PyPB didn't show both high EQE of 30% and high P.E. over 70 lm/W and therefore, in a new blue device, ETL was changed from Tm4PyPB to B_3PyPB. The device showed P.E. = 75.6 L m/W, C.E. = 73.2 cd/A, EQE = 29.6% without any light-outcoupling enhancement at a driving voltage of 3.04 V at 100 cd/m^2.

Sajjad et al. (2016) synthesized interesting blue-green cationic Ir(III) complexes $[Ir(ppy)_2(Me\text{-}gpy)]PF_6$, **(85)**, $[Ir(dFppy)_2(CF_3\text{-}gpy)]PF_6$, **86**, $[Ir(dFppy)_2(Me\text{-}gpy)]PF_6$, **(87)**, (where Me-gpy = 2,3,4,6,7,8-Hexahydro-1-(5-methylpyridin-2-yl)-pyrimido[1,2-a]pyrimidine and CF_3-gpy = 1-(5-(trifluoromethyl)pyridin-2-yl)-2,3,4,6,7,8-hexahydro-pyrimido-[1,2-a]pyrimidine, dFppy = 2-(4,6-diflurophenyl)pyrdinato). The complexes were synthesized by heating the suspension of degassed mixture of $[Ir(C^{\wedge}N)_2Cl]_2$ and the gpy-CF_3/gpy-Me ligand in DCM:MeOH (1:1, v/v) in 71−81%. Complexes **(85−87)** in MeCN in a degassed solution exhibited ^{3}LC and ^{3}CT based emissions centered at 510 nm ($\tau_{PL} = 1.90\ \mu s$, $\Phi_{PL} = 50.8 \pm 4.0\%$ for **85**), 462 nm ($\tau_{PL} = 0.11$ and 0.98 μs, $\Phi_{PL} = 1.7 \pm 0.2\%$ for **86**), 470 nm ($\tau_{PL} = 2.60\ \mu s$, $\Phi_{PL} = 65.6 \pm 5.0\%$ for **87**). The 2 wt% **(85)** in PMMA thin film showed Φ_{PL} of 65.9% and 72.4% in air and vacuum, respectively, at 300 K. Complexes **(85−87)** fabricated as solution-processed OLEDs comprised of structure ITO/PEDOT:PSS (30 nm)/PVK (30 nm)/mCP:OXD7 (2,2′-(1,2-phenylene)bis[5-(4-*tert*-butylphenyl)-1,3,4-oxadiazole]: **(85−87)** (75:20:5wt%) (30 nm)/B_3PYMPM (60 nm)/Ca (20 nm)/Al (100 nm). EL spectra of **(85−87)** are similar to their PL spectra but these were red-shifted and displayed different relative intensities of the vibronic peaks. The OLEDs at 100 cd/m^2 showed the EQEs and C.E. of 6.3%, 20.8 cd/A (CIE x = 0.29, y = 0.58 for **85**), 2.3%, 6.2 cd/A (CIE x = 0.26, y = 0.47 for **87**) and 2.8%, 7.1 cd/A (CIE x = 0.22, y = 0.43 for **86**) with associated P.E.s of 8.7, 1.9 and 1.6 lm/W, respectively. Complex **(87)** showed the best performing OLED with low turn-on voltage ($V_{ON} = 5.8$) based on the use of cationic iridium complexes as emissive layer attributed to the shallower HOMO enabling more effective hole injection, which explained the low-turn on voltage and enhanced device efficiency and charge balance. Subsequently, the same group synthesized another four cationic Ir(III) complexes $[Ir(2\text{-}TFMePpy)_2(dtBubpy)]PF_6$, **(88)**, $[Ir(2\text{-}TFMyPy)_2(dtBubpy)]PF_6$, **(89)**, $[Ir(2\text{-}TFMtPpy)_2(dtBubpy)]PF_6$, **(90)**, $[Ir(2\text{-}TFMsPpy)_2(dtBubpy)]PF_6$, **(91)**, (where2-TFMePpy = 2-(4-(trifluoromethyl) phenyl)-pyridine, 2-TFMyPpy = 2-(4-(trifluoromethoxy)phenyl)pyridine, 2-TFMtPpy = 2-(4-((trifluoromethyl)thio)phenyl)pyridine, 2-TFMsPpy = 2-(4-((trifluoromethyl)sulfonyl)phenyl)pyridine) in high yields of 70%−86% (Pal et al., 2016). At RT ($\lambda_{exc} = 360$ nm) complexes **(88−91)** in degassed MeCN displayed mixed structured/unstructured ^{3}LC + (^{3}MLCT/^{3}LLCT) structured transition centered at 484 nm ($\tau_{PL} = 1.79\ \mu s$, $\Phi_{PL} = 45\%$ for **88**), 527 nm ($\tau_{PL} = 1.14\ \mu s$, $\Phi_{PL} = 50\%$ for **89**), 491 nm ($\tau_{PL} = 3.31\ \mu s$, $\Phi_{PL} = 66\%$ for **90**) and 515 nm ($\tau_{PL} = 4.28\ \mu s$, $\Phi_{PL} = 55\%$ for **91**). Complex **(91)** with the

strongest electron withdrawing (EWG) group $-SO_2CF_3$ exhibited red-shifted emission whereas complex with $-CF_3$ displayed the most blue-shifted emission. The thin film PL of complexes (**88**−**91**) showed the similar trend as observed for the solution photoluminescence. Single layer LECs were fabricated with a general structure ITO/PEDOT:PSS/[Bmim][PF_6]:emitter (4:1 M ratio)/Al with complexes (**88**−**91**) acting as the emitters (Bmim = 1-butyl-3-methylimidazolium hexafluorophosphate). All the EL maxima were found to be red-shifted with respect to the thin film maxima though the position of shoulder in complexes (**88**) and (**90**) remained at the same energy. The red-shift of the EL and thin-film PL maxima in solution was found to be due to the aggregation in the solid state. The operating voltage of LECs (**88**−**90**) at 50 A/m^2 displayed sky-blue to green (CIE x = 0.37−0.45, y ∼ 0.54) and reached a steady-state value at 2.80−3.00 V, demonstrating no charge injection barrier. At current density of 100 A/m^2, the LECs displayed EQE = 3.0%, C.E. = 9.8 Cd/A, luminance = 987 Cd/m^2 (for **88**), EQE = 2.3%, C.E. = 7.3 Cd/A, luminance = 726 Cd/m^2 (for **89**), EQE = 1.1%, C.E. = 3.5 Cd/A, luminance = 350 Cd/m^2 (for **90**). Complex (**91**) with an irreversible reduction potential only achieved a very low level of luminance (32 Cd/m^2). In the subsequent year, Pal et al. (2017) also reported red-to-NIR cationic Ir(III) complexes, [Ir(ppy)$_2$(Btz)]PF_6, (**92**) and [Ir(ppy)$_2$(Bbtz)]PF_6, (**93**), (Btz = 2,2′-bithiazole, Bbtz = 2,2′-Bibenzo[d]thiazole) in excellent yield (91%−95%) and used them in red-to-NIR LECs. In degassed MeCN at 298 K, complexes (**92**) and (**93**) exhibited featureless ^{3}CT emission at 658 nm ($\tau_{PL} = 0.08$ μs, $\Phi_{PL} = 1.72\%$ for **92**) and 744 nm ($\tau_{PL} = 0.044$ μs, $\Phi_{PL} = 0.35\%$ for **93**). At an excitation value of 320 nm, the thin films of complexes (**92**) and (**93**) mixed with [Bmim][PF_6] exhibited featureless ^{3}CT emission at 658 nm ($\tau_{PL} = 257$ ns, $\Phi_{PL} = 14\%$ for **92**) and 707 nm ($\tau_{PL} = 117$ ns, $\Phi_{PL} = 5\%$ for **94**). The LECs of complexes (**92**) and (**93**) possessed a structure of ITO/PEDOT:PSS/Ir-iTMCs:[Bmim][PF_6] (4:1 molar ratio)/Al LEC based device of complexes (**92**) and (**93**) exhibited EL at 661 and 705 nm, respectively. The efficiency of LEC-(**92**) was more strongly affected by increased in the current density. LEC-(**92**) showed an EQE of 0.23% ($t_{1/2} = 0.24$ h) and 0.13% ($t_{1/2} = 0.15$ h) and LEC-(**93**) showed an EQE of 0.37% ($t_{1/2} = 80$ h) and 0.33% ($t_{1/2} > 80$ h) at current densities of 400 and 800 A/m^2, respectively. The higher $t_{1/2}$ value for LEC-(**93**) in comparison to the same of LEC-(**92**) was assigned to the presence of the annulated benzenes in the ancillary ligand.

Ir(III) complexes were also synthesized with *N*-heterocyclic carbene such as [*fac*-Ir(pmp)$_3$], (**94**) and [*mer*-Ir(pmp)$_3$], (**95**), (where pmp = *N*-Phenyl-*N*-methyl-pyridoimidazol-2-yl) (Lee et al., 2016). This unique work dealt with Ir−NHC complexes, which can act as both: a deep blue emissive layer (EML) as well as efficient hole-conducting electron blocking layer (EBL). The complexes showed ^{3}LC/^{3}MLCT based broad emission at 418 nm ($\tau_{PL} = 1.2 \pm 0.1$ μs, $\Phi_{PL} = 76 \pm 5\%$ (for **94**)) and at 465 nm

($\tau_{PL} = 0.8 \pm 0.1$ μs, $\Phi_{PL} = 78 \pm 5\%$ (for **95**)) in deaerated 2-MeTHF at 295 K. The PL spectrum of **(95)** was found to be broader and red-shifted compared to that of **(94)** due to stabilized excited states of **(95)**. Complexes **(94)** and **(95)** were used in fabricating two Phosphorescent Organic Light-Emitting Diodes (PHOLEDs) (Fig. 8.10A and B). The electron blocking layer (EBL) consisted of **(94)** (when **94** was also used in EML) and [*fac*-Ir(pmb)$_3$] (when **95** was also used in EML) (pmb = *N*-Phenyl-*N*-methyl-benzimidazol-2-yl), which had either equal or shallower LUMO energies than that of the host, as well as equal or larger triplet energy levels than the dopants ($E_T = 2.90$ eV). This empowered effective hole injection into the hole-conducting dopants through blocking electrons transported by the host. At a 20 vol% doping concentration near the EBL/EML interface, it enabled hole injection and transport, which decreased gradually at the EML/HBL interface at 8 vol% dopant concentrations. At 10 mA cm^{-2}, complex **(94)** based PHOLED showed EQE = 9.0 ± 0.1 (at 1000 cd/m^2), luminance = 7800 ± 400 cd/m^2 (at $J_{1/2}$), CIE x = 0.16, y = 0.09 whereas **(95)** based PHOLED showed EQE = 13.3 ± 0.1 (at 1000 cd/m^2), luminance = $22{,}000 \pm 1000$ cd/m^2 (at $J_{1/2}$), CIE x = 0.16, y = 0.15 (Fig. 8.10C). The difference in EQE values was assigned to (i) different degrees of aggregation-induced quenching, which in turn were induced due to their different static dipole moments (17.2 D for **(94)** and 10.8 D for **(95)** and (ii) lower absorptivity of **(95)** leading to the higher fraction of host quenching. Later, Pal et al. (2018a) reported two deep blue-emitting homoleptic Ir(III) complexes *mer*-Ir(3-TFpIm)$_3$, **(96)** and *mer*-Ir(4-TFpIm)$_3$, **(97)**, (where (3/4-TFpIm)$_3$ = 3-methyl-1-(3/4-(trifluoromethyl)phenyl)-1*H*-3λ^4-imidazole). Complexes **(96)** and **(97)** exhibited admixture of ^{3}LC + ^{3}MLCT based deep blue structured emission at 424 nm ($\tau_{PL} = 280$ μs (65%), 1816 μs (35%), $\Phi_{PL} = 25\%$ (for **96**)) and λ_{em} at 427 nm ($\tau_{PL} = 698$ μs (48%), 1820 μs (52%), $\Phi_{PL} = 72\%$ (for **97**)) in deaerated CH_2Cl_2 at 298 K. Complexes **(96)** and **(97)** also showed structured emission at 409 nm ($\tau_{PL} = 2167$ μs, $\Phi_{PL} = 13.7\%$ (N_2), 13.5% (air) (for **96**)) and λ_{em} at 428 nm ($\tau_{PL} = 3993$ μs, $\Phi_{PL} = 46.6\%$ (N_2), 38.6% (air) (for **97**)) in 10 wt% doped PMMA film. Complexes **(96)** and **(97)** were used in fabricating vacuum-deposited OLEDs where **(97)** was used as the emitter and **(96)** was used as the EBL due to its high triplet energy ($E_T = 3.19$ eV at 77 K) and shallow LUMO level. The high emission energy of **(97)** restricted the choice of the host material. Apart from three OLED devices (devices I-III) reported in this work that included different HTL, exciton blocking layers, the best OLED performance came from minimum possible interlayered-device, device IV, (TAPC as HTL, **(96)** as EBL, 10 wt% **(97)** in DPEPO as EML and TPBi as ETL (DPEPO = (Bis [2-(diphenylphosphino) phenyl] ether oxide), TPBi = 1,3,5-tris(1-phenyl-1H-benzimidazol-2-yl)benzene). DPEPO was used because of its wide band gap and high triplet energy, which was higher than the triplet energy of **(97)** ($E_T = 3.31$ eV). On comparing the emission spectra of **(97)** in DPEPO with

HIL = hole injecting layer, HTL = hole transporting layer, EBL = electron blocking layer, EML = emissive layer, HBL = hole blocking layer, ETL = electron transporting layer CzSi = 9-(4-*tert*-butylphenyl)-3,6-bis(triphenylsilyl)-9H-carbazole, TSPO1 = diphenyl-4-triphenylsilylphenylphosphine oxide, TPBi = 1,3,5-tris(1-phenyl-1H-benimidazole-2-yl)benzene.

emission spectra observed in thin films, it was found that in DPEPO, emission was narrower and had lower Φ_{PL}, which was assigned to the different polarity of the surrounding host medium and guest-host interactions that affect the nature of the excited state. These devices exhibited electroluminescence at 430−431 nm with associated FWHM = 62−68 nm, EQE from 7.2% to 13.4%, P.E. = 2.80−3.95 and CIE x = 0.151−0.156, y = 0.052−0.077 (Fig. 8.10D). Device IV displayed the bluest and best performance with max EQE and P.E. values at 13.4% and 3.50 lm/W, respectively, whereas at 100 cd/m^2 this device showed EQE and P.E. values at 12.5% and 2.98 lm/W, respectively. Optical anisotropy of the DPEPO:**97** film was studied with variable spectroscopic ellipsometryto optimize the device performance and to evaluate the emitter arrangement. A value of S (order parameter) of −0.26 was found, which corresponded to the fact that a majority of transition dipole moments were lying horizontal to the substrate plane.

Tokito et al. (2003) reported the fabrication of OLEDs of an interesting Ir(III) complex, bis[(4,6-di-fluorophenyl)-pyridinato-C^2,N']picolinate iridium(III), **(98)**, also commercially known as FIrpic. The complex was synthesized by the heterolytic cleavage of FIr_2Cl_2 with picolinic acid (Fig. 8.11A) (Yen et al., 2005). The OLED devices of complex **(98)** with CBP (E_T = 2.6 eV at 77 K) and 4,4′-bis(9-carbazolyl)2,2′-dimethyl-phenyl (CDBP) (E_T = 3.0 eV at 77 K) as host materials were fabricated as ITO (200 nm)/PEDOT:PSS (40 nm)/α-NPD (30 nm)/(CDBP or CBP):FIrpic (40 nm, 3%)/bis(2-methyl-8-quinolinato)-4-phenylphenolatealuminum(III) (BAlq) (30 nm)/LiF (1 nm)/Al (150 nm). The OLED of complex **(98)** with CDBP as host material showed an EQE = 10.4% (at 20.5 cd/A), P.E. = 10.5 lm/W and C.E. = 20.4 cd/A which was found to be greater than the CBP based OLED device having EQE = 5.1% (Fig. 8.11B). In both; CBP and CDBP based OLEDs, EQE decreased at a high current density, which was assigned to triplet-triplet annihilation. The high efficiency in the CDBP based device was due to the alignments of the triplet energies of the organic materials comprised in the devices. As CDBP has E_T = 3.00 eV, which was higher than the E_T of FIrpic (2.70 eV) and therefore, the transfer of triplet energy from FIrpic to CDBP was

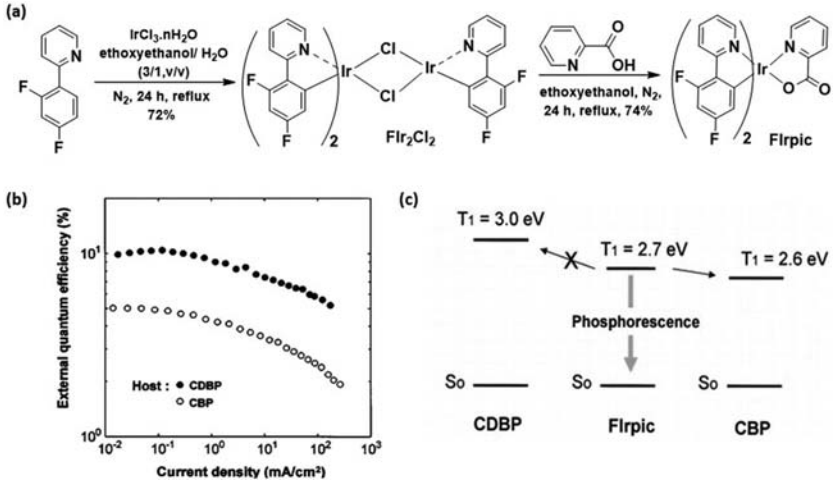

FIG. 8.11 (A) Synthesis of FIrpic, (B) EQE *vs* current density for OLEDs with CBP and CDBP as host materials and (C) E_T alignment of FIrpic, CBP and CDBP. *Adapted from Tokito, S., Iijima, T., Suzuri, Y., Kita, H., Tsuzuki, T., Sato, F., 2003. Confinement of triplet energy on phosphorescent molecules for highly-efficientorganic blue-light-emitting devices. Appl. Phys. Lett. 83 (3), 569–571. With Permission.*

suppressed and energy-restricted on the FIrpic, which led to high phosphorescence from FIrpic triplet in the device (Fig. 8.11C). Yeh et al. (2005) reported two OLED devices with new host materials, e.g., 1,3-bis(9-carbazolyl) benzene (mCP) and 3,5-bis(9-carbazolyl)tetraphenylsilane (SimCP). The OLED comprised of structure as ITO/*N*,*N*′-di(naphthalene-1-yl)-*N*,*N*′-diphenylbenzidine (NPB) (30 nm)/SimCP:dopant (30 nm, 7%)/2,2′,2″-(1,3,5-phenylene)tris(1-phenyl-1*H*-benzimidazole) (TPBI) (30 nm)/LiF/Al. Although having the same E_T value of 2.9 eV, the SimCP based OLED showed a better EQE of 14.4% as compared to that of mCP based OLED (EQE = 12.3%) with a P.E. = 11.9 lm/W. This fact was attributed to the rigidity of the triphenylsilyl structural moiety that brought more balanced electron and hole combination in the host matrix of the SimCP or by alleviating the T_1-T_1 annihilation, concluding that the host material played an important role for the EQE of the OLEDs.

8.4.2 Application of Ir(III) complexes in photoredox catalysis

Ir(III) complex, $[Ir(ppy)_2(dtbbpy)]PF_6$, (dtbbpy = 4,4′-di-tert-butyl-2,2′-bipyridine), **(99)**, was used for the oxidative coupling of nitroalkanes and tertiary *N*-arylamines *via* visible-light photoredox catalysis by Condie et al. (2010). A variety of *N*-aryltetrahydroisoquinolines was subjected to the optimized conditions by aza-Henry reaction with 1 mol% of **(99)** and visible light

that showed high yields of the coupling products in 92–96% (Fig. 8.12A–Entries 1–3). The light and PRC were found to be the basic requirements for the reaction to give the desired yield of the product. When the reaction was conducted in the dark, the substrate did not display any conversion (Fig. 8.12A–Entry 1-substrate 3). In the absence of catalyst, the substrate took 180 h for the 83% conversion of the reaction (Fig. 8.12A–Entry 1-substrate 4). The non-benzylic amine afforded the desired coupling in a moderate yield of 27% (Fig. 8.12A–Entry 2). The use of a less volatile nitro compound, $PhCH_2NO_2$ in DMF, in the presence of **(99)** resulted in the full conversion of the substrate (Fig. 8.12A–Entry 3). After degassing, the same reaction took 72 h with the attenuated rate for the clean formation of the product. The use of this less volatile nitro compound provided evidence for the proposed mechanism as shown (Fig. 8.12B). Upon excitation, the Ir(III)* reductively quenched the amine to give rise to radical iminium cation. The so generated powerful reducing agent Ir(II) [Ir(III)/Ir(II) = −1.51 V *vs* SCE] reduced oxygen to produce an oxygen radical anion, which in turn abstracted a hydrogen atom from the trialkylammonium radical cation to form the iminium ion. This ion reacted with the nitroalkane to afford the desired product. Nguyen et al. (2011) reported an Ir(III) complex, $[Ir\{dF(CF_3)ppy\}_2(dtbbpy)]PF_6$, **(100)**, for the intermolecular Atom Transfer Radical Addition (ATRA) to olefins. The reaction of tosylated allylamine and diethyl 2-bromomalonate (DBM) in DMF in the presence of **(100)** for 24 h resulted in the first intermolecular ATRA in a 17% yield. Optimization of the reaction with LiBr as an additive and H_2O as a co-solvent led to an increase in the yield from 45% to 67%. Later, the reaction was performed with BOC-protected (BOC = *tert*-Butyloxycarbonyl protecting group) allylamine and 5-hexen-1-ol, which afforded more consumption of the substrate and resulted in a high yield of the product up to 99%. The light and PRC were found to be the basic requirements for the reaction to give the desired yield of the product, e.g., using substrate 5-hexen-1-ol, no reaction took place without the presence of light and PRC. The atom transfer of various functional groups including free alcohols, silyloxyethers, benzylethers, alkylbromides, esters, enones, carbamates and aromatic rings were well tolerated with optimized conditions. The achievement of the intermolecular atom transfer with DBM encouraged the investigation of the other compounds comprising of activated C-X bonds (Fig. 8.12C– Entries 1–2). It was found that hexene did not undergo coupling with DBM but it resulted in effectual ATRA with ethyl bromodifluoroacetate (Fig. 8.12C–Entry 2). The dehydroiodination of the atom transfer products with CF_3I, comprehended by subjecting the ATRA product to diazabicycloundecene (DBU) in toluene, resulted in the formation of the trifluoromethylalkene (Fig. 8.12C– Entry 3). In addition, 1,1-cyclopropane diesters were generated in an excellent yield (Fig. 8.12C – Entry 4). It was concluded that only 0.01 mol% of **(100)** was required for the 97% yield that resulted from the coupling reaction of DBM with 5-hexen-1-ol. In the mechanism, upon excitation, oxidative quenching of

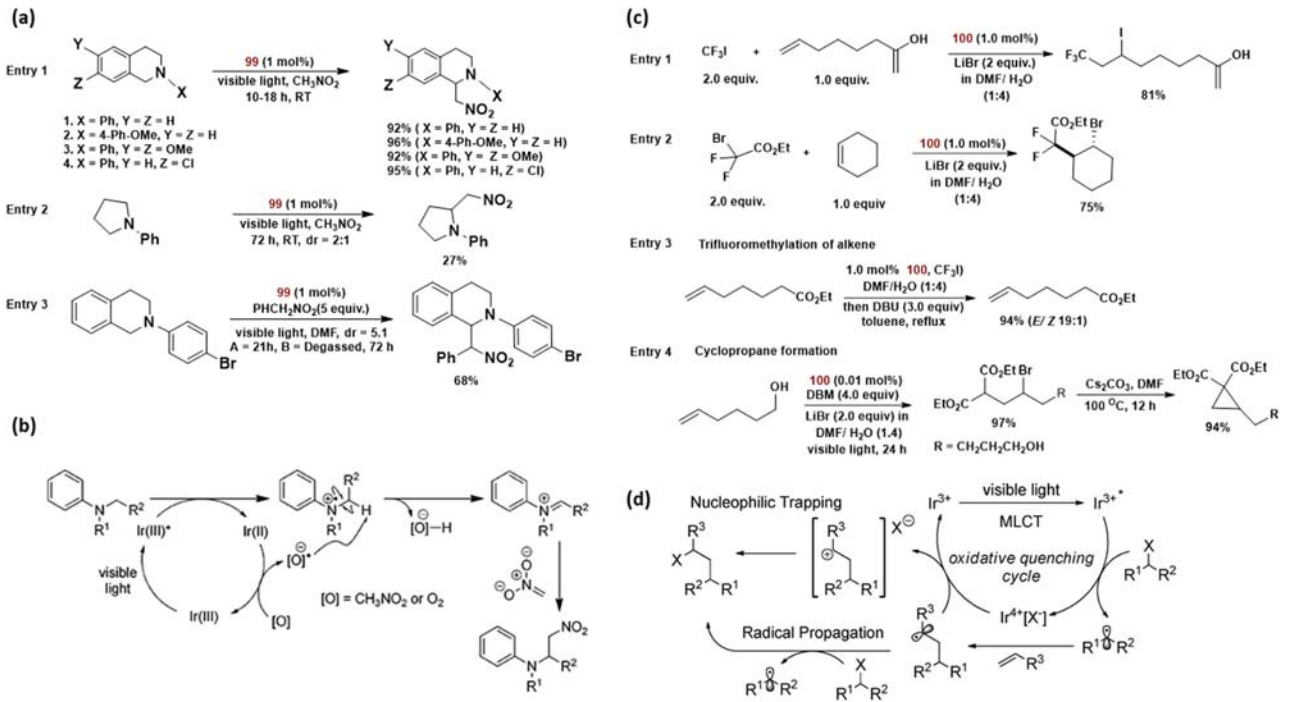

FIG. 8.12 (A) Examples of oxidative aza-Henry reactions using PRC, (B) mechanism of iminium ion generation using photoredox catalysis, (C) examples of ATRA reactions using PRC and, (D) proposed mechanism of an ATRA reaction. *(B) Adapted from Condie, A.G., González-Gómez, J.C., Stephenson, C.R.J., 2010. Visible-Light photoredox catalysis: aza-Henry reactions via C−H functionalization. J. Am. Chem. Soc. 132 (5), 1464−1465. With Permission; (D) Adapted from Nguyen, J.D., Tucker, J.W., Konieczynska, M.D., Stephenson, C.R.J., 2011. Intermolecular atom transfer radical addition to olefins mediated by oxidative quenching of photoredox catalysts. J. Am. Chem. Soc. 133 (12), 4160−4163. With Permission.*

the visible-light-induced Ir(III)* by the haloalkane and α-halocarbonyl took place, which generated an electrophile radical along with the Ir(IV) complex, with halide as the counter ion (Fig. 8.12D). The halide then resulted in the addition to the olefin. The ATRA product can be generated by two potential pathways. First, the oxidation of the alkyl radical (0.47 V *vs* SCE) by Ir(IV) generated the carbocation pre-associated with the halide, which in turn combined with the halide to afford the final product selectively.

MacMillan et al. (2011) investigated photoredox catalyzed C−H arylation reactions of cyclicbenzylic amines using Ir(III) complex, [*fac*-Ir(ppy)$_3$], **(76)**. The reaction of *N*,*N*-alkyl/cyclic amine and 1,4-dicyanobenzene (DCB) with **(76)** as a photoredox catalyst afforded α-arylamines in good yields (Schemes 8.1−8.3 in Fig. 8.13A). Substrates like five-membered pyrrolidine, six-membered piperidine, morpholine, *N*-BOC-piperazine and seven-membered azepane rings with DCB resulted in a high yield (91%−98%) of C−H arylated products. The variation of the R substituents with methyl, halogen and naphthyl groups in *N*-R substituted amines showed a high yield of 81%−93% (Scheme 8.1 in Fig. 8.13A). The non-aryl protecting group, e.g., dimethoxybutane (DMB) also showed a high yield of the C−H arylated product in 78% with > 20:1 regiomeric ratio (r:r) (product b in Scheme 8.1 in Fig. 8.13A). The medicinally important cyclic amine structures, e.g., protected indoline was also subjected for C−H arylation reaction, which showed a distinct preference for the arylation at the ring position as opposed to the acyclic benzylic site (product C in Scheme 8.1 in Fig. 8.13A). The scope of the variation of substituents in the aryl rings in the α-aminearylation was also studied. Benzonitriles substituted with esters, amides, phosphonate esters, electron-deficient tetrazoles and heterocycles were found to be suitable substrates for the C−H arylation reaction (Scheme 8.2A−C in Fig. 8.13A). In addition, a chloride ion in a five-membered heteroaromatic moiety can function equivalently to CN^- as a leaving group (product d in Scheme 8.2 in Fig. 8.13A). This empowered the arylation of amines with chloro-substituted caffeine, benzoxazole and *N*-BOC benzimidazole. Pharmaceutical agents, such as linezolid (antibiotic) went direct heteroarylation with 2-chlorobenzoxazole in a yield of 58% (Scheme 8.3 in Fig. 8.13A). This result established the scope of drug molecules to participate in the C−H functionalization reaction. For the mechanism, upon excitation, the powerful reductant Ir(III)* [$E_{1/2ox} = -1.73$ V *vs* SCE] reduced the 1,4-DCB [$E_{1/2red} = -1.61$ V *vs* SCE] to produce a dicyanoarene radical anion. The resulting strong oxidant $Ir^{IV}(ppy)_3$ [$E_{1/2red} = +0.77$ V *vs* SCE] underwent SET with the amine generating an amine-radical cation and $Ir^{III}(ppy)_3$ (Fig. 8.13B). The C−H bonds adjacent to the nitrogen atom in the amine-radical cation were found to be weakened by 40 kcal mol^{-1} and underwent deprotonation by NaOAc to give an α-amino radical. Then, a radical-radical coupling reaction between the dicyanoarene radical anion and the α-amino radical followed by the elimination of CN^- afforded the aromatized benzylic amine product.

8.4.3 Application of Ir(III) complexes in biological sensing of metal-ion

Ir(III) complexes have also been used for biological sensing of the photophysically inactive Zn(II), as ZIrdfppy, **(101)**, ZIrdCF_3, **(102)** and ZIrfppy, **(103)**, (where dfppy = 2-(2,4-Diflourophenyl)pyridine, dCF_3 = 2,4-Bis(trifluoromethyl)phenyl]pyridine, fppy = 2-(4-fluorophenyl)pyridine) (Fig. 8.14A) (You et al., 2014). The complexes **(101−103)** showed ^{3}MLCT emission as the parent complexes without the chelated Zn(II) ion at 499−548 nm; however, the Φ_{PL} values of **(101−103)** were in the range of 0.14−3.0% in degassed MeCN at RT. The complexes were judiciously designed with a Zn(II) receptor, di-2-picolylamine (DPA) at the *para* position of the phen ligand through a methylene linker to sense the Zn(II) ions. In this dyad structure, the photoexcitation of the ^{3}MLCT transition promoted the photoinduced electron transfer (PeT) from DPA to the photoexcited iridium species, effectively suppressing the ^{3}MLCT emission of the Ir(III) complex and lowering the Φ_{PL} values of **(101−103)** compared to those of the parent analogous complexes without the pendant $-CH_2-$ bridged DPA group (Φ_{PL} = 11−23%). The binding of Zn(II) to the DPA reduced the electron-donating ability of the later to the Ir(III) complex, which resulted in the restoration of the phosphorescent ^{3}MLCT emission of the Ir(III) species, i.e., phosphorescence was turned on. To confirm the PeT from DPA, an experiment was conducted, in which tri-2-picolylamine (TPA) was used instead of DPA as the electron donor. TPA affected the phosphorescence decay of the Irdfppy, Irfppy and IrdCF_3 parent complexes of Ir(III) and the bimolecular rate constants for PeT (k_{PeT}) from TPA to the Ir(III) complexes were found to be in the range of (6.0−7.5) × 10^6 $M^{-1}s^{-1}$. The phosphorescence turn-on ratios were quantified by the dynamic range [DR = Φ_{PL} (Zn^{2+})/Φ_{PL} (Zn^{2+}-free)] values as 31 (for **102**), 12 (for **102**) and 2.9 (for **103**). An additional mechanism for the phosphorescence turn-on response of zinc-ion probes was proposed from the femtosecond laser flash photolysis study. The Ir(III) analog of complex **(101)** without the pendant $-CH_2-$ bridged DPA group showed transient absorption bands at 540 and 1100 nm due to the phen radical anion ($phen^{\bullet -}$), signifying the generation of the ^{3}MLCT transition state involving the phen ligand ($ML_{N^{\wedge}N}CT$), which hypsochromically shifted to 530 and 1000 nm for ZIrdfppy (Fig. 8.14B). This showed a different origin for the charge-transfer state as DPA can be more easily oxidized than the Ir(III) center (1.28 *vs* 1.56 V *vs* SCE) and this transient absorption of $phen^{\bullet -}$ of zinc-free ZIrdfppy was attributed to charge transfer from DPA. Thus, an $IL_{N^{\wedge}N}CT$; i.e., DPA → phen charge transfer took place (Fig. 8.14C), resulting in weak phosphoresce in ZIrdfppy as also observed in the lowering in Φ_{PL} values. Complexes

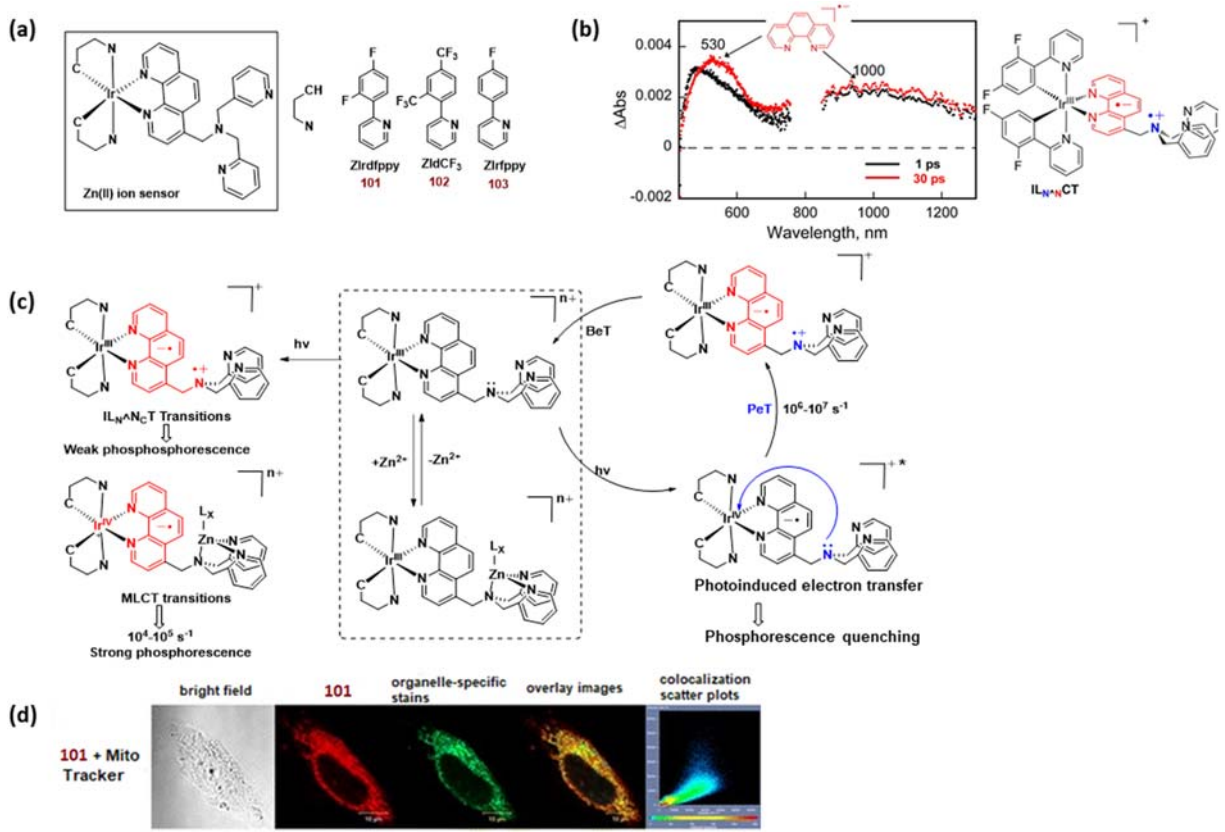

FIG. 8.14 (A) Structure of phosphorescent sensors of Zn(II), (B) femtotransient absorption spectra of zinc-freeform of 0.30 mM **(101)** measured at 1 ps (black curves) and 30 ps (red (gray in print version) curves) delay after photoexcitation at 420 nm, (C) proposed photophysical mechanism for phosphorescence signaling and (D) mitochondrial localization of ZIrdfppy in HeLa cells, 10 μM **(101)** (10 min incubation at 37°C; $\lambda_{exc} = 405$ nm; $\lambda_{em} = 406-550$ nm) and 500 nM MitoTracker deep red FM (45 min incubation at 37 °C; $\lambda_{exc} = 633$ nm; $\lambda_{em} = 637-758$ nm). *Adapted from You, Y., Cho, S., Nam, W., 2014. Cyclometalated iridium(III) complexes for phosphorescence sensing of biological metal ions. Inorg. Chem. 53 (4),1804−1815. With Permission.*

(101−103) were found to be cell-permeable once added to the culture media and were found to be confined on the HeLa cells. At 310 K, media containing 5−10 μM of **(101)** eagerly entered live HeLa cells and showed the lower phosphorescence intensity due to DPA → phen $IL_{N^{\wedge}N}$ CT. The colocalization experiments with organelle-specific stains, e.g., MitoTracker Deep Red FM, discovered the localization of **(101)** within the mitochondria of the HeLa cells (Fig. 8.14D). The confocal laser scanning microscopy images of live A549 cells preincubated with 5 μM of **(101)** initially exhibited weak phosphorescence, but the successive addition of the zinc ionophore, $ZnCl_2$/NaPT (PT = 2-pyridinethiol-1-oxide), turned on the phosphorescence. A stronger Zn(II) chelator, *N,N,N′,N′*-tetrakis(2-picolyl)ethylenediamine (TPEN), restored the lower phosphorescence intensity; thus, indicating the re-occurrence of $IL_{N^{\wedge}N}$CT; i.e., free DPA → phen charge transfer. Such monitoring of the cellular flux of Zn(II) suggested effective sensing of zinc-ion-rich specimens, e.g., hippocampus.

8.5 Conclusion

In this chapter, the synthesis, photophysics and photochemistry of complexes of group 9 (Co, Rh, Ir) elements have been presented. The impact of various ligands like polypyridyl, carbene, thiazole, quinoxaline and phenanthrene, tuning the excited-state photophysics of the complexes of this group (Co, Rh, Ir) have been discussed. It was concluded that Co(II/III) complexes mostly show ^{3}LLCT, ^{3}LMCT transitions, Rh(III) exhibit ^{3}MLCT and $^3(\pi\text{-}\pi)^*$ whereas Ir(III) complexes mostly display transitions from the $^3(\pi\text{-}\pi)^*$, ^{3}LLCT and ^{3}MLCT states. It can be seen that in the last few years, numerous works have been done and the development of group 9 complexes in biological sensors, photoredox catalyst, OLED/PhOLED and LEC has come a long way with many more brilliant examples being established. Although abundant work has been achieved on Ir(III)-OLEDs with good EQE values and photoredox catalysis, extensive research is still needed on Co(III)-based photoredox catalysts and Rh(III)-based OLEDs to achieve champion PRCs, useful in organic and medicinal chemistries in particular and to increase the performance and stability of the solid-state lighting device to achieve commercial applications, respectively.

Chapter 9

Coordination compounds of nickel, palladium, and platinum

Athanasios Zarkadoulas and Christiana A. Mitsopoulou
Inorganic Chemistry Laboratory, Department of Chemistry, National and Kapodistrian University of Athens, Athens, Greece

9.1 Introduction

Group 10 compounds of nickel, palladium, and platinum have been used as paradigms over the years of evolution of inorganic chemistry, from early stages of chemical kinetics that employed Pt(II) compounds for the mechanistic studies of square planar complexes and factors that govern these processes (Basolo and Pearson, 1962, 1967). As inorganic chemistry evolved and more properties of metal complexes came into light, it became clear that photophysical process and subsequent photochemical reactions are interwoven with the bonding and electronic properties of metal and ligands, especially for group 10 ions, which differ remarkably. Thus, going down the group from nickel to platinum, several marked differences occur, which have an effect on photophysical properties. First of all, one can mention geometry preferences; nickel can adopt octahedral, tetrahedral, square planar, square pyramidal, and trigonal bipyramidal conformations. On the other hand palladium and platinum, are mostly found under square planar or octahedral geometries. From a traditional point of view, i.e., ligand field theory, it becomes immediately apparent that as the ligands approach the metal ion, they impose a different field symmetry and thus, cause a rearrangement of metal orbitals in terms of energy. As theoretical chemistry and calculations became more sophisticated, it was found that mixing of metal and ligand orbitals give rise to molecular orbitals that now explain electronic transitions and any molecular changes that might take place as a consequence. This evolution will become evident in the progress of this chapter, where initially ligand field photophysics is reported, from a historical but also pedagogical point of view, laying the basics for group 10 metal complexes. Then it proceeds with important classes of

complexes and very recent examples from the literature, where one can discern trends and strategies toward the preparation of photoactive group 10 complexes.

9.2 Ligand field photophysics and photochemistry

9.2.1 Nickel complexes

Nickel, the first element of group 10 under study, adopts various oxidation states and geometries in transition metal complexes. The most notable is $_{28}$Ni(II): [Ar]3d^8, giving rise to 45 microstates which can be reduced to the following free ion terms: $^1S + {}^1D + {}^1G + {}^3P + {}^3F$. Using group theory, one can apply the method used to derive the splitting of various types of orbitals under a specific environment to obtain the splitting of each free ion term in the desired environment imposed by the ligands. Thus, the S term will split in $^1A_{1g}$ (O_h), $^1A_1$ (T_d), or $^1A_{1g}$ (D_{4h}) states. The terms listed here are of g symmetry, since we only work with metal d-orbitals which are centrosymmetric in a field with an inversion center (Cotton, 1990).

In order to construct an energy diagram, one must take into consideration the two extremes, i.e., splitting due to weak- or strong-field ligands. Starting with the simplest, weak-field approximation, finding the matrix elements of the secular determinant under the action of the ligand field potential operator is required. Since exact calculations are beyond our scope at this point, we can readily use that the S term is not affected and P term does not split; a D term splits to T and E terms, F term splits into two T and A terms, while the G term splits to A, an E, and two T terms (Fig. 9.1), in the same way that the corresponding orbital wavefunctions undergo splitting under O_h and T_d symmetries.

For other geometries, as symmetry becomes lower, e.g., in square planar complexes belonging to group D_{4h}, just one parameter Δ (as we had Δ_o or Δ_t for O_h and T_d, respectively) is not enough to describe the energy differences between states. Group theory operations for a square planar Ni(II) complex belonging to the D_{4h} group split the aforementioned free-ion terms in 19 states, so it comes down to the relative energies between states in each complex to properly put them in energy order. The same is valid for other broken symmetries, for example, when Jahn-Teller distortions are present for other d^n configurations.

Of course, in spectra of Ni(II) compounds, not all possible transitions are experimentally observed, since selection rules make some of the transitions forbidden. In this spirit, Orgel diagrams (Fig. 9.2) are also valuable for calculation of spectral parameters for high-spin compounds under a weak field, taking into consideration the two relevant F and P terms for a tetrahedral or octahedral environment (Orgel, 1955). Notice that the non-crossing and spin conservation rules are observed.

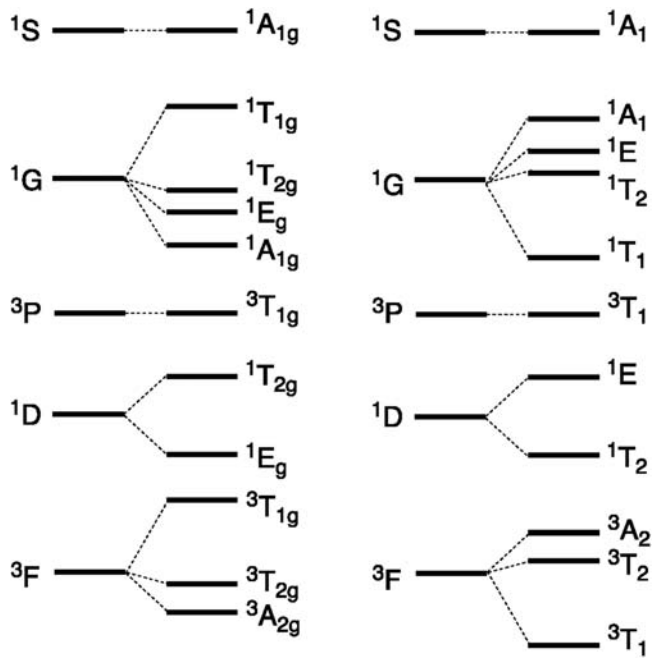

FIGURE. 9.1 Term splitting for Ni(II): $[Ar]3d^8$ in octahedral (O_h, *left*) and tetrahedral (T_d, *right*) environments under the influence of a weak field.

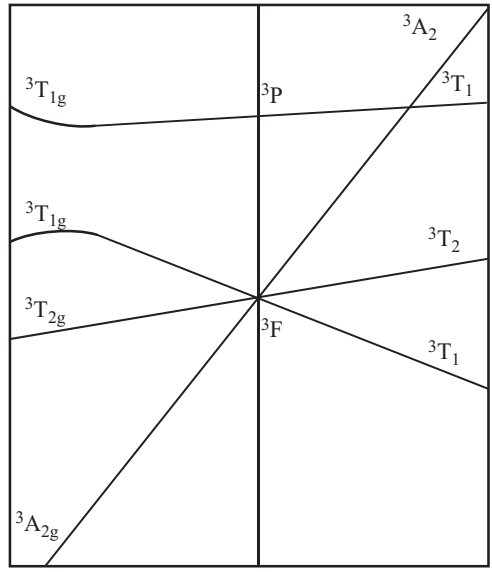

FIGURE. 9.2 Orgel diagram for a Ni(II): $[Ar]3d^8$ ion in O_h (*left*) or T_d (*right*) field.

TABLE 9.1 Band positions and assignments for transitions observed at $[NiL_n]^{2+}$ complexes in aqueous solutions.

L	$^3A_{2g} \rightarrow {}^3T_{2g}$	$^3A_{2g} \rightarrow {}^3T_{1g}$ (F)	$^3A_{2g} \rightarrow {}^3T_{1g}$ (P)
H_2O	8500 (1180)	13,500 (740)	25,300 (395)
NH_3	10,750 (930)	17,500 (571)	28,200 (355)
Ethylenediamine	11,200 (890)	18,350 (545)	29,000 (345)
1,10-Phenanthroline	11,550 (865)	12,700 (788)	-

In this case, calculation of $10D_q$ (Δ_o or Δ_t) and nephelauxetic parameter β can be derived from spectral data and the Racah parameter B for the free ion (Figgis and Hitchman, 1999)

For hexacoordinate complexes of the type $[NiL_6]^{2+}$, band positions are summarized in Table 9.1.

As expected by the spectrochemical series, the increasing π-accepting nature of ligands induces a blue shift in each band and in the case of 1,10-phenanthroline, the high-energy transition is lost in the ligand-based, charge-transfer transitions observed in the UV region of the spectrum. A typical splitting in the middle band may occur for weak field ligands, which is attributed to mixing with ^1E_g (^1D) first singlet excited state.

For a typical Ni(II), $3d^8$ complex, a square planar configuration is preferred due to orbital stabilization, leaving the antibonding $3d(x^2-y^2)$ orbital vacant. As a typical example, the diamagnetic yellow $[Ni(CN)_4]^{2-}$exhibits two bands at ~18,000 and ~23,000 cm^{-1} (Oppenheim et al., 2019). Using single-crystal absorption data, theoretical calculations, and taking into consideration the significant π-back bonding of nickel ion to cyanide, the correct orbital series for the aforementioned square planar complex was found to be:

$$d(xy) < d(xz) < d(yz) < d(z^2) < p(z) < d(x^2-y^2) < p(x), p(y)$$

Thus, the following assignments were made: the transition found at 18,154 cm^{-1} (551 nm) as $^3B_{1g} \leftarrow {}^1A_{1g}$ ($b_{1g} \leftarrow a_{1g}$) and the band at 23,844 cm^{-1}(420 nm) $^3E_g \leftarrow {}^1A_{1g}$ ($e_g \leftarrow b_{1g}$). Other bands at 35,220 cm^{-1} (284 nm) and 37,590 cm^{-1} (266 nm) were assigned as 3d to 4p transitions. However, this orbital order has been disputed in another work (Deeth, 2020). Earlier work regarding irradiation of an aqueous solution of this complex ion at 254, 313, and 365 nm did not report any chemical change after irradiation (Moggi et al., 1966).

9.2.2 Palladium and platinum complexes

Contrary to Ni(II) complexes, the majority of palladium and platinum complexes prefer square planar geometry, based on the stabilization of the occupied d metal orbitals and destabilization of unoccupied $d(x^2-y^2)$ orbital. Ligand field

splitting (Δ) generally increases in the second and third row transition metals and spin-orbit coupling becomes more prominent as the atoms become heavier, with consequences on geometry, kinetic stability, and electronic properties. In fact, d-d transitions in square complexes of palladium and platinum lead to population of antibonding orbitals that eventually lead to distortions in the excited state and subsequent photochemical reactivity. These complexes are typically not luminescent in solution due to non-radiative decay pathways, but may exhibit emission in the solid state or low temperature, where distortions are minimized, or, typically for square planar Pt compounds in the solid state, stacking along the z-axis involving $d(z^2)$ interactions can lead to interesting photophysical properties (Li et al., 2016 and references therein)

It is instructive to examine the series $[MX_4]^{2-}$, where M = Ni, Pd, Pt and X = halogenide. In the case of Ni(II), the field induced by halides is not strong enough to lead to a square planar conformation and typically $[NiX_4]^{2-}$ complexes possess a tetrahedral conformation to achieve the minimum stereochemical and electronic repulsions between ligands. Pd(II) and Pt(II) analogs, on the other hand, are essentially square planar. Complex ion $[PtCl_4]^{2-}$ displays ligand field bands at 330, 400, and 475 nm and an LMCT band at 254 nm (Xian etg al., 2021). Irradiation with LED lamps of different wavelengths leads to stepwise hydrolysis of the platinum complex to yield aquo complexes; irradiation at the LMCT band leads to faster hydrolysis, indicating that the same reactive state is reached regardless of the irradiation wavelength (Fig. 9.3).

Tetrachloropalladate exhibits a same pattern (Drew Tait et al., 1991) i.e., an LMCT absorption at 280 nm and d-d-transition at 474 nm appear, which upon UV irradiation leads to the formation of Pd nanoparticles, following aquation and reduction reactions (Kundu et al., 2010).

9.3 Charge-transfer photochemistry

9.3.1 Diimine and dipyrrin complexes

A plethora of group 10 complexes can form stable, chelate complexes with multidentate ligands, many of which exhibit interesting photophysical properties. Diimine complexes analogous to the very versatile and scrutinized $[Ru(bpy)_3]^{2+}$ chromophore are of interest. In this spirit, the nickel analog, $[Ni(bpy)_3]^{2+}$ will be examined here. Spectroscopic studies of this compound in aqueous solution showed ligand field-based bands in the visible region and two bands in the ultraviolet region (296 and 308 nm) (Sadhiya Banu et al., 2011). Laser flash photolysis revealed transients involving ligand-centered events, leading to generation of ligand-centered radicals. Continuous photolysis led to decomposition of the complex. Since Ni(II) possesses a $t_{2g}^6 e_g^{*2}$ electron configuration, the ligand-centered electronic excitation of the complex involves increased electron density at the antibonding $d(x^2-y^2)$ and $d(z^2)$ orbitals. This induces elongation of Ni−N bonds, which in turn explain the decomposition of the complex (Fig. 9.4).

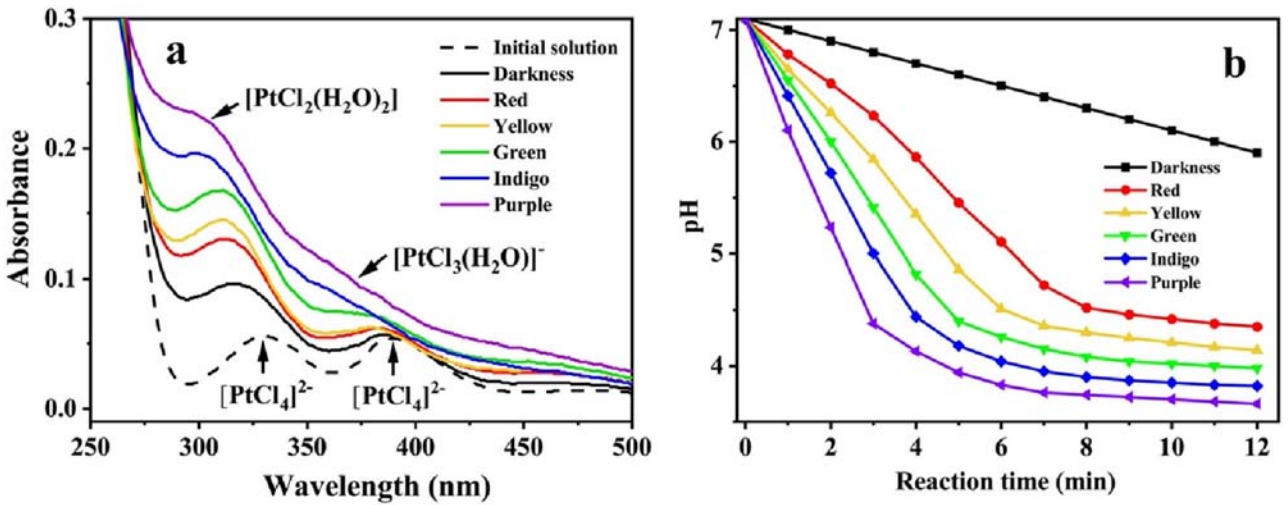

FIGURE. 9.3 Irradiation of an aqueous solution of $[PtCl_4]^{2-}$. *Adapted from Xian, L., Su, B.-Q., Feng, Y.-X., Xi, B., Duan, Z.-Y., 2021. The photochemical effects of visible light on $K_2[PtCl_4]$ hydrolysis and the synthesis of Pt nano catalysts. Inorg. Nano-Met. Chem. 51, 882–888, with permission.*

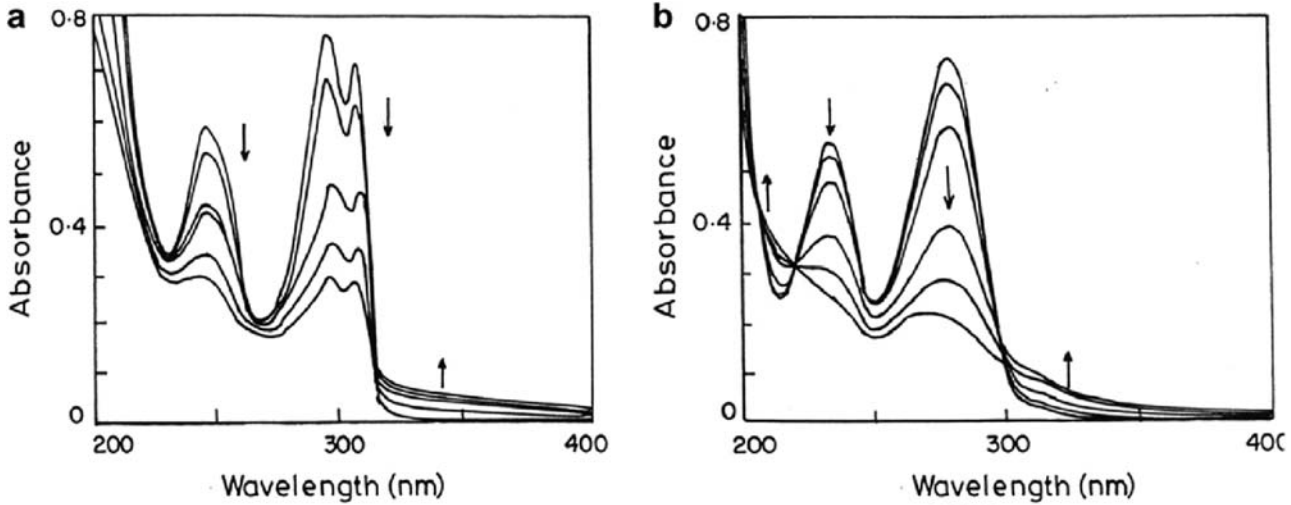

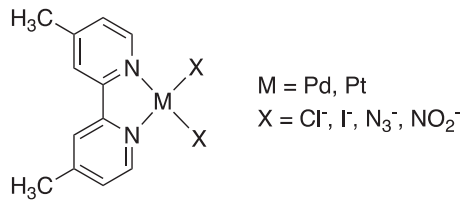

FIGURE. 9.4 Change in the absorbance during irradiation of $[Ni(bpy)_3]^{2+}$ aqueous solution (excitation at 254 nm). *Adapted from Sadhiya Banu, I., Prakash, H., Natarajan, P., 2011. Laser flash photolysis studies of tris(2,2′-bipyridine)nickel(II) ion in aqueous solution. Inorg. Chim. Acta 372, 429–435, with permission.*

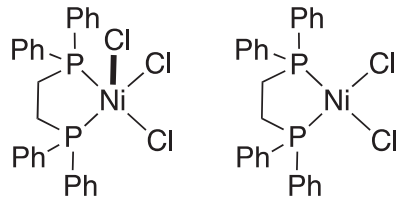

Pd(II) and Pt(II) form mainly neutral complexes of the type $[M(bpy)X_2]$, where M = Pd or Pt and X = monodentate anionic ligand. Complexes containing 4,4′-dimethyl-2,2′-bipyridine (dmbpy) of the type $[Pd(dmbpy)X_2]$ ($X = Cl^-$, I^-, N_3^-, NO_2^-) (Scheme 9.1) exhibit a low-energy MLCT transition around 370 nm and several ILCT bands at the ultraviolet region (Anbalagan, 2003). The assignment for the charge-transfer transition involves an HOMO-LUMO transition between a $d(x^2\text{-}y^2)$-based HOMO to a $\pi^*_{diimine}$-based LUMO. These complexes can successfully sensitize the formation of singlet oxygen ($^1O_2$) in solution. The properties of $[Pt(diimine)X_2]$, Pt-acetylide, and Pt-terdentate complexes have been excellently reviewed by Williams et al. (2007).

Nickel diimine complexes have recently attracted attention due to their utilization in photoredox coupling reactions in sustainable organic transformations. Apart from traditional catalytic protocols that use traceless directing groups of earth abundant 3d metals (Greene et al., 2012; Han et al., 2018; Takahashi et al., 2020; Zarkadoulas et al., 2021), the versatility, user-friendliness, and sustainability of photocatalytic reactions is gaining more and more interest. Chlorine photoelimination from mononuclear, well-defined Ni(III) complexes bearing 1,2-bis(diphenylphosphino)ethane (dppe) and chloride ligands (Scheme 9.2) was achieved with visible light (Hwang et al., 2015) and was attributed to excitation to an LMCT transition at 450 nm (Fig. 9.5). Later, several other complexes have been studied in terms of their photosensitized or direct irradiation photochemistry (Wenger, 2021 and references therein).

Briefly, photochemical dissociation/homolysis of several organometallic square planar complexes occurs after excitation of a ^{3}MLCT state, which then relaxes to metal-centered d-d states, with a concomitant tetrahedral configuration facilitating bond scission/homolysis. This property of Ni complexes in various oxidation states is still under exploration with impressive results in sustainable organic transformations with low cost, first-row transition metals. More detailed studies and scope of catalytic reactions can be found in recent review articles (Tian et al., 2020; Cagan et al., 2020; Kariofillis and Doyle, 2021; Mantry et al., 2021; Till et al., 2021; Campbell et al., 2021; Stevenson et al., 2021; Hu et al., 2021).

Another important, established class of ligands is dipyrrin ligands (Wood and Thompson, 2007; Singh et al., 2020; Baudron et al., 2020). They can accommodate a variety of transition metal ions, support different geometries, and exhibit tunable properties based on steric and electronic factors. Ni(II) dipyrrinato complexes (Scheme 9.3) possess a distorted tetrahedral geometry around Ni(II) ion and exhibit a prevailing absorption band at ∼470 nm in solution. DFT calculations showed that both; HOMO and LUMO are localized on the ligands giving rise to LLCT transitions (Wang et al., 2015; Xue et al., 2017). Although this class of nickel compounds is relatively new and their photophysical study has not been performed in detail yet, heteroleptic Ni-dipyrrinate complexes were found non-emissive at room temperature (Toyoda et al., 2015). Despite their lack of photophysical properties, they have been employed as photosensitizers in photodynamic cancer therapy with negligible toxicity against cancer cells due to poor $^1O_2$ production (Karges et al., 2020) (Fig. 9.6).

SCHEME 9.3 Ni(II) dipyrrin complexes.

With palladium, the situation is slightly different; Pd(II) dipyrrin complexes (Scheme 9.4) adopt a slightly distorted square planar geometry (Mathew et al., 2020), and exhibit weak fluorescence in solution at room temperature, with lifetimes of ∼3 ns at 573 nm. This difference occurs due to the presence of Pd, which, as a heavy atom, facilitates ISC without phosphorescence, based on short lifetimes found (Fig. 9.7).

Imposing a structural rigidity on a Pd(II) phenyl-substituted dipyrrin complex (Scheme 9.5) (Riese et al., 2018) revealed that the flexible or rigid nature of the ligand framework affects its photophysical properties; thus, while

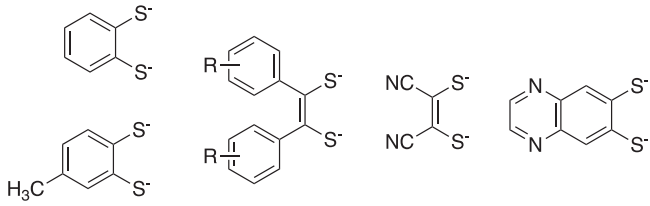
both complexes undergo LC transitions that lead, via ISC, to low-lying triplet states ($\tau = 13$ ps), in the case of the more flexible analog (Scheme 9.4), structural reorganization leads to a non-emissive ^{3}MC state with absence of emission in solution at room temperature (Fig. 9.8).

9.4 Bis-dithiolene and diimine-dithiolene complexes

These complexes comprise a large family of group 10 complexes. The term "dithiolene" or "dithiolate" many times is used interchangeably but actually refers to different resonance forms of the ligand (Scheme 9.6)

The soft base nature of S-donor atoms coordinates with group 10 ions that act as soft Lewis acids to yield a great variety of metal complexes that can stabilize various oxidation states. In fact, the dithiolene ligand framework is classified among other ligands in the large group of "non-innocent ligands",



SCHEME 9.6 Charge localization, resonance forms and nomenclature for a bis-1,2-dithiolene ligand. *Adapted from Zarkadoulas, A., Field, M.J., Papatriantafyllopoulou, C., Fize, J., Artero, V., Mitsopoulou, C.A., 2015. i.e., ligands that render difficult the precise determination of the oxidation state of the metal ion (Eisenberg and Gray, 2011).

Metal bis-dithiolene complexes can be divided in several sub-categories; compounds of the type $[M(bdt)_2]^{n-}$, where bdt = Benzene-1,2-dithiolate and similar aromatic dithiolene ligands, $[M(sdt)_2]^{n-}$, sdt = *Z*-Stilbene-1,2-dithiolate, and bis-heteroleptic dithiolene complexes (Scheme 9.7).

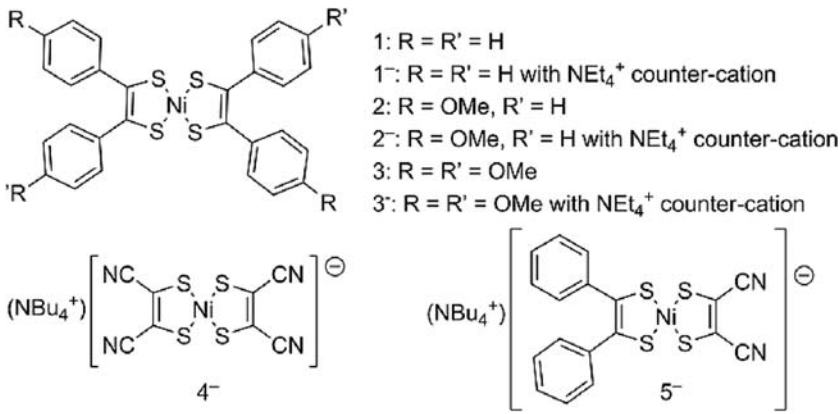
In the first category, each member of series $[M(bdt)_2]^{-}$ (M = Ni, Pd, Pt) is most stable in the monoanionic form but it can be found in the dianionic state as well. They exhibit very intense absorption bands at the nIR region of the spectrum (~900 nm), with molar absorptivity values reaching several thousands. These transitions are of CT character, with different contribution of either metal or ligand HOMO toward a ligand-based LUMO (Cummings and Eisenberg, 2004). Bis-dithiolene d^8 complexes are not usually emissive, although when the heavy Pt is present, longer excited state lifetimes can be observed. Their intense absorption band has been used in sensory applications and dye-sensitization of TiO_2 (Islam et al., 2001; Linfoot et al., 2011; Ghosh and Schulzke, 2016; Jeon et al., 2017).

Heteroleptic [M(diimine)(dithiolate)] complexes (M = Ni, Pd, Pt) exhibit different photooxidation products, depending on the metal (Scheme 9.8) (Zhang et al., 1996; Connick and Gray, 1997). In the dark no reaction was observed for this series of complexes. Using Fukui functions and DFT-TDDFT theoretical calculations, the reactive centers of these complexes can be identified and different sulfur nucleophilicities can be explained (Cocker and

SCHEME 9.7 Various dithiolene ligands.

SCHEME 9.8 Photochemical oxidation products of [M(diimine)(dithiolene)] complexes. *Adapted from Mitsopoulou, C.A., 2010. Identifying of charge-transfer transitions and reactive centers in M(diimine)(dithiolate) complexes by DFT techniques. Coord. Chem. Rev. 254, 1448–1456, with permission.*

Bachman, 2001; Makedonas and Mitsopoulou, 2006; Mitsopoulou, 2010). Since the electronic structure of these complexes involves a mixed-dithiolene-metal HOMO and a diimine LUMO, the different reaction patterns are attributed to the different contribution of each metal in the bonding scheme.



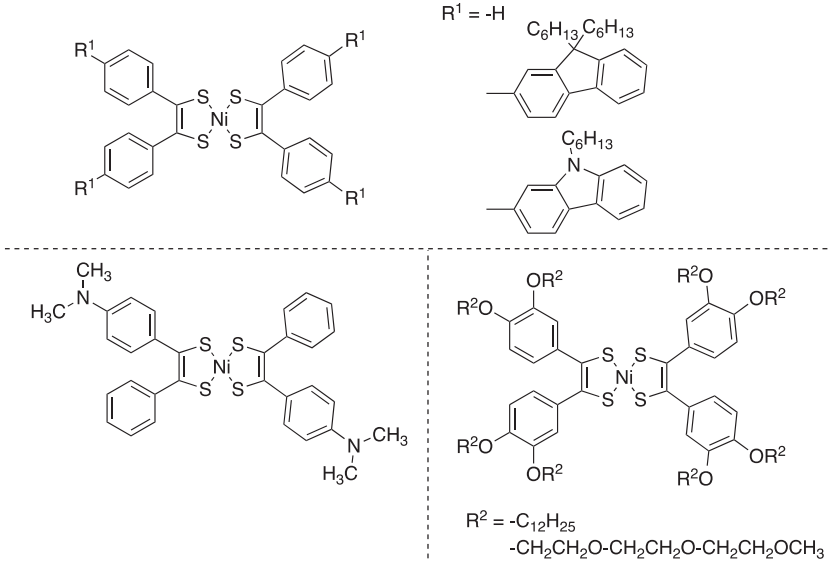
The high nucleophilic nature of sulfur donor atoms has been exploited for both electrocatalytic and photocatalytic hydrogen evolution from acidic media (Zarkadoulas et al., 2012, 2017; Letko et al., 2014). Catalytic activity is not always observed by dithiolene complexes themselves and a photosensitizer may be required. Existing examples of other dithiolene complexes that split water without added photosensitizer may provide insight, combined with the energetics and details of hydrogen evolution mechanism followed by nickel complexes (Humphry-Baker, 1998).

A series of nickel bis-dithiolene complexes has been investigated for the photocatalytic hydrogen evolution reaction from acidic organic media (acetic acid in DMF) in combination with triethanolamine as a sacrificial electron donor, with rhenium(I) diimine of the type [Re(diimine)$(CO)_3$X] complexes as photosensitizers (Koutsouri et al., 2019) (Scheme 9.9).

The different structure of each catalyst has an effect on photocatalytic activity; interestingly, different organic substituents on the organic ligand framework affect the formal charges on sulfur atoms in the NiS_4 core. This has also been shown by similar complexes under electrocatalytic conditions along with DFT studies (Zarkadoulas et al., 2015) that demonstrated how each redox equivalent is stored on the NiS_4 core, indicating how important the second coordination sphere is for this class of catalysts. The proposed catalytic cycle involves the following steps:

The monoanionic catalyst is reduced to the dianionic state, after reductive quenching of the excited photosensitizer. Subsequent protonation at sulfur and further reduction yields a highly reactive, protonated intermediate that can be protonated a second time to yield dihydrogen and the monoanionic catalyst (Drosou et al., 2020). The limiting factor in this case was the dissociating paths followed by the rhenium photosensitizer. The different activity of each catalyst, along with the catalytic superiority of asymmetric and heteroleptic complexes raised questions regarding the possible participation of nickel ion in the catalytic cycle.

Further study of this catalyst class revealed the nature of catalytic cycle upon interfering with the delocalization of electron density on the NiS_4 core (Zarkadoulas et al., 2018; Drosou et al., 2021). Thus, selectively alkylating



SCHEME 9.9 $[Ni(dithiolene)_2]^-$ catalysts for the photocatalytic hydrogen evolution reaction. *Adapted from Koutsouri, E., Zarkadoulas, A., Kefalidi, C., Papatriantafyllopoulou, C., Mitsopoulou, C.A., 2019. Establishing structure–activity relationships in photocatalytic systems by using nickel bis(dithiolene) complexes as proton reduction catalysts. Eur. J. Inorg. Chem. 2019, 4908–4919, with permission.*

two adjacent sulfur atoms by creating a $-CH_2CH_2CH_2-$ alkyl bridge, directs protonation toward the non-alkylated, more nucleophilic sulfur atoms. Electrochemistry and theoretical studies indicated a structural distortion accompanying the reductions in this case, in contrast with the non-alkylated counterparts. Then, subsequent reduction and protonation can take place on the now reduced, Ni(I) ion.

For these catalysts, detailed DFT studies confirm that an increased metal basicity is observed in the case of alkylated nickel bis-dithiolene complexes. Alkylation imposes a specific, more localized, electronic structure on the NiS_4 core, rendering coordinated sulfur atoms capable of acting as internal proton relays that transfer protons to the metal, facilitating protonation of a nickel-hydride species. Similar work for related ligand frameworks has been reported (Das et al., 2015; Drosou et al., 2021; Kamatsos et al., 2021a,b).

Dithiolene complexes also find interesting applications in medicinal chemistry. An initial report can be found on [Pt(pq)(bdt)] (pq = 2-(2′-Pyridyl) quinoxaline, bdt = benzene-1,2-dithiolate) complex (Mitsopoulou et al., 2008) and its interaction with CT-DNA both in the dark and after illumination. More recent studies focus on the use of bis-dithiolene complexes for theranostic applications (Camerel and Fourmigué, 2020). In this context, nickel bis-dithiolene complexes bearing bulky groups (Scheme 9.10) have been prepared (Mebrouk et al., 2015, 2017; Ciancone et al., 2018, 2019; Park et al., 2020; Chen et al., 2021). These organic groups allow incorporation in nanocarriers that, upon nIR irradiation, can be photothermally active and release

encapsulated drugs on specific sites. Compared to other release agents, bis-dithiolene complexes do not produce singlet oxygen upon irradiation, require low power laser intensity, and are effective in low concentrations. Additionally, typically for this class of compounds, nIR absorption can be finely tuned by altering the ligand framework, with absorption maxima spanning 900–1700 nm (Fig. 9.9).

9.5 Salen-type complexes

Salen complexes of the type shown in Scheme 9.11 and related Schiff base complexes have long been studied for their catalytic properties (Cozzi, 2004).

In terms of group 10 salen complexes and their photochemistry, nickel complexes have been reported in early 2000s (de Castro et al., 2002), where several Ni(II) complexes with different peripheral substitutions were reported. They exhibit absorption in the range of 255–415 nm involving LLCT and MLCT transitions, and they are emissive after excitation at the MLCT band at 425 nm, with observed $\lambda_{em.} = 580$ nm and quantum yields reaching 0.08 for fluorescence. Stern-Volmer analysis for O_2 quenching rate constants were found in the order of $>10^9\ M^{-1}\ s^{-1}$ (Fig. 9.10 and Scheme 9.12).

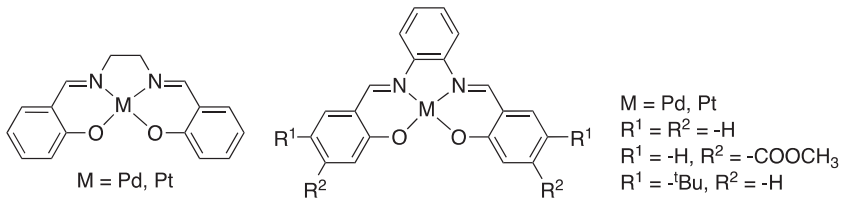
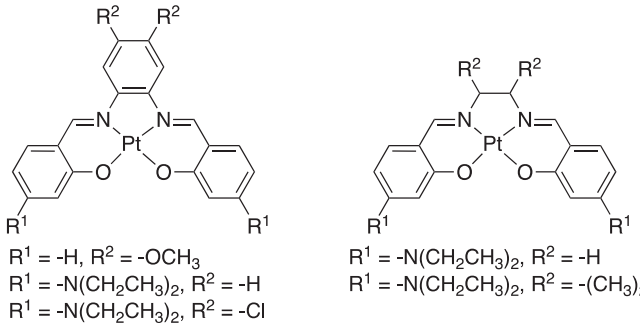
SCHEME 9.12 [Ni(salen)] complexes with various substitution.

Photophysical study revealed an initial metal-to-ligand electron transfer from d_{Ni} orbitals to π^*_{salen} orbitals, yielding an excited state with charge separation. Deactivation from this state accounts for the emission observed, while intersystem crossing to the triplet state results in a short-lived (μs) transient detected by flash photolysis. Substitution on the salen ring did not have an effect on the pathway but affected the excited state lifetimes.



Related complexes [Pd(salen)] and [Pt(salen)] are reported to be non-emissive and slightly emissive ($\phi = 0.19$). Based on theoretical calculations (Tong et al., 2014), for the case of Pd this is attributed to the population of a d-orbital excited state after excitation, and a subsequent fast, non-radiative decay occurring before ISC, preventing any emission (Scheme 9.13).

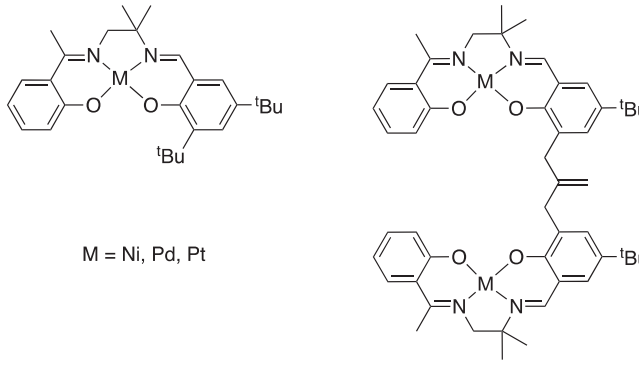
In this type of Pd complexes, σ_{Pd} d-orbitals are positioned higher than π^*_{salen} orbitals. Since σ symmetry d-orbitals of Pd are difficult to influence, peripheral modification of the salphen ligand that leads to lowering of π^* orbitals is a way to prepare emissive Pd(II) salen-type complexes. Indeed, introduction of -COOMe groups led to complexes with weak triplet emissions and short lifetimes ($\tau < 0.2$ μs, $\phi = 1.7 \times 10^{-4}$).



The case with [Pt(salen)] is quite different; although the bonding scheme is similar to the Pd analog, the metal contribution in this case is larger, giving rise to singlet MLCT/IL excited states. Combined with the lower energy of σ_{Pt} d-orbitals, the MC d-excited state is lifted above the singlet excited states. Then, excitation at 390 nm can lead to population of either MLCT or IL singlet excited states with triplet states in proximity that allow efficient ISC and observation of phosphorescence.

The intrinsic photophysical properties of Pt-salen complexes have found applications in the development of luminescent probes for G-quadruplex DNA (Wu et al., 2009), bearing similarities to $[Pt(terpy)]^+$ complexes that have been used for the same purpose (Scheme 9.14).

Several Pt complexes with varying substitution patterns on either the backbone or the periphery of Schiff base ligand were prepared and their photophysical study revealed ILCT bands at ~390 nm and MMLCT and LLCT bands in the visible region (400−500 nm). A slight negative solvatochromic effect indicative of a polar ground state was also reported. Emission lifetimes of several μs were observed around 600 nm.

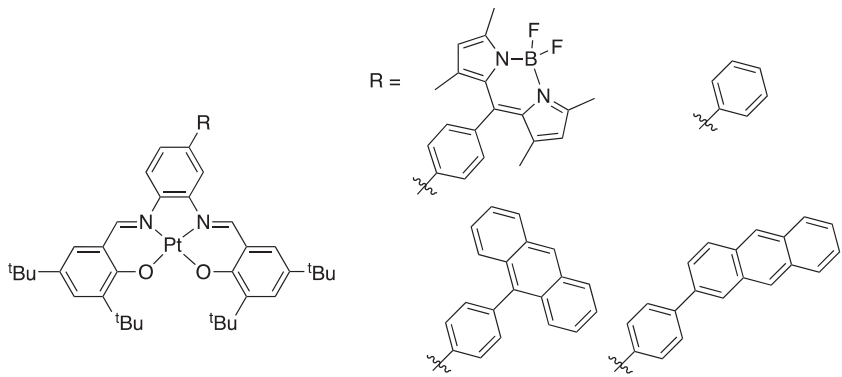


SCHEME 9.13 [M(salen)] and [M(salphen)] complexes.

SCHEME 9.14 [Pt(salphen)] and [Pt(salen)] complexes studied as probes for G-quadruplex DNA.

After initial reports on platinum salen-type complexes, various complexes that have been prepared exhibit interesting optical properties and possible applications in mechanochromic crystalline materials. In one case, a series of bis-salen type group 10 metal complexes has been prepared (Scheme 9.15) (Achira et al., 2016).

The complexes display similar features between the mono- and binuclear counterparts in each case, i.e., ILCT bands in the UV region and wide multiple bands in the region 400−500 nm. In the case of Pt(II), emission and excitation spectra of the mononuclear and binuclear complexes are similar, indicating no significant interaction between the two moieties. Solid state absorption spectra for both Ni(II) and both Pd(II) complexes were similar to thin-films prepared in this study, but in the case of binuclear Pd(II) complex, the spectrum was more finely structured, owing to fixed crystal conformations of the molecules. However, the single-crystal spectra of Pt(II) complexes exhibited different behavior compared to the thin films, with an extra absorption band observed at 520 nm. A similar band observed for the Ni(II) complexes was attributed to d-



SCHEME 9.15 Mononuclear and binuclear salen complexes of group 10 metals.

d transitions. Crystal crushing and smearing experiments revealed different optical properties for the Pt(II) complexes under mechanical stress, more pronounced in the case of the binuclear Pt(II) complex, attributed to the semi-rigidity imposed by the organic linker. In a similar case of a rigid, binuclear Pt-salen type complex, the fused organic linker between ligands of the two Pt-moieties leads to probable mixing of $^3MLCT_{Pt}$ and $^3\pi$-π*states that result in emission 700−800 nm (Houjou et al., 2017).

Due to aforementioned interesting properties of salen and salen-type group 10 complexes, peripheral modification of ligand framework led to the preparation of boron dipyrromethene (BODIPY) and anthracene substituted compounds shown in Scheme 9.16 (Razi et al., 2018; Chen et al., 2020).

Selective excitation of BODIPY moiety (490 nm) led to Förster energy transfer to Pt(II) moiety in a 6.7 ps time interval, followed by a fast ISC and triplet-triplet back-transfer to BODIPY. The triplet state had ∼30 times longer lifetime compared to the Pt compound without BODIPY moiety and was studied in terms of triplet-triplet annihilation (TTA) upconversion with a quantum yield of 10% and a large anti-Stokes shift (Razi et al., 2018) (Fig. 9.11).

On the other hand, the anthryl moiety on a similar platinum backbone induces interesting photophysical properties. The Pt(II) complexes exhibit small Stokes shifts, indicating low energy losses during ISC, rendering them useful triplet photosensitizers. Phosphorescence of the Pt-moiety with quantum yields of ∼11% is quenched in the case of complexes bearing anthracene moiety, giving rise to phosphorescence with $\Phi = 4\%$. Transient absorption spectroscopy indicates both triplet anthracene and ^{3}MLCT states, increasing the excited state lifetime of anthryl-complexes compared to phenyl-complex. These complexes have also been used for TTA upconversion, with quantum yield up to 15% (Fig. 9.12).

9.5.1 Other complexes

Since interest in luminescent, first-row transition metals has risen over the last years (Wegeberg and Wenger, 2021), mostly several nickel complexes with various ligand frameworks will be mentioned here, with some recent examples of palladium and platinum complexes as well.

Three cyclometalated Ni(II) complexes of the type NˆCˆN and NˆCˆNˆO (Scheme 9.17) have been scrutinized in terms of photophysical properties; the compound bearing the carbazoyl group exhibits room temperature luminescence with a triplet excited state at low temperatures (Wong et al., 2020). The complexes exhibit intense absorption bands at $\lambda < 350$ nm, attributed to ILCT transitions, and MLCT or mixed LLCT/MLCT transitions in the region of 350−500 nm (Fig. 9.13).

The carbazoyl-substituted complex exhibits a broad, structureless emission band with a maximum at 600 nm, which shows vibronic structure at 77 K, along with intense emission intensity in solids and glass matrices.

Due to the square planar geometry of the rigid, tetradentate complex of Scheme 9.17, Ni−Ni interactions occur and cause aggregation. This becomes evident in concentration-dependent UV-vis spectra, where a new band rises at 480 nm, which is attributed to formed aggregates.

A nickel(II) complex bearing a non-innocent ligand, incorporating both an oxime and pyridyl moiety (Scheme 9.18) (Pramanik et al., 2017) exhibits broad absorption bands in the 400−650 nm region, attributed to ligand-based, charge transfer transitions. Excitation at either absorption maximum leads to broad luminescence around 410 nm, with quantum yields of ∼6%.

As a substitute to different 3d transition metals complexes that exhibit spin-crossover properties, nickel complexes bearing phenazine ligands display

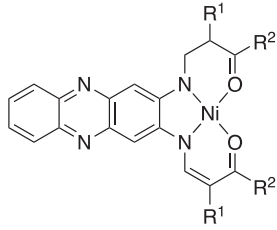
SCHEME 9.18 Ni(II) pyridyl-azooximate complex.

coordination-induced spin state switch (CISSS) (Kurz et al., 2021). The ability of the compounds to undergo conformation changes, which in Ni(II) complexes are accompanied by coordination geometry (square planar diamagnetic to square pyramidal or octahedral paramagnetic), can be monitored by fluorescence spectroscopy.



The complexes exhibit intense absorption bands near 420 nm, with high molar absorptivity values ($\sim$40,000 M^{-1} cm^{-1}) in chloroform. The complex with $-CF_3$ groups is non emissive, contrary to the other compounds which emit at 476 nm, when excited at 385 nm. TD-DFT studies revealed both HOMO and LUMO to be of phenazine nature and charge transfer transitions from the NiN_2O_2 moiety to the phenazine, rendering the transitions MLCT. The opposite is observed for the $-CF_3$ substituted compound, where the transition is inverted and is assigned to be LMCT in nature. Quite long fluorescence lifetimes were observed for the complex $R^1 = -COOCH_2CH_3$, $R^2 = -CH_3$(1 ns) and the emission lifetime extends to 1.8 ns at lower temperatures.

Recording absorption spectra at different pyridine/chloroform ratios drastically change, when pyridine:complex ratio is 30,000:1. At even higher ratios, two bands appear at 370 and 510 nm, which are indicative of the formation of five- and six-coordinate species that resulted from CISSS. Remarkably, the fluorescence quenching by Lewis bases was reported to occur in the singlet state of the excited chromophore (Fig. 9.14).

In the same spirit of preparing planar Ni(II) complexes with intriguing photophysical properties, multifunctional nickel complexes with three functionalities have been prepared (Scheme 9.20) (Alrefai et al., 2021). Although these complexes are not emissive, significant conclusions can be drawn regarding the design of multifunctional Ni(II) chromophores.

In each Ni(II) complex, the aromatic ring system becomes extended, going from phenanthroline to dipyridophenazine and tetrahydrodipyridophenazine, with increasing delocalization, and this has a small effect on the charge transfer absorptions. However, different ligands coordinated on Ni(II) modulate the absorption in the visible region, spanning from 350 to 750 nm.

By design, the π-extended ligands affect the LUMO, and the coordinated co-ligand R-E, along with Ni(II) contribution, is responsible for modulation of the HOMO. The remaining moiety, i.e., the pendant aryl arm, actually modifies the energy of (occupied) donor and (unoccupied) acceptor frontier molecular orbitals. The subtle balance of these three contributing factors leads to the observed situation: when an excited state is populated due to Ni-donor-to-π-system charge transfer transition, nonradiative decay takes place due to

R^1 = -$COOCH_2CH_3$, R^2 = -CH_3
R^1 = -$COOCH_3$, R^2 = -CH_3
R^1 = -$COCH_3$, R^2 = -CH_3
R^1 = -$COOCH_2CH_3$, R^2 = -CF_3

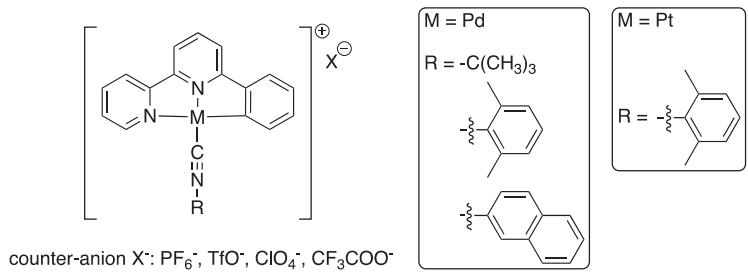
SCHEME 9.20 Structures of multifunctional Ni(II) complexes.



conformational rotations, which adds a Ni(III) character to the excited state. The presence of phenolate oxygen stabilizes the HOMO and contributes more to its orbital character, when compared with the C-coordinated aryl ring.

In the field of Pd(II) complexes, recently progress has been made in emissive isocyanide complexes (Wan et al., 2018).

These complexes display intermolecular interactions that give rise to emissive ^{3}MMLCT excited states in various aggregation states. Bands below 400 nm are attributed to ILCT or mixed IL-MLCT transitions, and interestingly, changes in solvent system induced aggregation with the concomitant emergence of a new band at 439 or 389 nm, depending on the complex. Detailed photophysical study revealed that the pincer complexes display emission based on either singlet or triplet MMLCT excited states at room temperature that is influenced by the formation of aggregates in various extents. In fact, the HOMO-LUMO gap is modulated by the degree of aggregation (Fig. 9.15).

In this context, several macrocyclic complexes of Pd(II) and Pt(II) encompassed by a modified porphyrinoid core, have been reported as fluorescent but not phosphorescent in the nIR region (Scheme 9.22) (Yao et al., 2019).

The absorption spectra of Pd(II) and Pt(II) complexes display intense bands at 300−400 nm and broad bands at 500−600 nm, and upon excitation at 500 nm display intense emission at ∼600 nm in the case of −CN substituted complexes and a weak emission at 550−800 nm for the electron donating groups $-NMe_2$ and −OMe (Fig. 9.16).

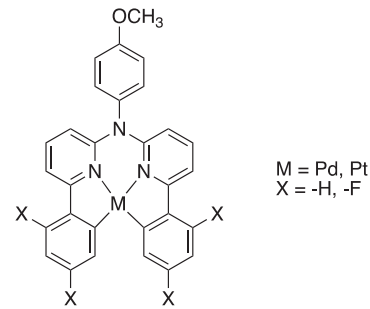
Unusual near infrared (NIR) fluorescent palladium(II) macrocyclic complexes containing M−C bonds with bioimaging capability. Chem. Sci. 10, 10170−10178, with permission.*



Upon complexation of either Pd(II) or Pt(II), a bathochromic shift is observed for absorption and emission spectra of free ligands, pointing to small differences in both; ground and excited states. The Pd(II) complexes exhibit strong nIR fluorescence, but contrary to structurally similar Pd(II) porphyrins, no phosphorescence is observed. Time-dependent spectroscopy and TD-DFT studies of both Pd and Pt complexes with $R^1 = R^2 = -H$ suggest that triplet state is not populated, owing to a small spin-orbit coupling effect that occurs due to large energy gaps and molecular orbitals mainly of ligand character. These photophysical properties can have applications in bio-imaging applications, since the dimethylamino-substituted complex can act as a pH probe in HeLa cells.

As rigid structures have proved beneficial for enhancing emission from group 10 complexes, another report deals with tetradentate Pd(II) and Pt(II) complexes with long-lived excited states (Maisuls et al., 2021) (Scheme 9.23).

The complexes display absorption bands in dichloromethane solution at 235−300 nm (^{1}LC) and exhibit several bands in the region 350−450 nm. The latter are assigned to transitions into ligand centered and low-lying MLCT states (Fig. 9.17).

The Pt(II) complexes exhibit emission at 508 and 544 nm, with a slight shift in the case of fluorinated compound, where emission maxima are found at 489 and 524 nm. The emission profile is similar for the Pd(II) complexes ($\lambda_{em.} = 481$ and 473 nm). At room temperature, non-radiative decay pathways are accessible via metal-centered orbitals for the Pd(II) complexes, making them non-emissive at this temperature, since $\Phi_{lum.} < 2\%$ for Pd(II) compounds even under Ar ($\Phi_{lum.} = 27$ and 36% for Pt(II) complexes with −H and −F ligands, respectively). Based on DFT calculations and spectroscopy at different temperatures, it was concluded that the emission spectra of Pd(II) complexes can be attributed to dimers with ligand-centered and excimer character. Also, the Pt(II) complexes possess a more pronounced MLCT character than the Pd(II) analogs, but the structural confinement favors all complexes in terms of avoiding non-radiative deactivation pathways. The

Ligand-controlled and nanoconfinement-boosted luminescence employing Pt(II) and Pd(II) complexes: from color-tunable aggregation-enhanced dual emitters towards self-referenced oxygen reporters. Chem. Sci. 12, 3270−3281, with permission.*

monomeric fluorinated Pt(II) complex can act as a triplet oxygen sensor, since both its luminescence lifetime and intensity are affected by the presence of $^3O_2$ in its dual emission profile, i.e., monomer emission at 490 nm and insensitive ^{3}MMLCT luminescence found at 635 nm.

9.6 Conclusion

This chapter has sought to present and highlight recent advances in photophysics and photochemistry of group 10 metal complexes, with a focus on nickel complexes, in the spirit of employing earth abundant, low cost, metal ions for fulfilling interesting (photo)chemical reactions. The main factors governing emission from group 10 metal complexes are now apparent and are even more under scrutiny for the case of nickel, where much progress has been made very recently. One of the factors that affect photophysical and photochemical properties is geometry in terms of rigidity and flexibility, and fine tuning of steric factors combined with careful choice of electronic properties modulators via ligand design. As structure—properties become more clarified, one can prepare multifunctional complexes with applications in sustainable catalysis for chemical transformations, solar fuels utilization and hydrogen evolution, materials chemistry, and medicinal or theranostic applications.

Chapter 10

Coordination complexes of copper, silver and gold

Gustavo A. Álvarez and Esteban Mejía
Leibniz Institute for Catalysis (LIKAT), Rostock, Germany

10.1 Introduction

Copper, silver and gold, the three non-radioactive members of the 11th group in the periodic table, have played a protagonist role in the history of mankind. This is not only because its importance in the early days of metallurgy (as they were most certainly the first metals known to man), but also as the embodiment of power and the basis of money. Hence, these have been traditionally known as "Coinage metals".

The photosensitivity of certain metal salts is a phenomenon known since the early days of chemistry. Perhaps the first rigorous scientific investigations on the "Combustible principle in light" were carried out by the Pomeranian chemist Carl Wilhelm Scheele around 1768-1770 (Lennartson, 2017) In his famous treatise *ChemischeAbhandlung von der Luft und dem Feuer,* Scheele (1777) described the detection and isolation of (metallic) silver black from silver carbonate and silver chloride samples previously exposed to sunlight. Moreover, Scheele also observed that when light was divided into its different colors by a prism and shown over a piece of paper treated with silver chloride, it was the violet portion of the spectrum, which had the most destructive effect on the silver salt. This observation, unbeknownst to Scheele, was the first photochemical experiment and the laying ground of the field of photography (Eaton, 1965; Belloni, 1997). By the beginning of the 21st century, the photographic film industry was responsible for about one-third of the world's silver consumption (Mak et al., 2005).

Away from their applications in photography, during the last decades, the most exciting developments in the field of photoactive metal compounds have been driven by their success in several "green" and sustainable applications including: solar energy conversion devices, i.e., photovoltaics and dye-sensitized solar cells (DSSSCs) (Cahen et al., 2001; Gratzel, 2003; Yum et al., 2008; Gratzel, 2009; Kalyanasundaram and Gratzel, 2009; Bella et al., 2015), light sources like organic light-emitting diodes (OLEDS) (Bergmann

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00002-2

et al., 2016; Yersin et al., 2017; Lian et al., 2019; Hong et al., 2021), and, importantly, as photocatalysts and photosensitizers in a myriad of chemical reactions (Zeitler, 2009; Narayanam, 2011; Xuan and Xiao, 2012; Prier et al., 2013; Yoon et al., 2010; Schultz and Yoon, 2014; Marzo et al., 2018; Chen et al., 2016; Bryden and Zysman-Colman, 2021). This is especially true for metal complexes of d^{10} metals, i.e., monovalent copper, silver and gold, which display a rich photoredox chemistry, producing highly reducing (and oxidizing) excited states upon visible light absorption. The high reactivity of these species has been exploited in various fields of applied sciences. These include photocatalysis for organic synthesis and energy conversion technologies (Reiser, 2016; Paria and Reiser, 2014; Witzel et al., 2021; Hopkinson and Dix, 2019; Sandoval-Pauker et al., 2021; Hossain and Bhattacharyya, 2019; Nicholls and Bissember, 2019; Huang et al., 2002), in which copper complexes play an increasingly important role, and in medicine (Langdon-Jones and Pope, 2014; Yam et al., 1994; García Calavia, 2018; Sherwani et al., 2015), where particularly gold nanoparticles and composites have been actively used in the development of photodynamic therapeutic agents and antitumor drugs.

The historical developments that lead the field to its current status and provided the theoretical basis for its understanding will be left out of this account, as there are uncountable excellent text books, chapter and reviews available covering this matter (Yersin and Vogler, 1987; Bitterwolf, 2006; Balzani et al., 2007; Maldotti, 2009; Daniel, 2011, 2015). In here, without aiming to be encyclopaedical, we will discuss the most representative examples from in the last decade (2010−20) an overview of the scientific trends and societal necessities have been provided that have inspired these endeavors.

To simplify the structure of this chapter and to avoid unnecessary repetition, explanations of the photophysical principles and theories that govern the photochemistry of complexes of the 11th periodic group have been only given in detail for copper complexes, as these are by far the most abundant, more thoroughly investigated and those with the widest application palette. Despite the myriad of reported Ag(I) complexes, their photophysical and photochemical studies are relatively scare, compared to the over abundant data available for their Cu(I) congeners. This is chiefly due to the inherent thermal instability and light sensitivity of many silver compounds, thus hampering their preparation and manipulation under ambient conditions. Thus, due to the comparatively scarcity of data, silver complexes have been left out of this overview. A similar picture appears for gold complexes, whose photophysical studies are chiefly focused on multimetalic species and clusters. In this review, focus is on monometallic molecular complexes, since the photophysics and photochemistry of polynuclear and multimetallic species, as well as clusters, has been reviewed extensively elsewhere (Wing-Wah Yam and Kam-Wing Lo, 1999; Tong et al., 2009; Yam et al., 2015; Ravotto and Ceroni, 2017; Lei et al., 2017; Seifert et al., 2020; Zheng et al., 2020). Photoactive polymers, extended self-assembled materials, and plasmon-active

surfaces, from which gold materials have a significant share, are also left out of the scope of this chapter.

10.2 General considerations

Among those coordination compounds, whose photophysical and photochemical properties have been most thoroughly studied, those made from noble metals like ruthenium and iridium occupy the most prominent places. In most cases, such complexes work very well on the intended applications, displaying high photophysical and photochemical performance as well as good stability. However, due to the scarcity and the subsequent high prices of those metals, their widespread use is limited. To bypass such issues, it was proposed that using more abundant, first transition row metals with the adequate set of ligands, the orbital energies and thus, the redox properties of these complexes could be tailored to resemble, or even surpass, the performance of their noble congeners. From these endeavors, it became quickly apparent that from the studied 3d metals, copper was the best suited for the task, thanks to its d^{10} character, facile monoelectronic redox chemistry and stability of its complexes in different available oxidation states (mainly +1 and +2). Thus, to review the development and the last advances in the photophysics and photochemistry of copper coordination compounds, it is necessary to point out the most important properties of these compounds.

Arguably, the most important property is the nature of the metal center, i.e., its (formal) oxidation state. As briefly mentioned above, copper complexes can be found in various oxidation states, namely 0, +1, +2 and, although still debated, +3 (DiMucci et al., 2019). At the lower end of the scale, copper complexes in the zero-oxidation state are thermodynamically stable species that tend to aggregate into clusters and larger macro-structures. At the opposite end of the scale, compounds with +3 oxidation state provide an example of very unstable species (kinetically and thermodynamically), given that extracting a third electron from copper implies leaving the 3d subshell with two orbitals half occupied in a high spin configuration and, as a consequence, Cu(III) species only appear in "exotic" compounds or as postulated reactive intermediates in chemical reactions that cannot be isolated. Thus, their presence is in most of the cases only hypothesized and barely demonstrated. For this very reasons, the photochemistry of Cu(0) and Cu(III) is by no means representative for this metal, and thus, has been left out of this compilation.

On the contrary, Cu(I) and Cu(II) tend to form well defined and more stable coordination compounds in both; solid state and solution. In this regard, Cu(I) coordination compounds are the most studied for photochemical and photophysical behavior both. The reason is that Cu(I) possesses a full 3 d^{10} sub-shell and does not perform metal centered (MC) electronic transitions, being thus the most common transitions metal-to-ligand charge transfer (MLCT) in nature. The photophysical properties of Cu(II) coordination compounds have

been less studied than for Cu(I) complexes, since the former can perform, among other, MC transitions, being prone to easy deactivation of its short-lived excited states through non-radiative process. Nevertheless, several examples of photochemical process including Cu(II) complexes have been reported (Conry, 2005; Lipshutz and Pfeiffer, 2005).

The next parameter to consider is type of ligands at the copper coordination sphere as well as their coordination geometry around the metal center. In the first place, it is known that in the absorption process, the electronic transition HOMO-LUMO needs to fulfill some symmetry parameters to be optimal. Then, the geometry of the complex is of paramount importance and knowing the possible alternatives is advantageous. Hence, as will be discussed in the following subsections, from the historical point of view, the research on photoactive copper complexes can be divided in four periods. First, it was noticed that some copper compounds in both the oxidation states +1 and +2 could carry out some chemical reactions driven by light. However, as the reaction intermediates had only short lifetimes, their structural characterization remained elusive in most of the cases. The second stadium is marked by the discovery of the emissive properties of homoleptic phenanthroline complexes $[Cu(N\hat{}N)_2]^+$, yielding high photoluminescence and quantum yields as well as significantly longer lifetimes. The third epoch comprises was the rise of heteroleptic phenanthroline-diphosphino complexes $[Cu(N\hat{}N)\ (P\hat{}P)]^+$, which overcome some geometry relaxations in the excited state and further extension in the lifetime of luminescent species was reached. The fourth period has been developing during the last decade and it has been marked by the introduction of carbene type ligands, leading to linear or planar complexes or polydentate ligands, pincer-type, and anthocyanin, leading to planar geometries. Furthermore, in the last few years, the combination of both; transient spectroscopy technics and computational chemistry (mainly DFT and TDDFT methods) has gained importance in the characterization of both, ground- and excited-state structure dynamics, supporting the experimental results and allowing to perform a more proper assessment of the different photophysical events, leading to a deeper understanding of these phenomena.

The following subsections are dealing with the photophysical and photochemical properties of different complexes as a function of the oxidation state of the metal, starting with a discussion about Cu(I), which has been the most studied oxidation state, focusing in its homoleptic and heteroleptic complexes, concluding the section with some examples of another type of complexes (miscellaneous).

In the 1970s decade, the photochemistry of Cu(I) systems was subject of increasing interest, especially of those complexes exhibiting photoredox activity. Notably, the group of McMillin (1977), along with their research on blue Cu proteins, discovered a light-induced redox reaction of the homoleptic complex (2,9-dimethyl-1,10-phenanthroline)copper(I),$[Cu(dmp)_2]^+$. Following these pioneering works, this group started the systematic

characterization of the electronic transitions and the emissive character of homoleptic and heteroleptic Cu(I) complexes (Buckner and McMillin, 1978). However, as will be seen in the next section, the research in heteroleptic diamine-diphosphine remained comparatively neglected until early 2000s, when parallel developments in the chemistry of organophosphorus compounds allowed the preparation of new bidentate ligands with high steric demand and large bite-angles thus; giving access to novel diphosphine ligand scaffolds.

As previously mentioned, the efficient non-radiative deactivation of the MLCT states via low lying MC states observed in most transition metal complexes is preclude their application in photochemical processes (Ravotto and Ceroni, 2017; Liu et al., 2018; Förster and Heinze, 2020). However, this problem is circumvented by Cu(I) complexes, where the metal center possesses a 3 d^{10} closed-shell configuration in the ^{1}GS, then the non-radiative deactivation via MC states is absent (Mara et al., 2015; Liu et al., 2018; Förster and Heinze, 2020). In this case, the symmetrical electronic charge distribution in a d^{10} configuration favors a (pseudo)tetrahedral geometry in the GS, and the degree of distortion from the ideal tetrahedral geometry depends on both; the electronic and steric properties of the ligands attached to the metallic center (Armaroli et al., 2007; Lu et al., 2018).

A graphical representation of the most relevant electronic and energetic transitions suffered by a Cu(I) complex upon photon absorption is given in the Jablonski diagram in Fig. 10.1. First, a Frank-Condon (FC) ^{1}MLCT

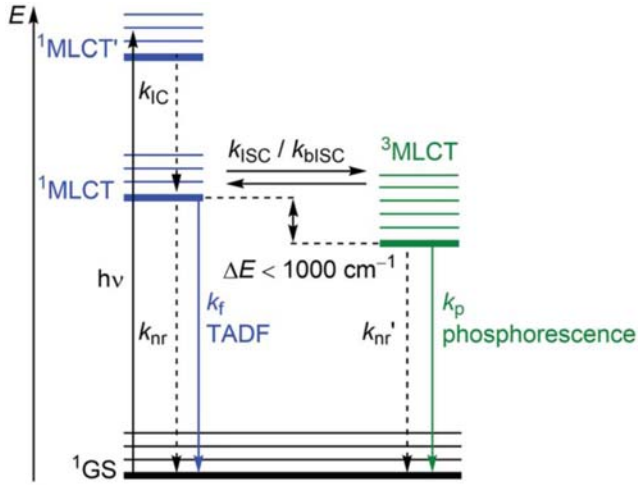

FIG. 10.1 Jablonski diagram illustrating the different photophysical process occurring in a homoleptic Cu(I) complex upon absorption of a photon. *Adapted from Förster, C., Heinze, K., 2020. Photophysics and photochemistry with Earth-abundant metals — fundamentals and concepts. Chem. Soc. Rev. 49, 1057–1070. With Permission.*

vibrationally excited state is formed through a spin and symmetry allowed absorption. In this process, the Cu(I) atom is formally oxidized, yielding a formal Cu(II) excited species, along with a radical anion delocalized in one of the ligands. In the new excited species, the metal center possesses a d^9 electronic configuration and the promotion of the electron from the 3d orbital of the metal to the π^* orbital of the ligand induces a change in the dipolar moment of the molecule driven by the more unsymmetrically distributed electronic density, generating a second order Jahn-Teller distortion, in a process referred as flattening distortion (Liu et al., 2018). As consequence, the minimal energy geometry of the excited state is not (pseudo)tetrahedral but (distorted) square planar, as it is well known for closed-shell Cu(II) complexes.

After its formation, the Cu(II) excited species tends to undergo vibrational relaxation, followed by an internal crossing (IC) to get a more flattened ^{1}MLCT structure. Depending on the energy gap between the latter and the GS, the ^{1}MLCT has two deactivation pathways, either non-radiative, or radiative (luminescent). The former is favored by small energy gaps, due to large vibrational overlaps and by dissimilar geometries of the ^{1}MLCT and the ^{1}GS states, i.e., highly distorted excited state, due to the vibronic coupling (strong coupling limit) (Förster and Heinze, 2020). In the case of luminescent deactivation, an allowed transition from ^{1}MLCT to ^{1}GS produces a photon emission (fluorescence). However, molecules with optimal spin-orbit coupling (SOC) carry out an efficient and spin forbidden inter-system crossing (ISC) to produce a lower energy-lying and long-lived ^{3}MLCT with a subsequent radiative relaxation to the ^{1}GS (phosphorescence), which in general, in absence of coordinating solvents or ligands, is faster than non-radiative deactivations pathways at low temperatures. On the other hand, when the energy difference between the ^{1}MLCT and the ^{3}MLCT states is small and enough thermal energy is available, the long-lived ^{3}MLCT state can enable back-ISC (bISC), leading to a Boltzmann distribution for the emissive $^{1/3}$MLCT state population. As fluorescence is a spin-allowed process, a thermally activated delayed fluorescence (TADF) is more efficient than phosphorescence at high temperatures (Lu et al., 2018; Förster and Heinze, 2020).

All the afore-mentioned process are unimolecular in nature, since many of them (especially the fastest ones including flattening distortion and ISC) are not directly affected by the dynamics of their surroundings (Mara et al., 2015; Iwamura et al., 2015). Moreover, it must be pointed out that some photophysical and photochemical properties, as well as the deactivation pathways are highly influenced by the chemical nature and physical state of the media where, the excited species are generated. The photoluminescent properties of Cu(I) complexes have been studied in different environments and media, including microcrystalline solids, solutions in different coordinating (acetonitrile, THF, methanol, etc.) or non-coordinating solvents (DCM, toluene, chloroform, etc.), both in liquid or solid phase (i.e., at 77 K), as well as in polymeric films. This information has been collected in different reviews

(Lu et al., 2018; Zhang et al., 2018; Forero Cortés, 2021; Sandoval-Pauker et al., 2021) and book chapters (Elie et al., 2017; Mani and Subramaniyan, 2019). Comparison of properties like quantum yields or lifetime of excited species suggests that the luminescent performance increases along with the aggregation state. This phenomenon is known as aggregation induced phosphorescence (AIP), referring to a compound that is non-emissive as an isolated entity in solution but emissive in the aggregated form, or aggregation induced phosphorescence enhancement (AIPE), for a compound that is weakly emissive as moiety and more emissive as an aggregate. In the case of mononuclear Cu(I) complexes, aggregation causes a rigidification both; in the ground- and in the excited states. Then, trapped chromophores in a crystalline or amorphous structure leads to a reduction of molecular motions with respect to the individual molecules in solution. The structural rigidity limits vibration or rotation of appended subunits and hinders structural distortion of the equilibrium geometry of the phosphorescent excited states. Both of these factors lead to a decrease of the rate of non-radiative processes, which deactivate the phosphorescent excited state, resulting in an increase of phosphorescence quantum yield (Ravotto and Ceroni, 2017). However, in solution, without considerable steric constrains, upon light absorption, flattening distortions of the excited complex take place due to the preferred square planar geometry of the *Cu(II) in the ^{3}MLCT state. Thus, the flattened complex enables an extra coordination site at the metal center, where a bimolecular quenching process with a Lewis base (or ligand) could take place. This process is called exciplex formation. Here, the long lived ^{3}MLCT intermediate can accept an additional axial ligand acquiring a square pyramidal geometry (exciplex). Then, as the formed species lowers the energy of the triplet state, the luminescent pathway is inhibited and the exciplex relaxes to the ^{1}GS preferentially through non-radiative processes (energy gap law) (Ravotto and Ceroni, 2017; Förster and Heinze, 2020).

10.3 Homoleptic Cu(I) coordination compounds

Since McMillin et al. (1977) reported for the first time the remarkable photophysical properties of homoleptic Cu(I) coordination compounds, these systems have been widely studied, both practically and theoretically. An overview of the myriad of reports on this section has been not been provided here, mainly because it has been extensively reviewed elsewhere (Armaroli et al., 2007; Lavie-Cambot, 2008; Mara et al., 2015; Sandoval-Pauker, 2021). However, an up-to-date discussion, taking in account the new trends and findings in the area is lacking in the literature. For instance, in the recent years, stepping away from phenanthrolines, new different kind of ligands have been found to exhibit photoluminescent properties. Importantly, hundreds of new homoleptic coordination compounds have been described based on diimines ($[Cu(N\hat{}N)_2]^{+}$), as well as new 1,10-phenantrolines, 2,2-bipyridines,

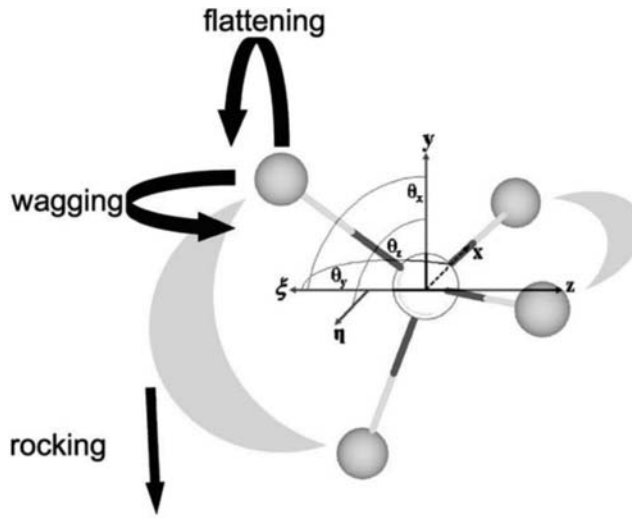

FIG. 10.2 Representation of the ξ_{CD} parameter used to describe the deviation from the ideal tetrahedral geometry in $[Cu(N\hat{}N)_2]^+$ complexes. *Adapted from Armaroli, N., Accorsi, G., Cardinali, F., Listorti, A., 2007. Photochemistry and photophysics of coordination compounds: copper, in: Balzani, V., Campagna, S. (Eds.) Photochemistry and Photophysics of Coordination Compounds I, Springer Berlin Heidelberg, Berlin, Heidelberg, 69–115. With permission.*

bisindazol, or biphosphines ($[Cu(PP)_2]^+$), and more recently, ligands of the type $[Cu(NP)_2]^+$ like phosphinooxazoline or phosphaalkene.

Before providing specific examples, highlight the most important photophysical features of these compounds are highlighted, since their study has paved the way to optimization of photoluminescent performance of other systems by systematic modifications in the ligand architecture throughout chemical synthesis and subsequent structure-activity evaluation.

The ground state geometry of homoleptic Cu(I) complexes with phenanthroline ligands can be described by its ξ_{CD} parameter (Fig. 10.2). This parameter quantifies the distortion from the ideal tetrahedral geometry, and it has been shown (by X-ray crystallography) to be dependent on the substituting groups at the positions two and nine of the phenanthroline scaffold (Armaroli et al., 2007; Lavie-Cambot, 2008).

Regardless of the substituents, the nature of the electronic transitions remains the same when systematic variations in the ligands are performed (Mara et al., 2015). Therefore, the ultraviolet (UV) absorption spectra of these complexes are dominated by LC transitions of the phenanthroline moieties ($50\,000 < \varepsilon < 60\,000\,M^{-1}$). Another common feature are the bands lying in the visible (VIS) region, which are much weaker than those in the UV ($\varepsilon < 10\,000\,M^{-1}$), being assigned to MLCT electronic transitions (Fig. 10.3). Those bands are the sum of three different electronic transitions labeled as band I, II, and II (Armaroli etr al., 2007; Lu et al., 2018).

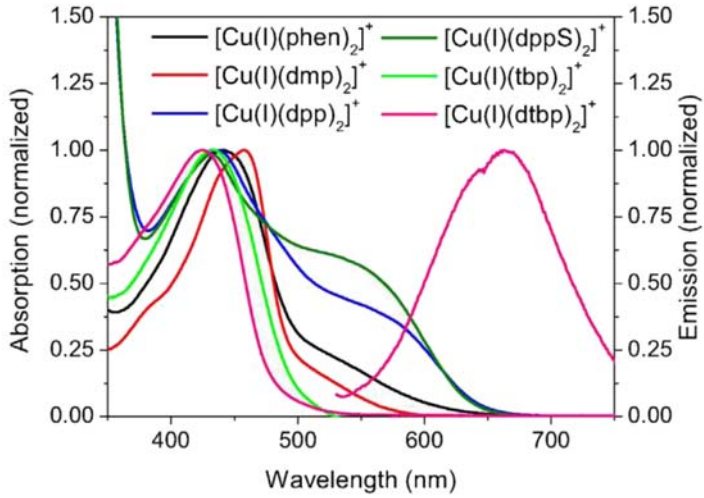

FIG. 10.3 Example of the absorption and emission spectra features of $[Cu(N^{\wedge}N)_2]^+$type complexes. *Adapted from Mara, M.W., Fransted, K.A., Chen, L.X., 2015. Interplays of excited state structures and dynamics in copper(I) diimine complexes: implications and perspectives. Coord. Chem. Rev. 282–283, 2–18. With Permission.*

The main electronic transitions in $[Cu(N^{\wedge}N)_2]^+$complexes as well as their accompanying structural distortions are pictorially represented in Fig. 10.4. A photon absorption matching the MLCT bands leads to an electronic transition from the GA (S_0) to the FC state S_2 (instead of S_1) due to the general transition forbiddance. Besides, upon excitation into the high-lying FC ^{1}MLCT states, minor $^3MLCT_{flattened}$ state can be generated via ISC directly to triplet states bypassing the S_1 state, where the absence of flattening distortion enables large SOC and thus allows fast ISC (on a sub-picosecond timescale) (Zhang et al., 2018). Otherwise, the S_2 state relaxes to S_1 via IC (non-radiative decay) after around 45 fs. This process depends on the steric congestion around the metal center. If there are bulky groups in the ligand surrounding the metal center, S_1 would relax directly to the lowest triplet state ^{3}MLCT through ISC. If that is not the case, the S_1 state will suffer from a flattening in geometry within a timescale of approximately 660 fs, reaching a flattened $^1MLCT_{flat}$ state and then decaying to the $^3MLCT_{flat}$ state with a higher rate constant of $<$10 ps, followed by an emission process of around 50 ns from the triplet excited state to the ground state. In addition, the degree of distortion of the ^{1}MLCT state is vital for the rate constant of ISC since the SOC is controlled by orbital overlap between the copper ion and the chelating ligands (Lu et al., 2018). This later tends to decrease as the molecule flattens due to the symmetry change from D_{2d} (which has strongly coupled spin-orbital wavefunction overlap) to D_2, where the stabilized molecular orbitals (MOs) have reduced spin-orbital wavefunction overlap. Consequently, the ISC time constant, whose value is fundamental for the

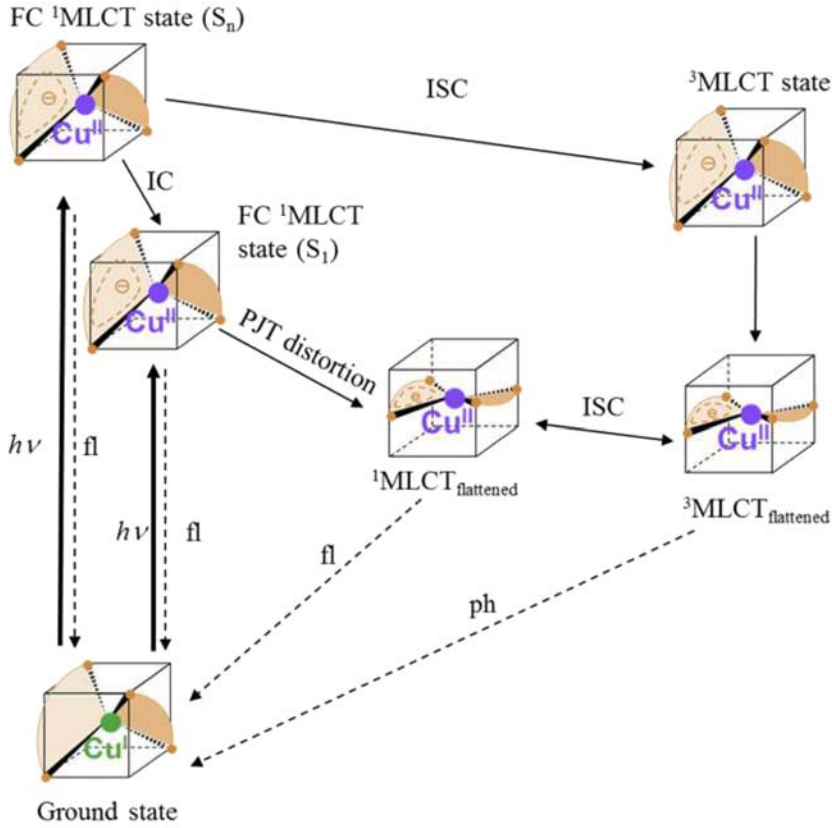

FIG. 10.4 General geometrical changes of Cu(I) complexes upon excitation into MLCT absorption bands. Radiative transitions (fluorescence (fl) and phosphorescence (ph)) are shown as *dashed lines* and non-radiative transitions as thin *solid lines*. *Adapted from Zhang, Y., Schulz, M., Waechtler, M., Karnahl, M., Dietzek, B., 2018. Heteroleptic diimine-diphosphine Cu(I) complexes as an alternative towards noble-metal based photosensitizers: design strategies, photophysical properties and perspective applications. Coord. Chem. Rev. 356, 127−146. With Permission.*

formation of the luminescent long-lived ^{3}MLCT, is a function of the angle between the two phenanthroline planes (Mara et al., 2015).

In summary, the overall dynamics of the MLCT state for several Cu(I) diimine complexes can be described within three time scales: (i) < 1 ps, corresponding to the Jahn-Teller distortion, or flattening, which is absent when the structural change is severely hindered, (ii) 320 ps, assigned to ISC, which is a function of the excited state geometry and increases as the flattening becomes more significant, and (iii) 1 ns to a few s, corresponding to ^{3}MLCT decay, which is determined by the direct interactions of Cu center and solvent, and depends on accessibility of solvent molecules to the metal center (Mara et al., 2015).

Among the non-emissive events, the flattening distortion, driven by the change in the formal oxidation state of the copper center (from Cu(I) to Cu(II)) is one of fundamental relevance. It has been demonstrated by light-initiated time-resolved X-ray absorption spectroscopy (LITR-XAS) that pentacoordinate exciplex formation leads to the deactivation of the excited state through non-radiative pathways. As consequence, it appears reasonable that steric factors are more important that electronic factors for reaching radiative long-lived deactivation (Armaroli et al., 2007; Mara et al., 2015). In this sense, the addition of groups to the phenanthroline ligandsat the 2,9 positions results inmuch longer excited-state lifetimes, as such substitutions help the ligand to shield the metal center by blocking the access to solvent molecules. Furthermore, it should be noticed that even though substitutions at the 2,9- positions are imperative for observing efficient luminescence, substitutions at other positions still have an effect on it. This result is interesting regarding Jahn-Teller flattening distortion, given that it can only be avoided, when extreme structural constrains are present (Mara et al., 2015) (Fig. 10.5).

Most of the structures of N-donor ligands, including phenanthrolines, recently reported for the preparation of homoleptic Cu(I) complexes are summarized in Fig. 10.6. These examples have been chosen to highlight structural diversity of the available ligands and the endless possibilities they

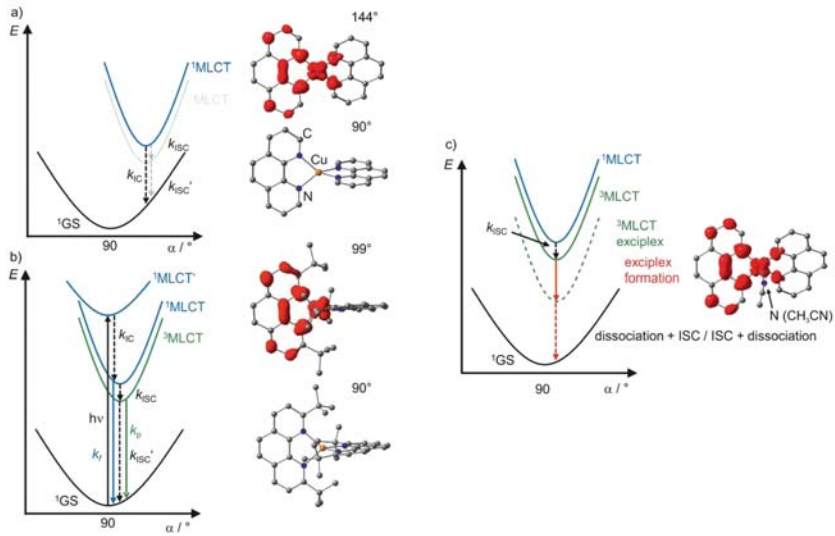

FIG. 10.5 Schematic potential energy surface diagrams of $[Cu(phen^{R2})_2]+$ complexes with relevant electronic states and photophysical processes of (A) $[Cu(phen)2]^+$, (B) $[Cu(phen^{tBu2})_2]^+$ and (C) exciplex formation exemplified by the acetonitrile adduct of $[Cu(phen)_2]^+$. *Adapted from Förster, C., Heinze, K., 2020. FIG. 10.6 Ligands used recently for the preparation of homoleptic Cu(I) complexes.

offer for the tuning of the photophysical performance of homoleptic complexes.

In an interesting example (Gimeno et al., 2020), prepared homoleptic complexes with asymmetrically substituted phenanthrolines (**1**−**2**), having an alkyl group at the 9-position (providing steric encumbrance to rise the excited state energy), and a phenyl group at the 2-position (allowing intramolecular π-stacking). Assessment of their excited-state properties indicated a relatively lower luminescence performance (compared with symmetrically substituted analogs), while an enhanced photo-oxidating power was observed.

Another interesting study showed by Livshits et al. (2020) the effect of trifluoromethylation at the 2- and 9-positions, as well as at other positions of the phenanthroline scaffold (**3**−**6**). In this case, they supported their results with DFT calculations and concluded that trifluoromethylation at the 2- and 9-positions of the phenanthroline changes the potential energy surface to favor interplanar angles of $\theta \sim 90$ degrees between both ligands by inhibiting the pseudo-Jahn-Teller distortions. The latter allowed to enhance the luminesce performance of the complex compared to the dmp complex. However, the phenanthroline were also susceptible to electronic effects caused by additional substitutions with trifluoromethyl groups, which decreases the luminesce performance, as the electron withdrawing nature of this groups affects the ability of the ligand to coordinate the metal center.

Apart from phenantrolines, other kinds of bidentate ligands have been used recently to obtain homoleptic compounds of Cu(I), and their photophysical properties have been assessed. In 2013, a family homoleptic complexes based on bis(aryl)acenaphthenequinonediimine (BIAN) (**7**−**12**) was synthesized by Papanikolaou et al. (2013), and their photophysical behavior has been analyzed (Papanikolaou et al., 2013; Ng et al., 2018). These complexes present some expected features like a distorted tetrahedral geometry, but also some remarkable and unexpected properties like a rhombically-distorted scare planar geometry, panchromatic light absorption (extending to the NIR region), and fast ISC from the ^{1}MLCT to the ^{3}MLCT (Kee et al., 2016; Ng et al., 2018). However, their luminescence is limited by the presence of low-energy lying ^{3}ILCT states, which decay to the ground state through non-radiative pathways (Papanikolaou et al., 2013). However, those kinds of complexes can also display emission properties from both ^{3}ILCT and ^{3}MLCT although the lifetime of the latter is very small comparted with their phenanthroline counterparts (Ng et al., 2018).

A new homoleptic complex based on a bis(indazol-1-yl)methane ligand (**17**) was prepared by Ferraro et al. (2020) displaying absorption for wavelengths below 410 nm and luminescence in the solid state. According to them, the observed luminescence was related to the population of triplet states like ^{3}MLCT and ^{3}LLCT. However, the complex presented low photoluminescence quantum yield due to non-radiative decay that seems to be related to the distortion of the coordination sphere toward square planar geometry.

Some examples of homoleptic copper complexes based in NP-type ligands have been reported recently. In the first case, a rare example of an emissive phosphaalkene (**18**) copper complex was reported by Clausing et al. (2020). Though the complex resulted weakly emissive, they used theoretical and spectroscopic studies to support an acceptor character of the ligand, whose complex displayed absorption in the UV-VIS region with LLCT and MLCT transitions. However, the lifetime of the excited state was about 9 ns upon irradiating into the MLCT band as consequence of a complex dynamic behavior of the compound in solution as indicated by NMR studies. Another example of luminescent Cu(I) homoleptic complexes with an NP-type ligand was also reported by Giereth et al. (2020). They synthetized a series of phosphinooxazasoline (phox) ligands (**16**−**22**), which could be obtained in a two-step procedure. These complexes resulted emissive in the solid state but only slightly emissive in solution. Moreover, supported by TD-DFT calculations and time resolved emission spectroscopy, the emission was assigned to a ^{3}MLCT excited state. Interestingly, the luminescent properties of the complexes appeared to be related to the chirality of the ligand. However, the MLCT states underwent a strong flattening distortion, which could not be avoided by changing the size or number of the substituents.

Despite of being recently known, the photocatalytic activity of homoleptic Cu(I) complexes has been widely reviewed during the last 10 years (Paria and

Reiser, 2014; Hossain et al., 2019; Nicholls and Bissember, 2019; Zhong et al., 2020; Sandoval-Pauker et al., 2021). Due to their unique photo-redox properties, these compounds have been used as photocatalysts or photosensitizers in different atom-transfer radical addition reactions (ATRA) (Pirtsch et al., 2012; Bagal et al., 2015; Ng et al., 2018; Nicholls et al., 2019), allylations (Pirtsch et al., 2012), coupling of carbazoles with alkyl iodides (Bissember et al., 2013), and others (Sandoval-Pauker, 2021).

10.4 Heteroleptic Cu(I) coordination compounds

The systematic study of Cu(I) heteroleptic complexes started in the same place as for their homoleptic McMillin et al. (1977) who fi congeners. It was also McMillin et al. (1977) who first reported the interesting luminescent properties of Cu(I) heteroleptic complex like [Cu[(N^N) $(PPh_3)_2$]. However, these studies were hampered by the coordination dynamics of these compounds in solution, having a strong tendency to undergo ligand redistribution reactions, which affected its luminescent performance (Forero Cortés et al., 2021). More than 2 decades later, the interest around heteroleptic diimne-diphosphine Cu complexes was reborn, when Cuttell et al. (2002) reported [Cu(N^N) (POP)] complexes with unprecedented excited-state lifetimes. From there on, numerous publications have reported the photophysical properties of different types of heteroleptic Cu complexes including [Cu(N^N) (N^N)'], [Cu(N^N) (P^P)], [Cu(N^P)L_n] and [Cu(N^O)L_n], and more recently [Cu(NHC)L_n] (NHC: N-Heterocyclic Carbenes).

In this account, before discussing the photophysical properties of some of those complexes, the important characteristics of heteroleptic Cu complexes have been discussed, especially those that set them apart from their homoleptic relatives.

The introduction of chelating diphosphine ligands allowed the improvement of photophysical and electrochemical properties of Cu complexes due to their tunable steric and electronic properties. This improvement has its origin in the three-dimensional arrangement (distorted tetrahedron) of the substituents around the P atoms, which (in contrast with diimide ligands) provides additional steric shielding to the metal center. Moreover, chelating diphosphines with wide natural bite angles can stabilize the tetrahedral geometry of the copper center, and at the same time, it can destabilize the square planar coordination environment. Furthermore, the σ-Lewis base character of the P atom (lone pair donation), along with its π-acceptor ability through π-back-bonding, makediphosphinesastounding coordination partners to Cu(I). As a consequence, [Cu(N^N) (P^P)] complexes display a distorted tetrahedral geometry in the GS, with a dihedral angle (DHA) defined by the N−Cu−N and P−Cu−P planes. It ranges from 78 to 89 degrees in the solid state, depending on the interaction of the ligands (e.g., π -stacking) and their steric hindrance, and with average Cu−N and Cu−P bond distances around 2.1 and 2.2 Å,

respectively. However, although stable heteroleptic complexes are predominantly obtained from [Cu(NˆN) (PˆP)] without sterically demanding substituents, heteroleptic complexes involving sterically crowded diimine ligands (commonly substituted at the 2,9-positions) are usually only stable in the solid state. Upon dissolution, a dynamic ligand exchange reaction takes place, resulting in the formation of homoleptic $[Cu(N\^N)_2]^+$ and $[Cu(P\^P)_2]^+$ species. This dynamic depends on the coordinating ability of the solvent, although its impact on the dissociating process has not been yet fully understood (Zhang et al., 2018; Forero Cortés et al., 2021) (Fig. 10.7).

Regarding their UV-vis absorption features, analogous to those observed for $[Cu(N\^N)_2]^+$ complexes, [Cu(NˆN) (PˆP)] complexes display intense high energy absorption bands in the UV region. In order to understand those absorption features from the electronic point of view, TDDFT calculations have been performed. According to these, the HOMO and HOMO+1 of $[Cu(N\^N)(P\^P)]^+$ complexes generally have a strong Cu-d and diphosphine ligand character with a small contribution from the diiminenitrogens. The LUMO and LUMO+1 are essentially the p orbitals delocalized over the diimine ligand with only minor (<10%) contributions from the copper atom and the

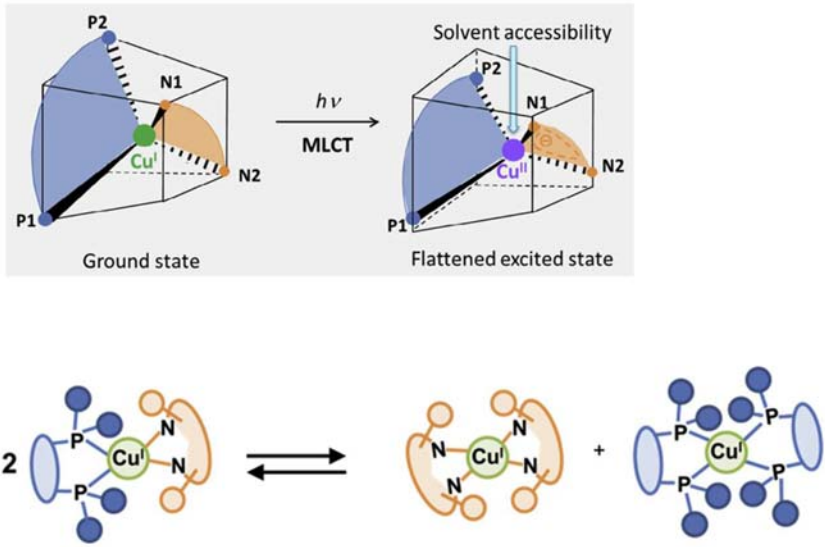

FIG. 10.7 Top: general geometries of heterolepticdiimine−diphosphine Cu(I) complexes in the ground state and flattened MLCT excited state. Botom: schematic representation of a possible ligand exchange reaction of heteroleptic $[Cu(N\^N)(P\^P)]^+$ complexes forming homoleptic species in solution. *Adapted from Zhang, Y., Schulz, M., Waechtler, M., Karnahl, M., Dietzek, B., 2018. Heteroleptic diimine-diphosphine Cu(I) complexes as an alternative towards noble-metal based photosensitizers: design strategies, photophysical properties and perspective applications. Coord. Chem. Rev. 356, 127−146. With Permission.*

diphosphine ligand. Therefore, the energetically lowest electronic transitions in $[Cu(N^{\wedge}N)\ (P^{\wedge}P)]^{+}$ exhibit a mixed MTCT, LLCT and ILCT character. However, the exact contribution of each orbital to the lowest electronic transition varies among individual systems. Moreover, calculation of the relative contribution to the frontier orbitals of complexes of the type$[Cu(I)\ (N^{\wedge}N)\ (DPEPhos)]^{+}$, showed that the contribution of Cu(I) to HOMOs is larger in complexes with bulky substituents in the vicinity of the copper center as well as in complexes bearing the DPEphos moiety. Moreover, the introduction of a diphosphine ligand decreases the energy levels of the corresponding orbitals (such as HOMOs) by virtue of its ability to accept electron density from the copper center, which results in an increased HOMO-LUMO gap and blue-shifted absorption bands.

Nevertheless, the strategy of increasing the transition dipole strength via tuning the π-conjugated system of the ligands, where the LUMO is localized has been effective to increase the molar extinction coefficient and to red-shift the absorption profile of the $[Cu(N^{\wedge}N)\ (P^{\wedge}P)]^{+}$ complexes (Zhang et al., 2018). However, it is worth to mention that the introduction of a chelating diphosphine ligand by itself is not enough to obtain luminescent complexes and the conjugated (aromatic) diimine donor is mandatory, since the use of aliphatic diiminies hampers the stabilization of the ^{3}MLCT state, as a result of the large structural relaxation during excitation (Yoshida et al., 2020).

In general, the excited dynamics of heteroleptic Cu(I) complexes differs from than that of their homoleptic counterparts (Fig. 10.8). Regarding their geometry, the change in the DHA for $[Cu(N^{\wedge}N)\ (P^{\wedge}P)]^{+}$ complexes is less pronounced than in the corresponding $[Cu(N^{\wedge}N)_2]^{+}$ complexes. In the latter, the change in the DHA (defined by the planes of the ligands) is more than 20 degrees, going from around 90 degrees in the GS to 58/67 degrees in the $^{1}MLCT_{flattened}$, while in the former, it could be as small as 12 degrees, depending on the bulkiness of the diphosphine ligand. Given the structure dependence of $^{1}MLCT_{flattened}$-^{3}MLCT transition on ISC, theoretical studies have reported that the rate of ISC increases as the structure of both states is more similar. As singlet-triplet splitting $E_{(S1-T1)}$ between those two states, is relatively small for most of the $[Cu(N^{\wedge}N)\ (P^{\wedge}P)]^{+}$ complexes, owing to the spatially separated frontier orbitals involved in these states; thus, a small exchange interaction integral. The thermal activated back-ISC has a higher probability to occur at higher temperature and luminescence can be observed as TADF, whose associated lifetime is shorter than that of phosphorescence at high temperatures. Furthermore, sterically congested $[Cu(N^{\wedge}N)\ (P^{\wedge}P)]^{+}$ complexes are efficient in suppressing the accessibility of the Cu center toward solvent molecules, avoiding the quenching decay. This results in strong and long-lived emissions, even in coordinating solvents (Zhang et al., 2018).

In addition, these complexes can be excited to a ^{1}ILCT state, followed by an ISC into the ^{3}ILCT. In such cases, the deactivation to the ground state

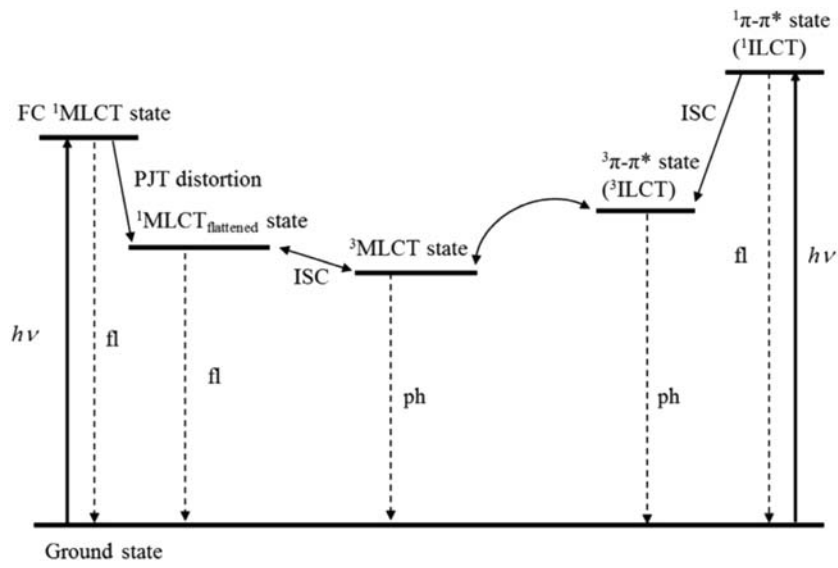

FIG. 10.8 Simplified photoinduced energetic transitions generally observed for heteroleptic Cu(I) complexes. *Adapted from Zhang, Y., Schulz, M., Waechtler, M., Karnahl, M., Dietzek, B., 2018. Rev. 356, 127–146. With Permission.*

occurs through both; radiative and non-radiative decay pathways. Excitation into the ILCT states for $[Cu(N^{\wedge}N)\ (P^{\wedge}P)]^+$ complexes can be achieved with high-energy photons. It should be noted that the energy splitting between ^{1}ILCT and ^{3}ILCT states is greater than that of the corresponding MLCT states (Fig. 10.8), which is due to the bigger spatial overlap of the involved frontier orbitals in ILCT states and thus, greater exchange interaction integral. However, this ^{3}ILCT emission tends to vanish at higher temperature due to the thermally activated interconversion between ^{3}ILCT and ^{3}MLCT states (Zhang et al., 2018).

In order to illustrate the concepts described so far, some examples extracted from the recent scientific literature will be discussed in the next subsections. These have been arbitrarily segregated into different groups depending on their ligand scaffolds: phenanthroline complexes, complexes with pyridyl-type ligands, complexes with N,P and N,O ligands and complexes with carbene ligands. This account is not exhaustive regarding the photophysical data of the complexes, which has been judiciously collected in several reviews and book chapters, nor give the overview of all the structures reported with luminescent properties, since it has been collected somewhere else as well. Instead, this section highlights some interesting examples reported in the last decade and discuss them in the light of conceptual and theoretical

knowledge about heteroleptic Cu(I), softening the transition, when switching between experimental and theoretical results.

10.4.1 Phenanthroline complexes

In 2012, the excited-state structure of cation (**23**) (Fig. 10.9) in their crystalline [BF_4] salt was determined by single-pulse time resolved synchrotron experiments with the modified polychromatic Laue method at both 180 and 90 K by Makal et al. (2012). In this study, they have pointed out that unexpectedly, in the crystalline form, the flattening distortion of this unsubstituted phenanthroline complex was very similar to the distortion experienced, when the ligand dmp is used instead. This predominant effect of the crystalline environment, clearly illustrates the fact that molecules in the solid state have different physical properties from those (isolated) in solution and that their properties heavily depend on the specific molecular environment. Nishikawa et al. (2015) reported the synthesis of new Cu(I) complexes bearing diop and dmpp or dmp ligands (**24** and **25**). The complex bearing the dmpp ligand (**24**) displayed a high quantum yield (0.38) and a long lifetime (26 μs). The latter is consequence of a positive effect coming from a small non-radiative decay rate of the excited states by introducing the diop ligand and phenyl groups at

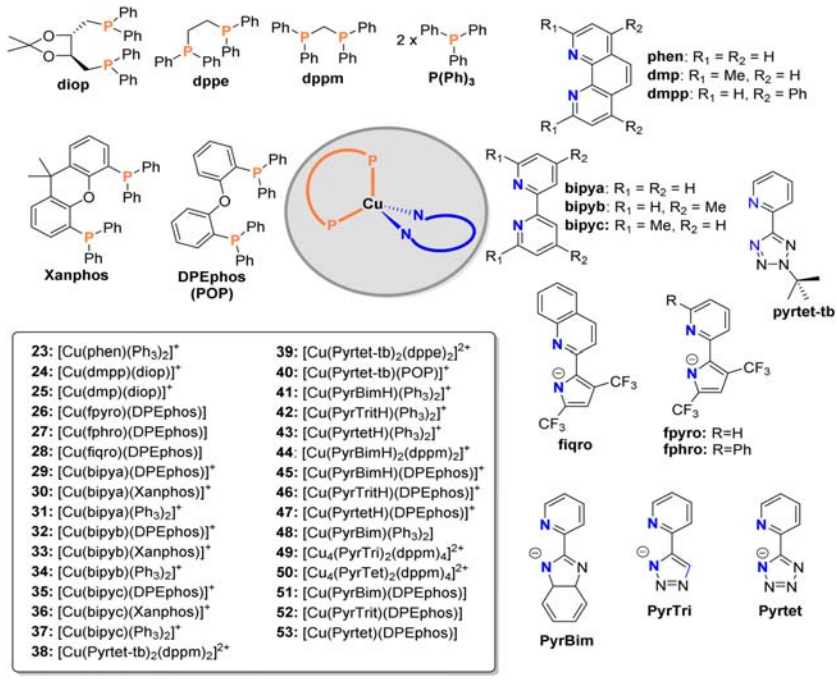

FIG. 10.9 Ligands used recently in the preparation of heteroleptic [Cu(N^N) (P^P)] complexes.

positions four and seven of the phenanthroline. Furthermore, TD-DFT studies indicated that the observed luminescence was consequence of MLCT and LLCT transitions where the π^* orbital of the phenanthroline is the acceptor.

10.4.2 Complexes with pyridyl-type ligands

Several complexes of different coinage metals using functionalized 2-pyridyl pyrrolide and DPEphos as coligand (**26**−**28**) have been reported, all with good emission quantum yield and lifetime above 20 μs. Hsu et al. (2011) found by using TD-DFT calculations that, in the lowest-lying electronic transition, the Cu(I) complexes show an appreciable metal d contribution, i.e., an MLCT transition, which allowed these complexes to exhibit a substantially larger rate of ISC and phosphorescence radiative decay rate constants than their Ag^I and Au^I counterparts. The latter, provided a proof that the direct involvement of the d orbital in the lowest-lying electronic transition plays a major role in inducing SOC.

The Cu(I) complexes based on mono- and di-phosphine ligands (DPEphos, Xanphos and PPh_3) and 2,2′-bipyridyl derivatives (**29**−**37**) were prepared by Andrés-Tomé et al. (2012). All the reported complexes displayed characteristic MLCT transitions and luminescence in the solid stated. However, the combination of rigid di-phosphine ligand and steric hindered bypridyl ligand substituted at the 6 and 6′ positions was necessary to attain luminescence in solution.

Examples of heteroleptic complexes using tetrazolyl pyridine ligands with chelating diphosphines including dppm, dppe and POP (**38**−**40**) were developed by Femoni et al. (2013). They showed by NMR an X-ray crystallography that while using dppm and dppe as ligands, bimetallic complexes were obtained. Regarding the luminescent properties, all the prepared compounds were poorly or non-luminescent in DCM solution at room temperature, but exhibited high quantum yields and emission lifetimes up to 22 μs in a KBr matrix at room temperature.

The coordination chemistry and the photophysical properties of a series of copper(I) complexes (**41**−**53**) with N^N ligands with a varying number of coordinating N-atoms like pyridine-benzimidazole, -triazole and -tetrazole, or their deprotonated analogs with PPh_3 or bidentate phosphines like dppm and DPEPhos were systematically studied. It was found that mononuclear cationic species are obtained with DPEPhos and PPh_3, but to obtain neutral complexes, the right combination of pyridine-amide and phosphine ligand must be chosen. The photophysical characterization of the substances had to be performed in the solid state because of the lack of stability or luminescence of some of them in solution. For the mononuclear complexes, DTF calculations suggested that the luminescent behavior of the cationic species is due to MLCT, but in the case of neutral complexes, there is also an additional ILCT input, suggesting that electronic effects of the pyridine-amide ligands play a major role in the

character of the luminescent transition. Therefore, the coordination chemistry, oxidation stability and emission properties of the neutral complexes are strongly controlled by the electronic effects of the pyridine-amide ligands, whereas in the cationic complexes mainly steric effects play a role in the coordination chemistry (Bergmann et al., 2018).

10.4.3 Complexes with NˆO, NˆP and SˆP ligands

Heteroleptic Cu(I) complexes using different diphenyl(2-pyridylmethyl) phosphane oxide ligands with both; PPh_3 and DPEphos as auxiliary ligand (**54**–**59**) were reported by Sun et al. (2010) (Fig. 10.10). They presented an example of heteroleptic luminescent complexes with a coordinating oxygen, where the complex containing PPh^3, displayed better performance than the one with the chelate DPEphos. Hight quantum efficiencies were reached as well as lifetimes over 1 μs were shown in solution. Moreover, the presence of MLCT transitions were demonstrated by electronic absorption and DFT calculations.

Osawa et al. (2013) reported a series of complexes of d^{10} coinage metals containing the monoanionic bidentate ligand diphenylphosphinobenzenethiolate, along with 1,2-bis(diphenylphosphino)benzene as ancillary ligand (**60**). Particularly, the copper complex displayed a distorted tetrahedral geometry with a DHA of 86.44 degrees, and green luminescence in the solid state (as well as in 2-MeTHF) at 77 and 293 K, with only a small red shift at higher temperature. The luminesce at room temperature was ascribed to TADF, as the quantum yield and the lifetime increased as the temperature was decreased. Furthermore, by using TD-DFT calculations, they assigned the luminescence to S → π* and π → π* (LLCT) transitions, and their contributions to the S_1

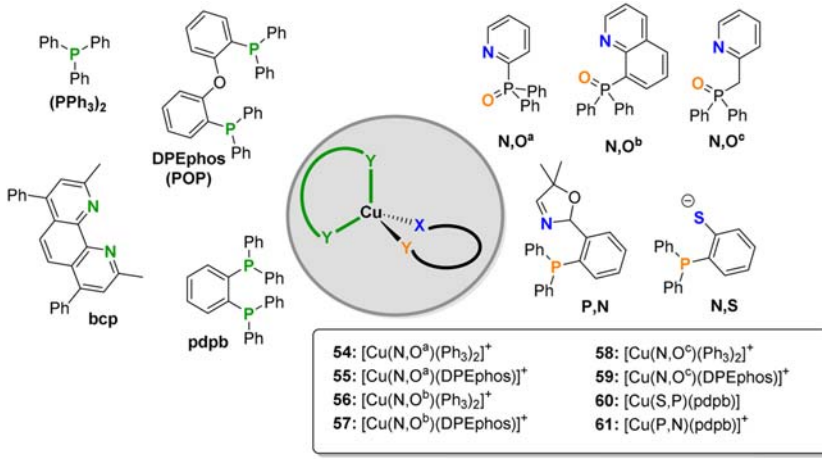

FIG. 10.10 Examples of heteroleptic complexes with bidentate NˆO, NˆP and SˆP ligands.

state were calculated to be 59% and 27%, respectively, while the contribution from MLCT transitions was only 4.6%. Hence, the thiolate ligand with electron-donating character reduced the contribution of metal orbitals to the HOMO of the complex, decreasing the MLCT character of their excited states. As a result, the origin of the TADF was an LLCT transition.

Giereth et al. (2017) reported the preparation of an heteroleptic complex using one of their phox ligands as well as bcp as ancillary ligand (**61**). They found that the heteroleptic complex displays improved absorption properties compared to the homoleptic phox complex, highlighting the importance of the diamine in the absorptivity of Cu(I) complexes. The latter conclusion was supported by TD-DFT calculations, where it was found that the LUMO and LUMO+1 MOs are mainly located at the bcp scaffold. Furthermore, the heteroleptic phox complex leads to an increase in absorptivity and a bathochromic shift of the main MLCT absorption compared to the heteroleptic reference complex $[Cu(bcp)(xant)]^{+}$.

10.4.4 Complexes with carbene ligands

An alternative strategy to avoid the flattening distortion in the excited state of Cu(I) emmiters has been the preparation of tricoordinated, trigonal planar complexes (Fig. 10.11), moving away from the "classical" tetracoordinated, tetrahedral geometries. The first example was presented by Krylova et al. (2010),who synthesized and characterized two different complexes bearing a monodentate N-heterocyclic carbene (NHC) ligand, 1,3-bis(2,6-diisopropylphenyl)imidazole-2-ylidene with an neutral phenanthroline (phem) or a negatively charged pyridyl-benzimidazole (pybim) as bidentate counterpart (**62** and **63**), obtaining a cationic and neutral complex, respectively (Fig. 10.12). They displayed phosphorescence in both; the solution and solid media, suggesting that solvent coordination is not the main quenching mechanism in liquid phase, and that molecular distortions may be the main quenching mechanism in solution.

In further investigations, the same group reported a series of luminescent [Cu(NHC) (N^N)] complexes, where the NHC ligand is principally involved in the excited state, demonstrating a wide range emission color tunability through modification of the carbene moiety. In addition, di(2-pyridyl)dimethylborate was used as ancillary ligand (**64**–**66**), being the first examples of luminescent heteroleptic Cu(I) complexes using a pyrazolyl-borate ligand. In the absorption spectra, the lower energy bands, which were not observed in absorption spectra of the precursors, were assigned to charge transfer (CT) transitions involving the NHC ligands.

It was also found that the modification of the carbene ligand allows the emission color to be tuned over 200 nm, from blue to orange-red, while retaining high emission efficiencies. However, even though these complexes displayed luminescence at room temperature in the solid state, their emission

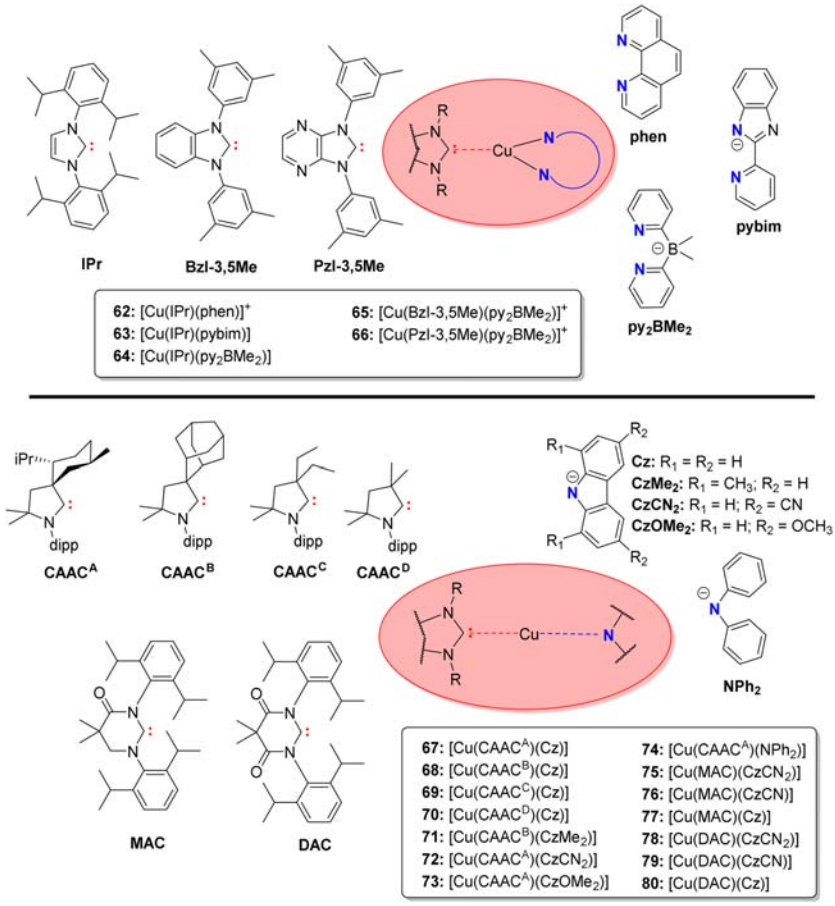

FIG. 10.11 Examples of heteroleptic Cu(I) complexes using N-heterociclyc carbene type ligands.

efficiencies in fluid solution were substantially lower. Furthermore, modest increase in emission lifetimes upon cooling were inconsistent with processes typically associated with TADF, suggesting instead that the emission arises from a state that is principally triplet in character. Finally, DFT and TD-DFT calculations suggested that the lowest-lying transition can be ascribed as (M + L)LCT admixed with intra-ligand $\pi \rightarrow \pi^*$ (of the pyrazolyl-borate ligand) (ILCT) character, whereas for the other complexes the transition is mainly metal-ligand to NHC ligand charge transfer ((M + L)LCT) (Krylova et al., 2014).

Hamze et al. (2019a) reported the synthesis and characterization of two series of linear heterolepticlinear biscoordinated Cu(I) complexes using common amides (N-carbazoyl) with different carbene ligands (Fig. 10.11).

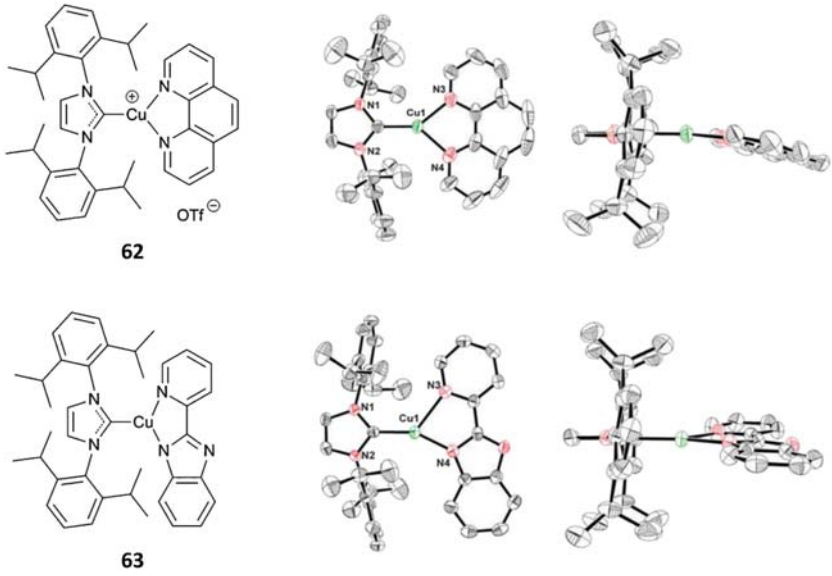

FIG. 10.12 Structural representation (left) and crystalline structures (rigth) of two planar Cu(I) complexes bearing an NHC ligand (IPr) with an neutral phenanthroline (phen) (**62**)or a negatively charged pyridyl-benzimidazole (pybim) (**63**). *Adapted from Krylova, V.A., Djurovich, P.I., Conley, B.L., Haiges, R., Whited, M.T., Williams, T.J. et al., 2014. Control of emission colour with N-heterocyclic carbene (NHC) ligands in phosphorescent three-coordinate Cu(i) complexes. Chem. Commun. 50, 7176−7179. With Permission.*

The first series made use of different cyclic (alkyl) (amino)carbene (**CAAC**) ligands with substituted cabazoyl ligands (**67−74**) as accompanying ligand. The second series of complexes consisted of monoamido-aminocarbene (**MAC**) and diamidocarbene (**DAC**) ligands with substituted cabazolyl moieties (**75−80**) as ancillary ligand (Shi et al., 2019). The complexes presented high luminescence efficiency in both; fluid and rigid media and short lifetimes. The main source of absorption and emission in the visible spectrum were strongly allowed amide-to-carbene ICT. The coplanarity of the two ligands demonstrated to be fundamental for the high performance of the luminesce wherein the metal d orbitals act as a weak electronic bridge between the parallel donor (N_{amide} $2p_z$) and acceptor ($C_{carbene}$ $2p_z$) orbitals; thereby, illustrating the potential for long-range p interaction. Furthermore, it was found that changing the metal center to obtain isoelectronic complexes does not change in a significative way neither the geometry, nor the electrochemical properties. However, photophysical properties like the CT bands in the absorption spectra and the emission lifetimes are affected (Hamze et al., 2019b). It was also postulated that the emission observed for those complexes is not by TADF but it is better described as thermally enhanced luminescence, where both the lower-energy and higher-energy states are highly emissive, albeit with

the lower state having a much longer radiative lifetime. Additionally, for the mentioned complexes, the luminesce is fully governed neither by the ISC rates between T_1 and S_1, nor by k_{fl} and k_{ph} from the respective S_1 and T_1 states, but by $\Delta E_{S1\text{-}T1}$ instead (Hamze et al., 2019a, b; Shi et al., 2019).

Importantly, like in the case of homoleptic complexes, the photocatalytic activity of heteroleptic Cu(I) complexes has been widely exploited and has been the subject of several reviews during the last 10 years (Paria and Reiser, 2014; Hossain et al., 2019; Nicholls and Bissember, 2019; Zhong et al., 2020; Sandoval-Pauker et al., 2021; Forero Cortés et al., 2021). Due to their remarkable photo-redox properties, long excited-state lifetimes and thigh stability, these compounds have been used as photosensitizers or photocatalysts in several transformations including ATRA reactions (Knorn et al., 2015) C−N cross-couplings (Kainz et al., 2016), pinacol-type couplings (Caron et al., 2019), reductions of aryl and alkyl halides, cyclization of aryl and alkyl iodides and arylation of (hetero)-arenes with aryl halides (Michelet et al., 2017), among others (Sandoval-Pauker et al., 2021). Remarkably, heteroleptic Cu(I) complexes have been also used (with relative success) in energy- and sustainability-relevant applications like water (proton) (Lennartson, 2017; Chen et al., 2017; Heberle et al., 2017; Giereth et al., 2019), and CO_2reductions (Gracia et al., 2020).

10.4.5 Miscellaneous Cu(I) coordination compounds

In addition to the already discussed structures containing one or two bidentate ligands in tetrahedral, planar or linear arrangements around the copper center, other kind of complexes with different ligand architectures have been also reported as photoactive. Among those examples, the most relevant include π-diborene complexes, several tridentate ligands, phthalocyanine and porphyrin.

A series of highly luminescent π-diborene complex of coinage metals were prepared by Bissinger et al. (2015),who obtained fluorescence quantum yields up to 100% in solution by suppression of phosphorescence (**81**, Fig. 10.13). Based on DFT and TD-DFT calculations, they supported this observation in the fact that metal atoms participate in a low degree in the excited states, resulting in a weakly active SOC leading to a low efficient ISC.

The luminescence properties of amine-bis(N-heterocyclic carbene) copper(I) and silver(I) complexes in solution and solid state were recently studied by (**82**, Fig. 10.13). The X-ray analysis of the complexes yielded a mononuclear structure with the three coordinating sites of the ligand attached to the metal center in the case of copper. Moreover, the absorption spectra of the complexes displayed three bands, associated with different type of transitions, and both these complexes were emissive in both; solution and the solid state. Finally, DFT/TD-DFT analysis suggested that the low-energy absorption and the emission properties were associated with a combination of both; MLCT

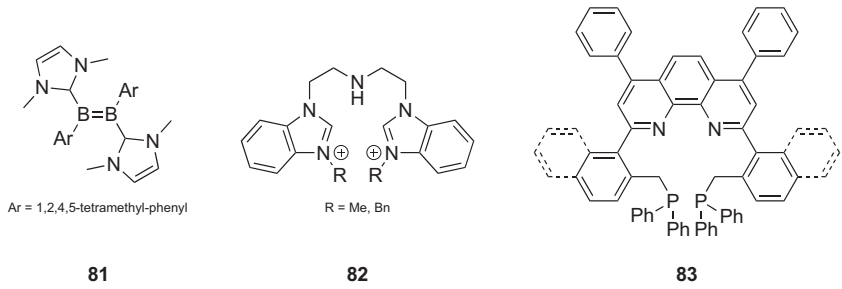

FIG. 10.13 Alternative ligands used for the preparation of luminescent complexes of copper and silver.

and LC from the metal atom and the amine, respectively, to the bis(N-heterocyclic carbene) moiety.

Chen et al. (2020) reported the preparation of two luminescent Cu(I) complexes with different tetradentate PNNP ligands, resembling an heteroleptic complex with a phenanthroline and a biphosphine (**83**, Fig. 10.13). In the six-step reaction, they managed to couple phosphines in 2- and 9-positions of the phenanthroline both; obtaining afterward copper(I) complexes with a distorted tetrahedral geometry around the metal center, as testified by X-ray crystallography. Although the ligands were also luminescent, the complexes presented a red shift compared to the "classic" $[Cu(P\hat{}P)\ (N\hat{}N)]^{+n}$ complexes. DFT/TD-DFT calculations revealed that complexes with this tetradentate ligands have a broader MLCT transition.

One example of the photochemical activity of Cu(I) complexes with tridentate ligands was recently reported (Fig. 10.14). In that work, Ahn et al. (2017) designed and synthesized a new copper-based photoredox catalyst, bearing a tridentate carbazolide/bisphosphine ligand, whose Cu(I) complex displayed photoluminescence. The complex was envisaged to yield the selective mono-alkyation of primary carbamates by unactivated secondary alkyl halides induced by irradiation under mild conditions. A key observation to reach this objective was that 2-bromo-4-phenylbutane quenches the luminescence of the excited state of copper complex. The mechanistic studies supported a pathway, where the photoredox catalyst generates an alkyl radical and a Cu(II) intermediate.

10.5 The entatic principle and its implication on the photophysical properties of Cu(I) complexes

As discussed previously, the geometry of Cu(I) complexes plays a fundamental role in their photophysical and photochemical properties. In this sense, a cumulative synthetic effort has been done to unravel the physical principles behind the luminescent behavior of these complexes. Nevertheless, the ability

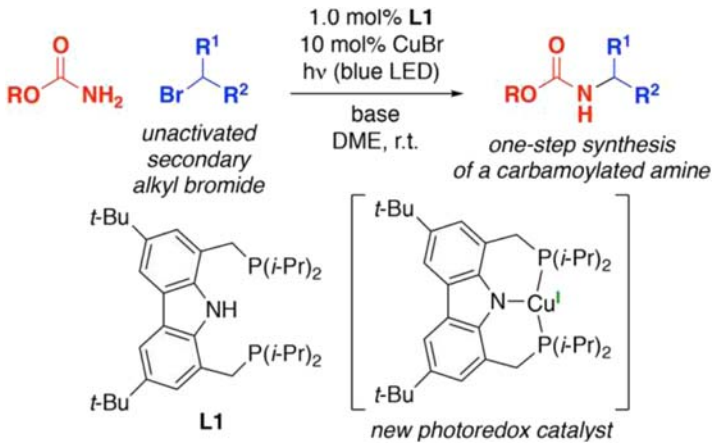

FIG. 10.14 Selective photocatalyzed mono-alkyation of primary carbamates by unactivated secondary alkyl halides using Cu(I) complexeswith chelating ligands. *Adapted from Ahn, J.M., Peters, J.C., Fu, G.C., 2017. Design of a photoredox catalyst that enables the direct synthesis of carbamate-protected primary amines via photoinduced, copper-catalyzed N-Alkylation reactions of unactivated secondary halides. J. Am. Chem. Soc. 139, 18101−18106. With Permission.*

to predict complex photoactivity based on structural parameters is still limited, and sometimes seems to be contradictory, when the same principles are applied to the different known coordination arrangements. For instance, from the available observations, it can be generalized, that controlling steric factors is more important that the electronic ones, as attested by complexes containing phenanthroline ligands, whose substituents at the 2,9-positions are fundamental to attain luminescence. However, it is still not possible to predict to which extent, this trend can be applied. Conversely, when considering heteroleptic complexes, the bite angle of the bisphosphine ligand and rigidity that this chelate confers to the complex seems to be the most important parameter.

In both cases, steric congestion, avoiding both deviation from the ideal tetrahedral geometry in the GS, and flattening distortion in the excited state, yields the best emission performance, regarding quantum yield and excited state lifetime. This behavior has been attributed to the inhibition of non-radiative deactivation pathways through exciplex formation. In this sense, the experimental data points out to a causal relationship: "The higher is the steric congestion around the copper center, the larger will be the lifetime of the excited species". This logical assumption is not absolute and has the limitations as discussed previously, then its applicability is surrogated to an specific context, mainly where complexes of the type $Cu[(N\^N)_2]^{n+}$ or $[Cu(P\^P)(N\^N)]^{n+}$ are used.

However, deepening in what steric congestion means for absorption-deactivation processes, one can arrive to the following conclusion: As copper changes from Cu(I) to Cu(II) after excitation by photon absorption, not

only its formal oxidation state changes, but also its preferred coordination geometry, yielding to an atomic reorganization from the Frank-Condon state to a more stable configuration (flattening distortion). Thus, if this process takes place at the limit, where both geometries are infinitely similar (due to steric congestion), then such reorganization would be avoided, and no energy will be invested there. As a consequence, at this point, the process would not find any restriction and its kinetics would be optimized according to the alternative pathways that demand a change in the geometry. This appears to be the same "reasoning" that evolution does in living systems according to Vallee and Williams (1968), who postulated that "*In all enzymes, the active site is constrained by the surrounding protein matrix to adopt a geometry similar to that anticipated for the corresponding transition state geometry of an unconstrained system. As a result, the reorganizational energy required to reach the transition state would be minimized and the reaction kinetics would be maximized and redox-active metalloenzymes with iron and copper at the active sites should represent prime examples of this entatic (constrained) state*" (Rorabacher, 2004). This principle is based on a pre-organization of the ligand sphere by a constrained geometry, which depends weakly on the oxidation state of the copper cation. Although pre-organization imposes an "energized" structure at the metal center, the metal is endowed with an activated geometric and electronic structure that can finely tune the complex for a specific function (Kohler et al., 2017; Dicke et al., 2018; Stroscio et al., 2019). Therefore, although not straightforward, an extension of this *entatic* principle could be done to understand the photophysical process in Cu complexes. This has been applied to the understanding electron transfer processes in Cu metalo-enzymes (where a transition state can be drawn), given that, in principle, an MLCT is rationalized as an intramolecular charge transference, where a transition state is not formed, but transient species instead.

Kohler et al. (2017) were the first to postulate that an *entatic* state was involved in a photophysical process. They found a linear correlation between the experimental GS redox potentials and τ_3. Afterward, they noticed a linear correlation between calculated GS-^{3}MLCT gap and the experimental E°s. Such correlation is maintained, when the calculated E°s or the $\ln(\tau_3)$ were used instead. They proposed that the ligand architectures of their synthesized complexes can be utilized to apply *entatic* state concepts to tune the ground state redox potential (E°) and thus, excited state lifetimes (τ_3). Furthermore, given the reorganization energies, they estimated the entatic energy contribution to the ground state for the 2,9-phenanthroline substitution by making use of the total inner sphere reorganization energies across their ligand set compared to one of the $Cu(phen)_2$ complex. Their estimated *entatic* was around 6−7 kcal mol^{-1}, which is similar to ground state *entatic* energies estimated for Cu enzymes.

A more thorough demonstration that the *entatic* principle could be extended to photophysical processes in Cu complexes was reported by Dicke

et al. (2018) In their work, a multi-method approach that featured time-resolved UV/Vis, infrared and X-ray absorption and optical emission spectroscopy was used to study a homoleptic biscoordinated guanidine-quinoline (**16**) copper complex with geometric restrains that allowed only small structural changes after photoexcitation. This led to very fast structural dynamics since all the involved states were structurally similar, owing to the pre-organization of the ligands around the metal. Although dynamics of the excited state were similar to those reported for phenanthroline complexes, including ^{3}MLCT and exciplex formation, they showed that the *entatic* principle is also applicable for spin-state control (Fig. 10.15). The reaction path from the Franck−Condon S_1 state over $S_{1,relax}$ into T_1 benefits from the *entatic* state principle because both extremes of the reaction coordinate (1 and 2 in their ground states) are structurally similar. The large amount of covalency of the guanidine−Cu bond and the structural constraint lower the degree of potential "flattening" of $S_{1,relax}$ and T_1 (an implication of the *entatic* state) and led to the rotation of the corresponding orbital required for efficient SOC.

Following this approach, Strocio et al. (2019) reported a combined experimental and computational methodology to quantify *entatic* contributions to photophysical process. Their approach is also based on the observation that

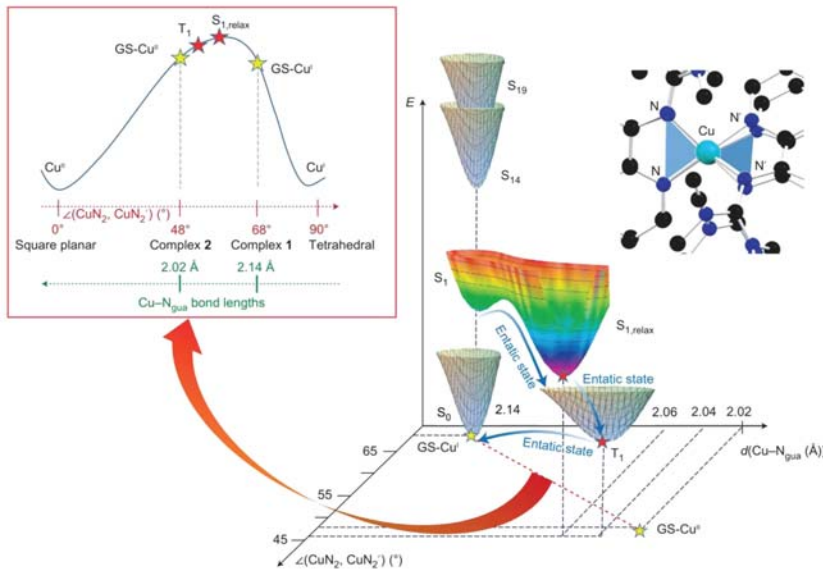

FIG. 10.15 Visualization of the "entatic" coordinates for the optical excitation of a homoleptic Cu(I) complex with ligand **16**. One axix illustrates thedihedral angle between the chelate planes and the other axis depicts the Cu−N_{gua} bond length. *Adapted from Dicke, B., Hoffmann, A., Stanek, J., Rampp, M.S., Grimm-Lebsanft, B., Biebl, F., et al., 2018. Transferring the entatic-state principle to copper photochemistry. Nat. Chem. 10, 355−362. With Permission.*

the natural logarithm of the ^{3}MLCT excited state lifetime ($\ln(\tau_3)$) for a range of Cu(I) bis-phen complexes correlate linearly with redox potentials (experimental and calculated), ground state inner sphere reorganization energies, excited state relaxation energies, and energy gaps (Fig. 10.16). Interestingly, most of the experimental data were subtracted from the scientific literature. In the first place, to determine the effect of the solvent in the same parameter, they compared the results obtained in the gas phase with those using the conductor-like polarized continuum model. Furthermore, they found a difference between the experimental and the calculated E°, which is attributed to the interactions between the oxidized state and some combination of solvent, electrode surface and counter ion that are not accounted by using continuum solvation calculation. The latter can affect the correlation between E° and $\ln(\tau_3)$ and thus, the quantification of *entatic* contributions. To avoid these differential oxidation-state interactions, the effects of the interaction with a weakly coordinating ligand (H_2O) were included in the calculations. Moreover, given that in addition to steric factors, the difference in electron-donating/withdrawing ability of the 2,9-substitutions in the phen ligands can affect the parameters mentioned before, the authors successfully decomposed steric and electronic contributions by using "H-capped" versions of the 2,9-substituents, which involves replacing the 2,9-group with H atom and keeping the geometry completely unperturbed otherwise.

In general, a linear correlation between $\ln(\tau_3)$ and the other parameters mentioned above was found, for 1 and 4 orders of magnitude changes in τ_3. As an illustrative example, looking at reorganization energies in 2,9-alkyl substituted phenanthrolines, a linear correlation between $\ln(\tau_3)$ and λ_i was

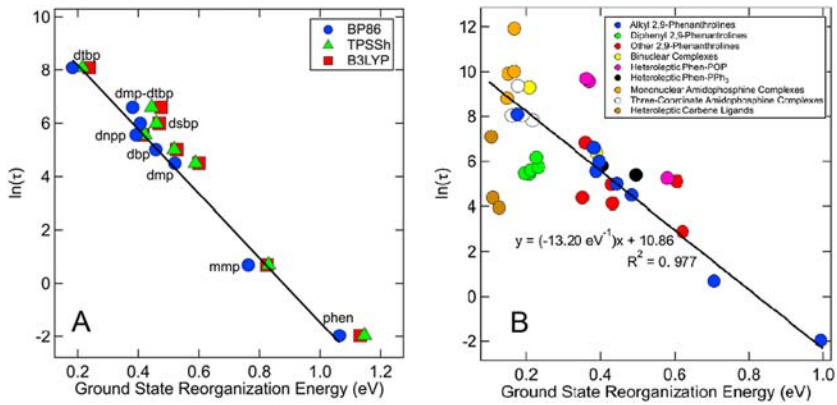

FIG. 10.16 Correlations between ln(τ)'s and ground state reorganization energies for (A) 2,9-disubstited phenanthrolines using different theory levels and (B) different classes of Cu(I) complexes. *Adapted from Stroscio, G.D., Ribson, R.D., Hadt, R.G., 2019. Quantifying entatic states in photophysical processes: applications to copper photosensitizers. Inorg. Chem. 58, 16800−16817. With permission.*

observed using different bases for the calculations (Fig. 10.16A). The model provides *entatic* contributions for one and four order of magnitude changes in τ of 4.3 ± 0.6 and 17.3 ± 2.2 kcal^{-1} mol, respectively, when differential oxidation-state contributions are not considered and 5.4 ± 0.5 and 21.7 ± 2.0 kcal^{-1} mol, when they are, indicating a small effect of them in the correlation. *Entatic* contributions provided by H-capped ligands (4.4 ± 0.7 and 17.7 ± 3.0 kcal^{-1} mol) were similar to those obtained from uncapped structures, indicating that the *entatic* contributions estimated using λ_i are largely due to sterics and further suggested that these play a more significant role in excited state lifetimes than electronic contributions. Finally, *entatic* contributions estimated using CPCM solvation approaches (15.7 ± 2.4 and 17.3 ± 2.2 kcal^{-1} mol), were similar to those in the gas phase, supporting that λ_i reflects geometric and steric contributions rather than solvation and electronic effects.

This analysis could be extended to other kind of Cu complexes (Fig. 10.16B). For instance, when heteroleptic $[Cu(phen)(POP)]^+$ were used, the linear correlation is maintained but the complexes display higher λ_i. As the changes in the dihedral angle are similar to those of 2,9-akyl substituted complexes, this effect seems to be due the increase in the covalent nature of Cu−P bonds relative to the Cu−N. On the other hand, in the case of linear complexes featuring an N-heterocyclic carbene and carbazolyl ligands (Fig. 10.16B), the observed reduction in the reorganization energy was not attributed to *entatic* contributions because of ILCT nature of the excited state and the small Cu contribution to it.

10.6 Silver complexes

10.6.1 Homoleptic Ag(I) coordination compounds

As show cased in the previous sections, the photophysics of tetrahedral Cu(I) complexes has been thoroughly studied, especially for homoleptic bisimine complexes (see Section 3.1). Comparatively, studies of analogous Ag(I) complexes of tetrahedral geometry are still very scarce. Pioneering reports on this topic were presented by Osawa and Hoshino (2008), who prepared the homoleptic complex with diphosphine ligands: $[Ag(dppb)_2]PF_6$ (Fig. 10.17) and investigated its excited-state properties.

Interestingly, the phosphorescence of this complex is strongly dependent on the matrix and conditions. It emits in the blue range ($\lambda max = 456$ nm) in a degassed 2-methyltetrahydrofurane solution at 77 K, while it emits orange color ($\lambda max = 670$ nm) at room temperature. Moreover, it displays blue emission, when embedded in polymethylmethacrylate films. Assuming that these emissions occur from an MLCT state, it was explained by evoking a flattening distortion from the tetrahedral ground state, leading to a red shift in the emission at room temperature since the flattened structure is more stable

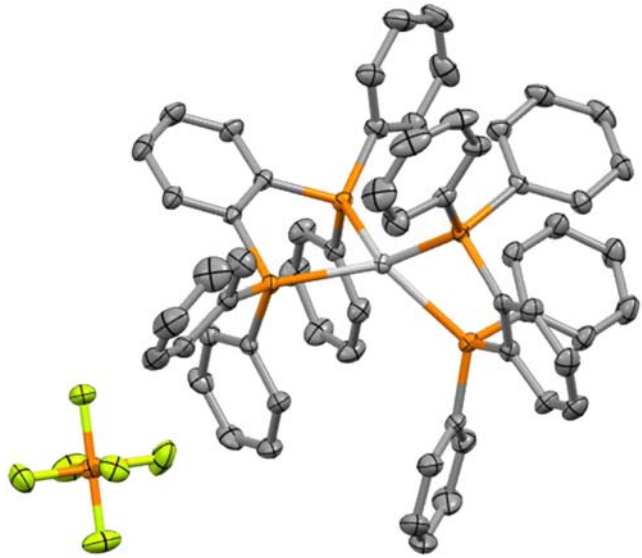

FIG. 10.17 Single-crystal X-ray structure of the $Ag(dppb)_2]PF_6$(CCDC 698226). Thermal ellipsoids are presented at 50% probability. *Adapted from Osawa, M., Hoshino, M., 2008. Photochemistry and photophysics of the tetrahedral silver(I) complex with diphosphine ligands: [Ag(dppb)2]PF6 (dppb = 1, 2-bis[diphenylphosphino]benzene). Chem. Commun. 47, 6384–6386. With Permission.*

than the tetrahedral in the excited MLCT state. This structural change was hampered in the solid phase, either in the frozen solvent at 77 K, or in the polymeric films, resulting in emissions from the tetrahedral state instead (Fig. 10.18).

Further investigations by Kaeser et al. (2014) on homoleptic Silver(I) bisphosphine complexes (along with their Cu(I) and Au(I) congeners) showed that complexes of the wide bite-angle POP (Fig. 10.10) displayed a distorted tetrahedral AgP_4 coordination geometry, in strong contrast with analogous copper and gold complexes, where only one POP ligand behaves as chelate, being the second coordinated through only one P donor in a trigonal geometry. Contrary to its dppb analog, the emission is attributed to a triplet MLCT state, where POP complexes display ligand-centered triplet excited states.

Virtually all Cu(I) and Ag(I) emitters possess some sort of distorted tetrahedral geometry in their ground state and their corresponding triplet MLCT states show some degree of square-planar flattening. Interestingly, there were no reports upto before 2019 describing square-planar d^{10}-emiters. Thus, it was not known that what would happen to planar Ag(I) complexes upon excitation, or if they would be luminescent. In an interesting report, Artem'ev et al. (2019) described for the first time the emission properties of Ag(I) complexes with a square-planar geometry. They answered these

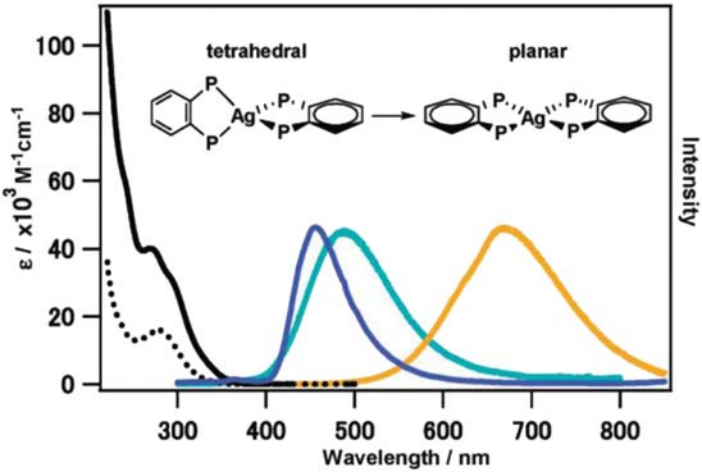

FIG. 10.18 Absorption spectra of ligand dppb (*dashed line*) and silver complex $Ag(dppb)_2]PF_6$ (*solid line*) in2-methyltetrahydrofurane and emission spectra ($\lambda_{exc} = 266$ nm) of the complex in polymethylmethacrylate film (light blue) and in 2-methyltetrahydrofurane (orange at 293 K, blue at 77 K). The inset shows the proposed flattening distortion upon light irradiation. The phenyl-groups on each ligand were omitted for clarity. *Adapted from Osawa, M., Hoshino, M., 2008. Photochemistry and photophysics of the tetrahedral silver(I) complex with diphosphine ligands: [Ag(dppb)2]PF6 (dppb = 1, 2-bis[diphenylphosphino]benzene). Chem. Commun. 47, 6384−6386. With Permission.*

questions by preparing and analyzing such Ag(I) square-planar complexes, reacting the ligand tris(2-pyridyl)phosphine oxide (Py_3PO) with different Ag(I) salts (Fig. 10.19).

From the three complexes prepared by these authors (**84**-**86**), only **84** and **85** were thoroughly characterized, as co-crystals of **86** readily decomposed during the measurements. Both complexes display yellow emission at 300 K, with an interesting thermochromic behavior, turning the emission red-orange at 77 K. The novel Ag(I) square planar complexes showed very short phosphorescence lifetimes (compared to their tetrahedral congeners) of only 5−6 μs at 77 K. Theoretical calculation suggest that the S_1 state has ^{1}MLCT nature; thus being responsible for the fluorescence. Interestingly, the S_1 state readily relax via spin-forbidden inter-system crossing (ISC) to the T_1 state, due to the small energy gap (46 meV) resulting from the structural similarity between these states. After the fast ISC, radiative deactivation in the microsecond scale results in phosphorescence emission. The thermochromic effect has not been clearly rationalized.

10.6.2 Heteroleptic Ag(I) coordination compounds

Just as in the case of homoleptic Ag(I) complexes, most of the reported accompanying ligands are chelating phosphines, heterocyclic nitrogen donors

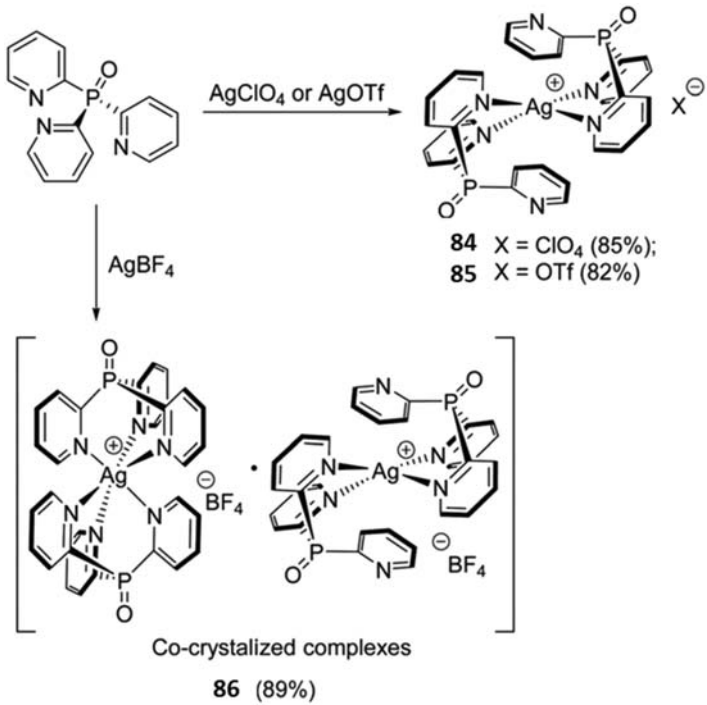

FIG. 10.19 First preparation of luminescent Ag(I) square-planar complexes. *Adapted from Artem'ev, A.V., Ryzhikov, M.R., Berezin, A.S., Kolesnikov, I.E., Samsonenko, D.G., Bagryanskaya, I.Y., 2019. Photoluminescence of Ag(I) complexes with a square-planar coordination geometry: the first observation. Inorg. Chem. Front. 6, 2855–2864. With Permission.*

and combinations thereof. Among the few reports dealing with these types of complexes, the studies by Igawa et al. (2012) dealing with heteroleptic diphosphine emitters are noteworthy. They prepared the homoleptic complex $[Ag(L)_2]PF_6$ (**87**), and the heteroleptic complexes $[Ag(L)(L_{Me})]BF_4$ (Fig. 10.20, **88**)and $[Ag(L)\text{-}(L_{Et})]BF_4$(L = 1,2-bis(diphenylphosphino)benzene (**89**) (L = dppb, L_{Me} = 1,2-bis[bis(2-methylphenyl)phosphino]benzene, L_{Et} = 1,2-bis[bis(2-ethylphenyl)phosphino]benzene)and studied their photophysical properties at room temperature.

These complexes include dppb-derived ligands containing alkyl substituents at the ortho positions of the peripheral phenyl groups, resulting in congested, rigid environments around the metal center. The homoleptic complex **87** displays strong blue luminescence in degassed 2-methyltetrahydrofurane solution at 77 K, while it weakly emits in the orange region ($\lambda max = 670$ nm) at room temperature. This large red shift is indicative of a large geometry change upon excitation, due to flattening distortion from the pseudotetrahedral ground state. Conversely, heteroleptic

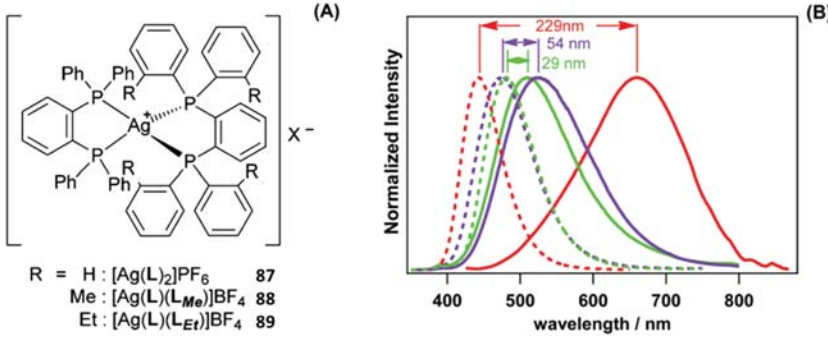

FIG. 10.20 Homoleptic and heterolepticdiphosphine Ag(I) complexes reported by Osawa and co-workers (A) and corrected emission spectra ($\lambda_{exc} = 300$ nm) of complexes **87**(red [light gray in print version]), **88** (purple [dark black in print version]), and **89** (green [light gray in print version]) in degassed 2-methyltetrahydrofurane solution at 77 K (*dashed lines*) and 293 K (*solid lines*) (B). *Adapted Igawa, S., Hashimoto, M., Kawata, I., Hoshino, M., Osawa, M., 2012. Photoluminescence properties, molecular structures, and theoretical study of heteroleptic silver(I) complexes containing diphosphine ligands. Inorg. Chem. 51, 5805−5813. With Permission.*

complexes **88** and **89**, display a bright green phosphorescence with only slight shifts at 77 K, of 54 and 29 nm, respectively. This green phosphorescence is attributed to a mixture of σ - π * and π - π* transitions, as theoretical studies. Moreover, with the help of time-dependent DFT calculations, they have confirmed that the steric congestion caused by the alkyl substituents in the ligands effectively prevents the flattening of the tetrahedral geometry upon light absorption. The introduction of interligand steric interactions is a general approach to improve the luminescence of d^{10} emitters, both in the solid state as well as in solution.

Another interesting series of heteroleptic complexes was reported by Hsu et al. (2011) using the chelating biphosphine POP and functionalized 2-pyridyl pyrrolide (**90** and **91**, Fig. 10.21). They studied the nature of their emissive states as well as the structure-photophysics relationships compared to their Cu(I) analogs (**26**−**28**). They concluded that, compared to their lighter copper congeners, the metal center possess a higher oxidation potential due to the low-lying d orbital, resulting in insignificant contributions of MLCT in their lowest singlet and triplet excited states. Thus, in these heteroleptic Ag(I) complexes, both S_1 and T_1 states have mainly a ligand-centered ππ* character. Hence, upon light absorption, since the S_1 state is dominated by the ππ* contributions, there is not a marked geometry deviation from its ground-state tetrahedral structure. This was confirmed experimentally by the very small emission shift observed for these complexes, when recorded at 77 K and at room temperature (Fig. 10.21). This is in strong contrast with other tetrahedral Ag(I) emitters, as those described at the beginning of this section, where the flattening distortion upon excitation is imminent. This apparent discrepancy only provides another example of the critical role played by the ligand

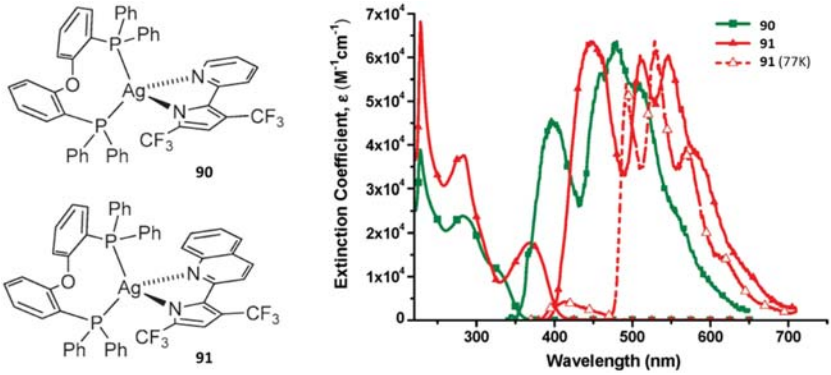

FIG. 10.21 Heteroleptic Ag(I) complexes bearing POP chelates and pyridyl/pyrrolide ligands and their absorption and normalized emission spectra in CH_2Cl_2 solution at RT 77 K. *Adapted from Hsu, C.W., Lin, C.C., Chung, M.W., Chi, Y., Lee, G.H., Chou, P.T., et al., 2011. Systematic investigation of the metal-structure–photophysics relationship of emissive d10-complexes of group 11 elements: the prospect of application in organic light emitting devices. J. Am. Chem. architectures on determining the photophysical properties of luminescent metal complexes.

Another impressive example of fine-tuning of the photophysical properties of heteroleptic Ag(I) complexes by varying the interligand steric interactions was provided by Shafikov et al. (2017). They designed a series of complexes containing the chelating biphosphane P_2-nCB (bis(diphenylphosphine)-nido-carborane) and different phenanthroline derivatives with different substituent at their 2,9-positions (**92–94**, Fig. 10.22).

The strongly donating P_2-nCB ligand is necessary to provide contribution of d orbitals (of the metal) to the HOMO and HOMO-1 molecular orbitals, being these located at the "phosphine side" of the complex. Thus, with the LUMO and LUMO +1 orbitals centered at the phenanthroline moiety, it is possible to have S_1 and T_1 states with a charge-transfer character (in contrast to other complexes discuses earlier in this section), which is prerequisite to an efficient TADF.

The different substituents at the phenanthroline scaffold have an electronic effect, influencing the radiative decay of the S_1 state, while, at the same time, increase the rigidity of the pseudotetrahedral geometry, minimizing the non-radiative relaxation. This results in boosting the photoluminescence quantum yield (Φ_{PL}) up to 100% for the most sterically congested complex (**94**).

10.7 Gold complexes

10.7.1 Au(I) coordination compounds

Along the series of d^1 degree complexes, those of Au(I) show the highest propensity to be coordinatively unsaturated, favoring aggregation through

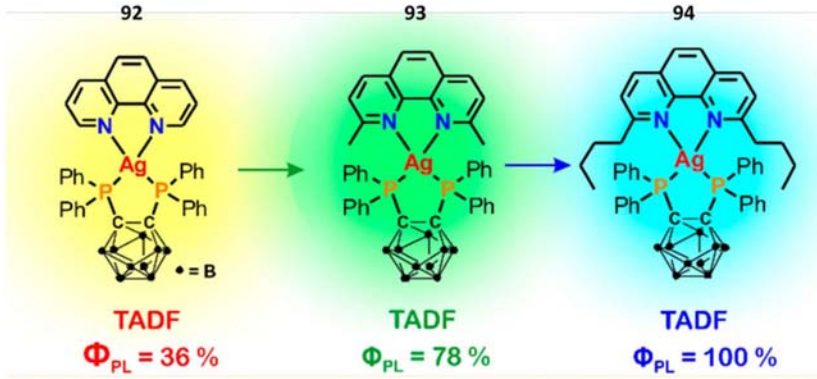

FIG. 10.22 Heteroleptic complexes with highly efficient thermally activated delayed fluorescence (TADF). *Adapted from Shafikov, M.Z., Suleymanova, A.F., Czerwieniec, R., Yersin, H., 2017. Thermally activated delayed fluorescence from Ag(I) complexes: a route to 100% quantum yield at unprecedentedly short decay time. Inorg. Chem. 56, 13274−13285. With Permission.*

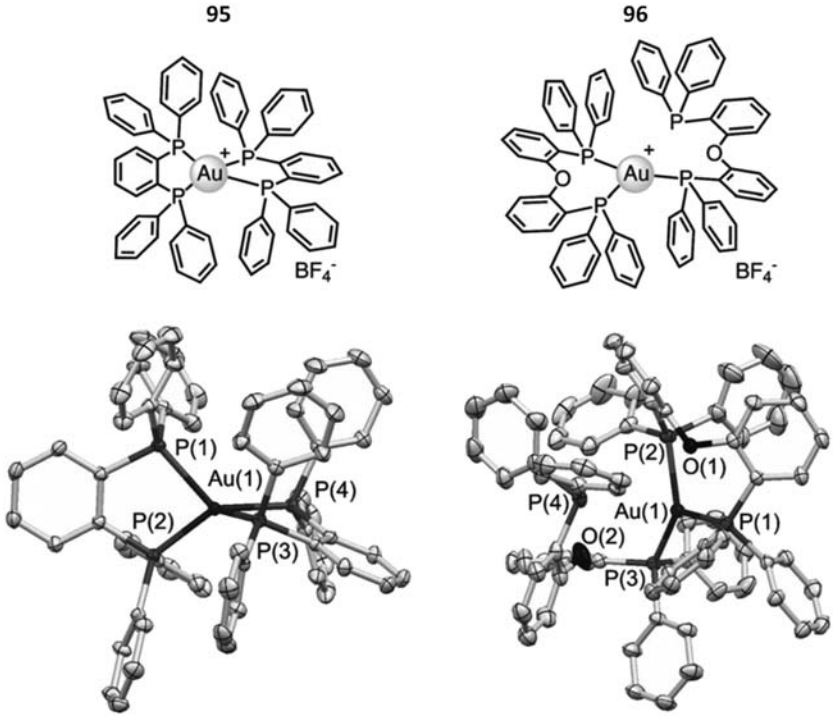
metallophilic interactions. This phenomenon results in new excited states for the aggregates, different to the "original" ligand-centered or charge transfer in the monometallic species (Lei et al., 2017; Seifert et al., 2020; Schmidbaur and Raubenheimer, 2020). In spite of this tendency, there are various fairly stable monometallic Au(I) complexes prepared using rigid chelating ligands, especially biphosphines and terpyridines. Pioneering reports of Kaeser et al. (2014) described the preparation of Au(I) homoleptic complexes of biphosphine ligands dppb (**95**) and POP (**96**), adopting the former expected pseudotetrahedralgeometry (like its copper and silver analogs), while the later displays a trigonal coordination geometry, probably due to the smaller van der Waals radio of the Au(I) cation, resulting in a more difficult "accommodation" of the two POP ligands, which have a wider bite-angle than dppb (Fig. 10.23).

Both complexes (**95**) and (**96**) have exited estates resulting from transitions of a non-bonding electron at the phosphorous atom to an antibonding π^* orbital at the phenyl substituents at the same atom. Importantly, the steric congestion provided by the diphosphine ligands is fundamental to guarantee the stability of these complexes in solution and retain its luminescence.

In a similar report, Hsu et al. (2011) compared the structural and photophysical properties of heterolepticd[10] complexes bearing phosphine and pyridyl/pyrrolide ligands, finding that, while Cu(I) and Ag(I) complexes display MP_4 distorted tetrahedral geometries, all Au(I) derivatives display essentially linear arrangements, with P−Au−N angles from 163.4 to 174.1 degrees, as exemplified by the complex complex Au(PPh3) (fphro) (fphro = 3,5-bis(trifluoromethyl)-2- (6′-phenyl-2′-pyridyl) pyrrolide) (**97**) in (Fig. 10.24). The lower-lying S_1 state of these type of Au(I) complexes possess $\pi\pi^*$ ligand-centered character and hence, it is not expected to undergo structural



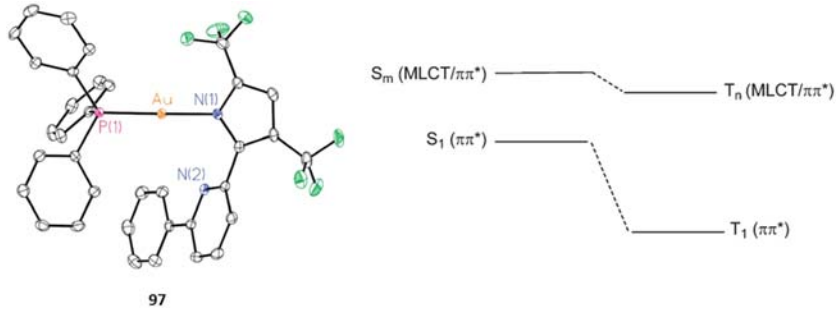


FIG. 10.23 Homoleptic Au(I) complexes of biphosphineligandsdppb (**95**) and POP (**96**). The X-ray structure of the corresponding cations is presented with thermal ellipsoids at the 50% probabilitylevel. *Adapted from Kaeser, A., Moudam, O., Accorsi, G., Séguy, I., Navarro, J., Belbakra, A., et al., 2014. distortions upon excitation (Fig. 10.24). This was confirmed experimentally by the observation of very similar emission wavelengths for these complexes at room temperature and at 77 K. Interestingly, all the prepared complexes were monomeric, with no hints of intermetallic interactions.

An important class of linear luminescent Au(I) complexes are organometallic compounds with the general backbone C−Au-E (E = N or P), being carbon ligands normally fluorinated aryl moieties, alkynyl rests or N-heterocyclic carbenes (Fig. 10.25) Langdon-Jones and Pope (2014). The simple complex [Au(C_6F_5) (η^1-terpy)] (**98**) exhibits green luminescence in the solid state at 77 K, with a lifetime of the excite state in the nanosecond range, suggesting a fluorescent emission from an LMCT state. In solution (in acetonitrile) at room temperature, this complex undergoes a dissociative equilibrium, releasing its terpyridine ligand.

Recently, Hamze et al. (2019a,b) reported the systematic study of the photophysical properties of linear d^{10} complexes containing an amide donor

97

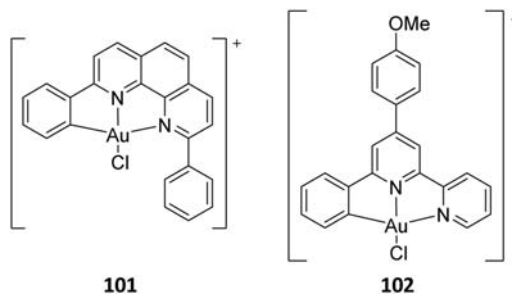
98 99 100

FIG. 10.25 Some examples or emissive linear Au(I) organometallic complexes.



(N-carbazoyl) and two different carbene ligands. They observed that Cu, Ag and Au complexes (**99** and **100**) have nearly the same structure, with C-M-N bond angles close to 180 degrees. Interestingly, the luminescence of these linear complexes does not have the same nature as in other emissive metal complexes where the metal center is a redox active donor in the ground state, and the emissive states are generally of MLCT character. In this case, the metal center is "redox innocent" and behaves only as a channel to modulate the electron transfer between the two redox active C- and N-ligands.

10.7.2 Au(III) coordination compounds

Comparedto their isoelectronic Pt(II) congeners, there are relatively few reports of luminescent Au(III) complexes, mainly due to their orbital situation. Au(III) compounds have low-lying $5d_{x^2-y^2}$ anti-bonding orbitals, with once populated, can easily undergo non-radiative decay to the singlet ground state. Thus, to achieve long-living emissive excited states, the energy of these

orbitals needs to be increased over the one of potentially emissive IL or MLCT states (Wing-Wah Yam and Chung-Chin Cheng, 2007; To et al., 2013). A common strategy to raise the energy of *d-d* ligand field states is the introduction of good σ-donating ligands, as the metal center is rendered more electron-rich. Following this method, pioneering reports for the preparation and characterization of a series of cyclometallated Au(III) chlorides **101** and **102**, containing chelating CNN ligands (Fig. 10.26) have been described (Chan et al., 1994; Liu et al., 1995). These square-planar complexes were emissive both in the solid state (at 77 K) and in liquid solutions at room temperature with excited-state lifetimes in the microsecond range. Interestingly, the high excited state reduction potential of **101** ($E^{\circ *}(Au^{III/II}) = 2.2$ V versus NHE) was exploited for the photooxidation of 1,4-dimethoxy benzene under visible light in THF (Chan et al., 1994). Moreover, complex **102** showed a high binding to calf-thymus DNA, effectively quenching and blue-shifting the complex emission by intercalation (Liu et al., 1995).

Au et al. (2009) reported the first introduction of N-heterocyclic carbene (NHC) ligands to Au(III) complexes (**103**), capitalizing on the high stability and good electron-donating features of these popular ligand class. These complexes displayed vibronic-structured emissions spectra, which was attributed to intraligand ππ* states. Even though the nature of the accompanying NHC ligands did not affect their photophysical properties, its presence was fundamental to achieve enhanced luminescence (Au et al., 2009). Similar compounds including an extended conjugation on the chelate (**104**) were later reported by Che et al. (Fig. 10.27) (To et al., 2012). Compared to the Yam complexes (**103**), Che's emitters (**104**) possess higher emission quantum yields, and much higher triplet excited state lifetimes. These improvements are attributed to the rigidity of the extended p-system at the cyclometallated ligand, resulting in a much lower structural distortion upon excitation. With the new set of enhanced photophysical properties, these complexes (**104**), were able to serve as photocatalysts for the dehydrogenation of secondary amines, as well as for the cyanation of isoquinolines under aerobic conditions.

101 **102**

FIG. 10.26 Structure of the cation of cyclometallated Au(III) chlorides.

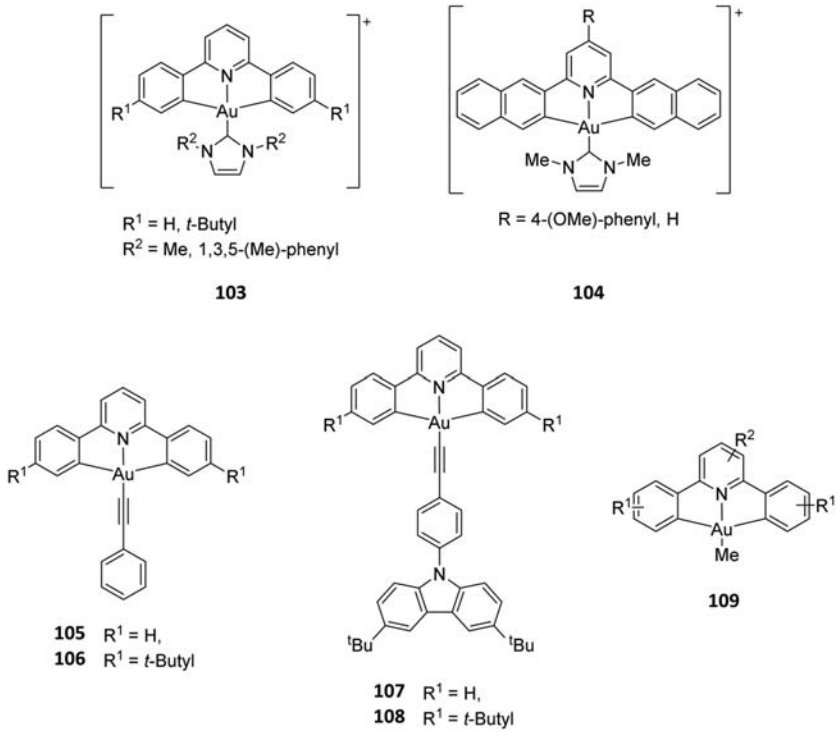


FIG. 10.27 Organometallic Au(III) complexes featuring cyclometallated ligands.

The potential of Au(III) as photocatalysts/photosensitizer was further exploited by Yu et al. (2016) reported the successful use of neutral bis-cyclometallated Au(III) complexes bearing akynyl ligands as light-harvesting materials in the production of hydrogen from water. The system used complexes **105**−**108** (Fig. 10.27) as sensitizers and cobalt or rhodium-based proton-reduction catalysts, with triethanolamine as sacrificial reductant. The high quantum yields (up to 13.7%) and turn-over numbers (up to 1441.5) are analogous to other popular ruthenium and iridium photosensitizers. An increase in emission quantum yields and lifetimes (up to 40%) was observed, when the alkynyl ligand is replaced by an alkyl moiety (i.e., methyl, **109**). Thanks to the absence of low-lying π-orbitals, along with their strong electron-donor capabilities. These features avoid the population of LLCT and LMCT states and result in highly emissive, long-lived ^{3}IL state instead (To et al., 2017).

10.8 Conclusion

The struggles and challenges posed to mankind by the turn of the century, including growing energetic demands, depletion of natural resources,

pollution, etc. have led us to the search for alternative technologies to tackle these problems in a low cost and sustainable manner. Thus, mimicking the way nature harnesses energy from the Sun to fuel the thrive of life on Earth seems to be a reasonable starting point. To achieve this goal, it is necessary to understand the complex mechanisms behind light absorption and emission in metal complexes to apply these insights in the design of novel photoactive complexes amenable to the multiple applications related to the aforementioned tasks: solar energy conversion and storage, CO_2 valorization, water sanitation, sustainable chemical synthesis, etc. For this purpose, base metals are the most desirable candidates for this endeavor, alas, not all of them are suitable, considering the necessary stabilities, redox potentials and absorption properties. Copper stands out as (arguably) the most versatile contestant, as quickly noticed by many researches and thoroughly attested by a myriad of publications on the photophysical properties of copper compounds and their uses. This field, however, is far for exhausted, as every day new analytical tools are developed, calculation power is increasing, and ligand architectures are developed, assuring more exciting insights and applications of the photophysics and photochemistry of copper complexes for the years to come.

Chapter 11

Coordination compounds of lanthanides

Jean-Claude G. Bünzli
Institute of Chemical Sciences & Engineering, Swiss Federal Institute of Technology, Lausanne (EPFL), Switzerland and Department of Chemistry, Baptist University, Hong Kong S.A.R., People's Republic of China

11.1 The elements and their coordination chemistry

11.1.1 Lanthanides and rare earths (Bünzli and McGill, 2000)

Lanthanides (Ln) are a series of 15 metallic elements with atomic numbers 57 (La) to 71 (Lu) belonging to the group of rare earth elements (RE = Sc, Y, Ln). According to IUPAC nomenclature rules, they should be named "lanthanoids" but "lanthanides" (corresponding in principle to Ce−Lu) is still the most used designation for these silvery metallic elements and their compounds. Another name for lanthanides is 4f-elements since the series Ce−Lu corresponds to the progressive filling of the 4f orbitals. In the short form of the periodic table of elements, La is positioned in column 3 (Sc, Y, La, Ac) with Ce−Lu listed separately below for the sake of saving space. In the long form of the periodic table, Ln elements (group 3) are inserted between Ba (56, group 2) and Hf (72, group 4) with Sc, Y, and Lu forming a column to the left of Ti, Zr, and Hf (Fig. 11.1). This arrangement agrees better with the electronic and chemical properties of the corresponding elements.

The denomination "rare earths" is a bit abusive, since the abundance of some RE elements is larger than several other technological metals, such as silver or indium, and comparable to that of lead, for instance. The least abundant rare earth is radioactive promethium that is only found as traces in some uranium ores; the natural abundances of the other 4f elements in the earth crust span a large range, from 0.5 ppm for lutetium to 60 ppm for the most abundant, cerium. The term "rare earths" stems from the fact that while the RE content in specific minerals is relatively large (35−75 wt%), these minerals are rather dispersed into the rocks or sands, in which they are found. In addition, each RE mineral contains several elements, sometimes even the entire RE series, which necessitates lengthy separation processes. Resources

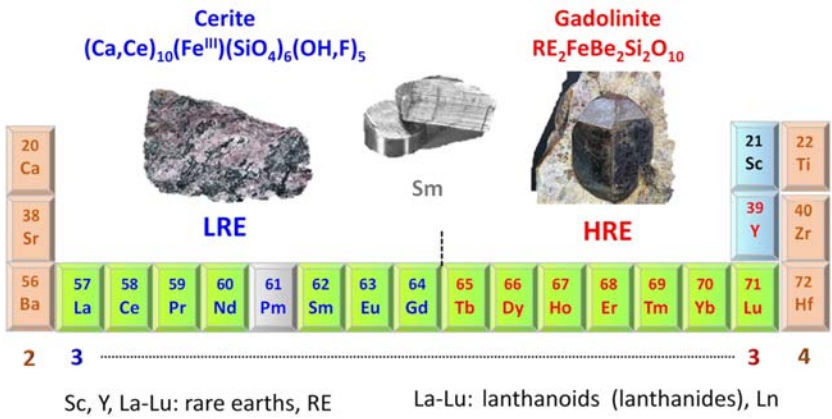

FIG. 11.1 Position of the rare earths and lanthanides in the long form of the periodic table. LRE stands for lighter rare earths and HRE for heavier rare earths. Inserts show two historically important minerals containing LRE (cerite) and HRE (gadolinite) as well as the silvery aspect of metallic samarium.

are found in many places around the world in Europe, Asia, Australia, North and South Americas. Remarkably, the total production of RE represents only a tiny fraction of all the metals produced worldwide, about 0.01%. In 2020, 243,000 tons of equivalent RE oxides were officially produced, of which about 58% was by China. Presently known rare earth reserves are large enough to cover more than 400 years of production at the current rate of extraction. Recycling is not yet substantial (a few % only), but will gain momentum, particularly for magnets which represent 20%−30% of the used RE tonnage. The main applications of rare earths are in catalysis, magnets, polishing powders and optical materials. As a matter of fact, rare-earth elements are presently providing irreplaceable functionalities in a wealth of daily-usage and high-technology items. Although essential elements, they often enter in minute quantities in a given commodity, e.g., about 200 mg in a smart phone.

11.1.2 Electronic configuration and oxidation numbers (Bünzli, 2020)

The most stable oxidation number of lanthanides is +3, with electronic configurations $[Xe]4f^n$ ($n = 0-14$), but oxidation number +2 exists for all lanthanides as well (except for radioactive and short-lived Pm), at least under the form of organometallic complexes. In the latter, two different electronic configurations have been evidenced, $[Xe]4f^n$ (Nd, Sm, Eu, Dy, Tm, Yb) and $[Xe]4f^{n-1}5\,d^1$ (La, Pr, Gd, Ho, Er, Lu) while Ce and Tb are borderline between the two configurations (MacDonald et al., 2013). In addition, cerium has also a quite stable +4 oxidation state with configuration [Xe] while this state is far

less reachable for the other ions except, until recently, in some praseodymium and terbium inorganic compounds; indeed, coordination chemistry of Pr^{IV} and Tb^{IV} is now starting to develop and might open unexpected perspectives in lanthanide chemistry and photophysics (Gompa et al., 2020).

A major feature of lanthanides is the shielding of the 4f orbitals by the $5s^25p^6$ subshells, which confers them an inner rather than a valence character. This, in turn, determines their unique chemical, magnetic and optical properties that are at the heart of so many practical applications. Indeed, lanthanide compounds have gradually become indispensable functional materials in a wealth of devices, ranging from cracking catalysts to high coercivity magnets and luminescent optical bioprobes. In this chapter, focus is put on the design and optimization of lanthanide luminescent coordination compounds.

11.1.3 Coordination chemistry (Bünzli, 2014)

Compared to d-transition elements, the coordination chemistry of RE elements had a slow start. Indeed these elements were long considered as minor by inorganic chemists. In water, their main oxidation number is +3 for the entire series and the shielding of the 4f subshell leads to similar chemical properties so that until the 1970s their coordination chemistry was thought to be uninteresting. But soon after, major developments in biosciences, namely the advent of Gd^{III}-based contrast agents for magnetic resonance imaging (MRI) and of chelates for time-resolved luminescent immunoassays considerably overturned this opinion. The advent of macrocyclic and supramolecular chemistry, as well as single molecule magnets, considerably contributed to increased interest for rare-earth chelates.

Several key factors govern RE coordination chemistry, particularly when considering $4f^n$ trivalent ions.

11.1.3.1 The ionic radius

The ions are large with radii of the order 100−120 pm that decrease more or less monotonically along the series, a consequence of increasing electronic density. This leads to the well-known "lanthanide contraction" but the overall contraction from La^{III} to Lu^{III} is only about 18 pm. Nevertheless, when ligands have small denticity, a coordination number change can occur along the series, usually around the middle of it.

11.1.3.2 The nature of the Ln-ligand chemical bond

Given the shielding of the $4f^n$ configuration, the chemical bonds are either ionic or of ion-dipole nature. Covalency is very small, usually in the range 3% −5% only. As a consequence, these bonds are non-directional and variable coordination numbers, ranging between 3 and 12 in the solid state, and coordination environments can be achieved by judicious choice of the ligands.

The types of complexes formed are commonly uniform along the series and their stability usually increases gradually with increasing atomic numbers; this is at clear variance with transition metal complexes, where covalent forces and ligand-field stabilization energies cause significant variations. In RE compounds, ligand-field splitting is the order of 100–500 cm^{-1} (1.2–6 kJ mol^{-1}) while it reaches 15′000 to 25′000 cm^{-1} (180–300 kJ mol^{-1}) for d-transition metal ions.

11.1.3.3 Hydration and chelate effect

The bonds between water and RE^{III} ions are very stable so that when complexing these ions in water the enthalpy change resulting from the replacement of H_2O with a ligand is often positive; as a consequence, complexes have to be entropy stabilized. In other terms, stable complexes usually require multidentate ligands (chelating agents), as illustrated by the stability constants of 1:1 complexes with acetates going up from $\log K \sim 2$ for simple acetate (denticity 2) to $\log K \sim 15–20$ for ethylenediaminetetraacetate ($edta^{4-}$, denticity 6). To avoid water competition, complexes with weak donors are preferentially synthesized in aprotic solvents.

11.1.3.4 Lability

Ligand exchange kinetics is very rapid with small-denticity ligands. For instance, water exchange rate is around $10^8–10^9$ s^{-1}. This leads to mixtures of differently coordinated complexes in solution and overall fractional coordination numbers. In water, the coordination number varies from 9 for La^{III} to 8 for Lu^{III}, with most of the change occurring in the middle of the series. The exchange rate strongly decreases with polydentate ligands: for an aminopolycarboxylate such as $[Lu(dtpa)]^{-2}$, k_{ex} is on the order of $\sim 10^{-1}$ s^{-1} ($dtpa^{5-}$ is diethylenetriaminepentaacetate, denticity 8), and it decreases further to $\sim 10^{-4}$ s^{-1} for the macrocyclic complex $[Lu(dota)]^-$ ($dota^{4-}$ is 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetate, denticity 8).

The coordination chemistry of RE^{III} ions is therefore subtle with steric effect having a predominant role so that these ions can be accommodated in many different environments. They preferentially bind to hard donor atoms, typically oxygen atoms or to the more polarizable nitrogen atoms. Classical ligands are carboxylates, aminopolycarboxylates, β-diketonates, and Schiff bases. Macrocyclic ligands such as crown ethers, aza-crown ethers, cryptands, calixarenes, porphyrins, or phthalocyanines have produced a wealth of quite stable and useful compounds in which the RE ions are encapsulated (Bünzli, 2003). As an extension to these classes of ligands, small macrocycles, e.g., tetraazacyclododecane (cyclen) or triazacyclononane, fitted with coordinating pendant arms have been extensively used to synthesise both stable and inert complexes. Moreover, self-assembly of carefully tailored ligands with RE ions allows the chemists to program specific functions into polynuclear

supramolecular structures such as helicates or polyhedral cages (Piguet and Bünzli, 2010). Finally, more extended structures are found in functional coordination polymers, in which the unique chemical, luminescent, and magnetic properties of RE ions can be exploited for various purposes.

11.2 Lanthanide luminescence (Bünzli and Eliseeva, 2011; Bünzli, 2015)

11.2.1 Energy levels

The electronic configuration of most lanthanide ions, $4f^n$, is usually well separated from the first excited configuration, $4f^{n-1}5\,d^1$, but, depending on the ion, the latter configuration can nevertheless play a role and lead to interesting spectroscopic applications. These two configurations generate an amazing number of electronic levels. Indeed, there are 7 f-orbitals and 5 d-orbitals so that there exist numerous ways of associating the n valence electrons with these orbitals, taking their spin into account. Each of these ways corresponds to a *microstate* $|\,(m_l\ m_s)_1\ (m_l\ m_s)_2\ \ldots.(m_l\ m_s)_n >$ where m_l values are the projections of the angular momentum of the electron ($\ell = 2$ and 3 for d- and f-orbitals, respectively) and m_s values are the projection of the spin moment ($s = \pm\ ^1/_2$); the number of microstates is called the *degeneracy* (or *multiplicity*) of the configuration. The degeneracy of a homogeneous configuration (e.g., $4f^n$) can be calculated from the following equation:

$$D_{4f^n} = \frac{(4\ell + 2)!}{n!(4\ell + 2 - n)!} = \frac{14!}{n!(14 - n)!} \tag{11.1}$$

A simple procedure for determining the various electronic levels is as follows (Fig. 11.2, top): (i) Interelectronic repulsion splits the configuration into *spectroscopic terms* $^{(2S\ +\ 1)}\Gamma$ defined by two quantum numbers, S (total spin momentum) and L (total angular momentum); $S = {}^1/_2$ times the number of unpaired electrons and Γ is a letter corresponding to L = 0 (S), 1 (P), 2 (D), 3 (F), 4 (G), 5 (H), and so on The quantities (2S + 1) and (2L + 1) are the spin and angular degeneracies, respectively, the overall degeneracy of a term being (2S + 1) × (2L + 1). (ii) Each term is then split by the spin-orbit interaction; Russel-Saunders scheme is commonly used for the sake of simplicity although the intermediate coupling scheme is more accurate for lanthanides. This interaction results in *spectroscopic levels* defined by an additional quantum number J (total angular momentum). The levels are denoted $^{(2S+1)}\Gamma_J$, with J = L + S, L + S −1, …. down to L - S and the degeneracy of each level is (2J + 1). (iii) Finally, each ^SL_J level is further split by the electric field generated by the surrounding ligands (*ligand-field splitting*, LF); the number of LF (or Stark) *sub-levels* depends on the symmetry around the lanthanide ion and the sub-levels are labeled according to their irreducible representations in group theory. An example is given for $Eu^{III}(4f^6)$ in an octahedral environment

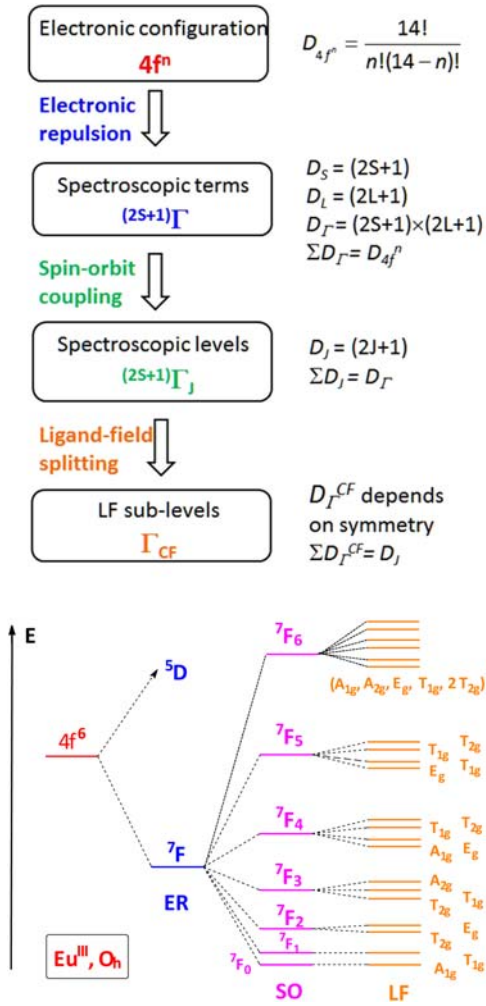

FIG. 11.2 (Top) flow chart for the determination of electronic sublevels of a $4f^n$ electronic configuration; *D* is the degeneracy (number of microstates). (Bottom) schematic representation of the splitting of the $Eu^{III}(4f^6)$ electronic configuration due to electron repulsion (ER, blue [dark black in print version]), spin-orbit coupling (SO green [light gray in print version]) and ligand field (LF orange [light black in print version]). Levels are not drawn to scale; approximate experimental energy differences are 2×10^4 cm^{-1} for ^5D-^7F, 5×10^3 cm^{-1} for $^7F_6$—$^7F_0$, and 3-5 $\times 10^2$ cm^{-1} for LF splitting.

in Fig. 11.2 (bottom) while the numbers of LF sub-levels for different point groups of symmetry versus the value of the J-quantum number are listed in Table 11.1. LF effects in lanthanide ions can be rationalized in terms of LF parameters, the number of which depends on symmetry (Görller-Walrand and Binnemans, 1996).

TABLE 11.1 Number of ligand-field sub-levels versus the value of quantum number J and the point group of symmetry.

		Integer J								
Symmetry	**Site symmetry**	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**
Cubic	T, T_d, T_h, O, O_h	1	1	2	3	4	4	6	6	7
Hexagonal	C_{3h}, D_{3h}, C_6, C_{6h}, C_{6v}, D_6, D_{6h}	1	2	3	5	6	7	9	10	11
Trigonal	C_3, S_6, C_{3v}, D_3, D_{3d}									
Tetragonal	C_4, S_4, C_{4h}, C_{4v}, D_4, D_{2d}, D_{4h}	1	2	4	5	7	8	10	11	13
Low	C_1, C_S, C_2, C_{2h}, C_{2v}, D_2, D_{2h}	1	3	5	7	9	11	13	15	17
Symmetry	Site symmetry	Half-integer J								
		1/2	3/2	5/2	7/2	9/2	11/2	13/2	15/2	17/2
Cubic	T, T_d, T_h, O, O_h	1	1	2	3	3	4	5	6	6
All others[a]	(see above)	1	2	3	4	5	6	7	8	9

[a] *All LF sub-levels are doubly degenerate (Kramer's doublets); this degeneracy can only be lifted in a magnetic field.*

For instance, Ce^{III} has only 2 spectroscopic levels, $^2F_{5/2}$ (ground state) and $^2F_{7/2}$ (excited state), and each split into a maximum of 3 and 4 sublevels, respectively, but Eu^{III} features 119 spectroscopic terms and 295 spectroscopic levels that in total can generate up to 3003 ligand-field sub-levels in a non-symmetric C_1 environment. Altogether the number of electronic levels for the Ce−Yb series is 16,384 for the $4f^n$ configurations and 180,199 for the $4f^{n-1}5\,d^1$ configurations. The two configurations only overlap substantially above 50,000 cm^{-1} ($\lambda < 200$ nm) (Fig. 11.3). This ladder-like structure of electronic levels makes lanthanide ions beautifully adequate for many photonic applications, including wavelength converting materials.

Finally, the ground spectroscopic SLJ level is readily determined using Hund's rules in sequence; it corresponds to:

Rule 1 The largest spin multiplicity.
Rule 2 The largest orbital multiplicity.
Rule 3 If $n < (2\ell + 1)$, $J = J_{min}$; if $n > (2\ell + 1)$, $J = J_{max}$; if $n = (2\ell + 1)$, $J = S$.

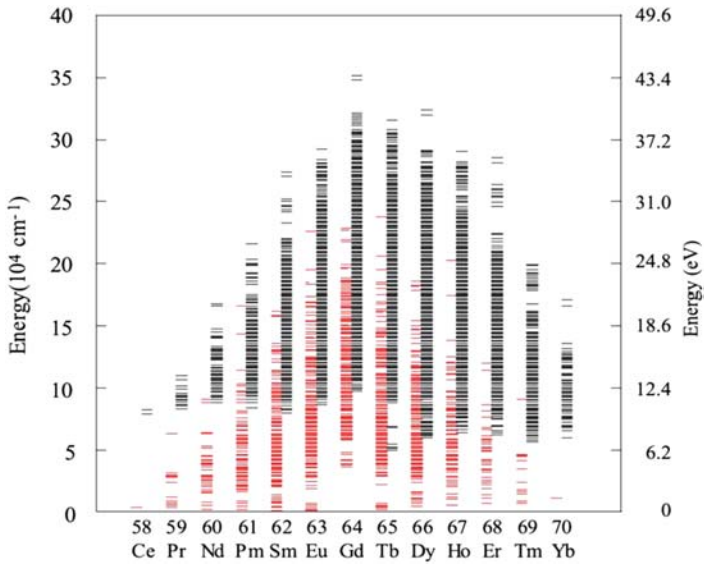

FIG. 11.3 Calculated energy diagram for all $4f^n$ (left, red [dark black in print version]) and $4f^{n-1}5\,d^1$ (right, black) electronic configurations of trivalent lanthanide ions. Ligand-field splitting is not taken into account. Note that for the right scale, 1 eV corresponds to 8066 cm^{-1}. *Adapted from Ogasawara, K., Watanabe, S., Toyoshima, H., Brik, M.G., 2007. First-principles calculations of 4f-4f5d transition spectra, in: Gschneidner Jr., K.A., Bünzli, J.C.G., and Pecharsky, V.K., Handbook on the Physics and Chemistry of Rare Earths, Elsevier Science B.V., Amsterdam, vol. 37, Ch. 231, pp.1−59.*

As examples, $Eu^{III}(4f^6)$ has ground state $^7F_0$ ($S = 3$, $L = 3$, $J = 0$) and $Tb^{III}(4f^8)^7$ has F_6 ($S = 3$, $L = 3$, $J = 6$), while Gd^{III} ground state corresponds to $^8S_{7/2}$. There is a relationship between the configurations $4f^n$ and $4f^{14-n}$ in that they have the same S and L quantum numbers, but the SO multiplet is regular for $4f^n$ with energy of the levels increasing with increasing J while it is inverted for $4f^{14-n}$ the energy of the levels increasing with decreasing J number.

11.2.2 Electronic transitions

Electronic transitions correspond to the rearrangement of electrons in the electronic configuration upon absorption or emission of light. Any rearrangement (i.e., transition) is not allowed. Transitions must obey *selection rules* that depend on the mechanism of absorption/emission. Since light is comprised of two perpendicularly oscillating electric and magnetic fields, each of them interact with corresponding dipoles in the electronic configuration leading to electric (ED) or magnetic (MD) dipole transitions.

The probability that a given transition occurs is defined by its *oscillator strength*. This is a positive dimensionless quantity ≤ 1 representing the ratio between the quantum mechanical transition rate and the classical absorption/emission rate of a single electron oscillating with the same frequency as the transition. Alternatively, the *dipole strength* can be used; for ED transitions, it is proportional to the square of the electric dipole and its unit is D^2cm^2 (D is the debye unit). Roughly speaking ED transitions are 10^2- to 10^3-fold more intense than MD transitions. More complex interactions such as quadrupolar ones also promote transitions, but their efficiency is much smaller ($\sim 10^4$ smaller than MD transitions) so that they are rarely observed or reported with an acceptable level of confidence.

11.2.2.1 Selection rules

Selection rules have been derived for pure electronic functions. In their hierarchy, the first one to be taken into account is the parity (or Laporte's) rule stating that an ED transition cannot occur between two levels of same parity. This obviously makes ED f-f transitions forbidden (similarly to ED d-d transitions). However, under the influence of the ligand field, of vibrations, and of the J-mixing, wave functions with opposite parity mix with the f-orbitals; therefore partially relaxing the selection rules derived for pure electronic functions. The corresponding transitions are called *forced ED transitions* (fED). Some of the fED transitions are particularly sensitive to minute changes in the Ln^{III} environment; they are labeled as *hypersensitive transitions* and are very useful to investigate changes in the coordination

sphere of the metal ion and/or in analytical chemistry. Anyhow, the oscillator strengths of the forced ED transitions remain small, with corresponding molar absorption coefficients not exceeding $12-15\ M^{-1}cm^{-1}$ (except for some hypersensitive transitions), and more usually in the range $0.1-1\ M^{-1}cm^{-1}$. On the other hand, MD f-f transitions are allowed by Laporte's rule; but they are quite weak. Depending on the symmetry, they can nonetheless have oscillator strengths on the same order of magnitude than forbidden ED transitions, so that both are commonly observed in f-f absorption and emission spectra. There are however few purely MD transitions, $Eu^{III}(^5D_0 \leftrightarrow {}^7F_1)$ being a typical example, and many transitions have a mixed ED/MD character making detailed interpretation of spectra sometimes difficult.

The second rule deals with the spin that should be kept constant during the transition ($\Delta S = 0$); it is valid for both ED and MD transitions. Other rules are concerned with changes in angular momentum (ΔL) and total momentum (ΔJ). Finally, the selection rules governing transitions between LF sublevels are more involved in that they depend on the symmetry around the emitting ion; they can be worked out using group-theoretical considerations. Selection rules are summarized in Table 11.2 along with the ground electronic configuration of the $4f^n$ ions and the numbers of electronic (^SL_J) levels and LF sublevels in C_1 symmetry.

Selection rules are the same for absorption and emission transitions.

11.2.2.2 Types of transitions

The following transitions can be observed in lanthanide-containing compounds. They are of vastly different intensities and often overlap with ligand-centered transitions.

- **Allowed interconfigurational $4f^n \leftrightarrow 4f^{n-1}5d^1$ transitions**

The promotion of a 4f electron into the 5d sub-shell is parity allowed. However the spin rule has to be taken into consideration so that only spin-allowed $4f^n \leftrightarrow 4f^{n-1}5\ d^1$ transitions have sizable intensity. The energy of these transitions depends largely on the metal environment since the 5d orbitals are external and interact directly with the ligand orbitals. As a consequence, they are also broader. The 4f-5d transitions have usually high energies (Fig. 11.4) so that only those of Ce^{III}, Pr^{III}, Sm^{II}, Eu^{II}, and Tb^{III} are commonly observed. It is noteworthy that in coordination compounds, they are often obscured by transitions involving ligands. The absorption spectrum of the $[Ce(H_2O)_9]^{3+}$ aqua ion is displayed in Fig. 11.5 along with the ligand-field splitting of both the $4f^1(^2F_{5/2}, {}^2F_{7/2})$ and $5\ d^1(^2D_{3/2}, {}^2D_{5/2})$ electronic configurations in D_{3h} symmetry. The absorption coefficients are of the order $10^2-10^3\ M^{-1}cm^{-1}$ owing to the allowed nature of the transitions both with respect

TABLE 11.2 (Left) Numbers of f-electrons (n), $^{S}L_J$ levels (N_{SLJ}), and ligand-field sublevels (N_{CF}) in C_1 symmetry, as well as ground electronic levels $^{(2S+1)}\Gamma_J$ for trivalent lanthanide ions; (right) selection rules for d-f and f-f transitions.

Ln^{III}	n	N_{SLJ}	$^{(2S+1)}\Gamma_J$	N_{CF}[a]	Main selection rules

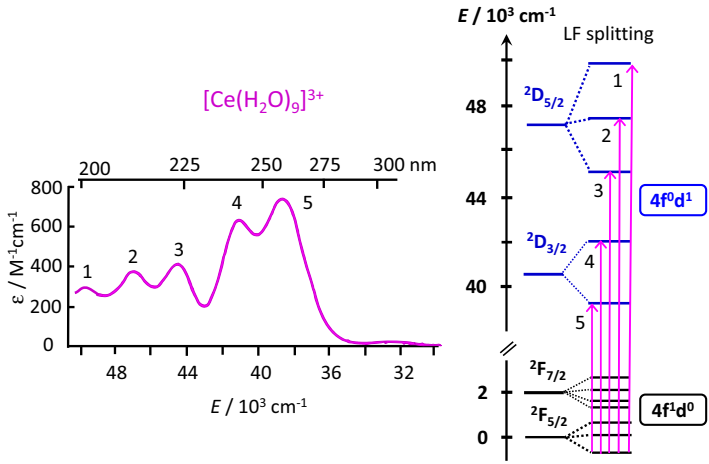

FIG. 11.5 Absorption spectrum of the Ce^{III} aqua ion with its interpretation in terms of $4f^1/5\,d^1$ electronic configurations. *Redrawn from Jørgensen, C.K., Brinen, J.S., 1963. Far UV absorption spectra of cerium(III) and europium(III) aqua ions. Mol. Phys. 6, 629–631.*

to Laporte's and spin rules. The ligand-field splittings of the $^2D_{3/2}$ and $^2D_{5/2}$ levels are approximately 3000 and 5500 cm^{-1}, respectively. Depending on the matrix or coordination compound into which Ce^{III} is inserted, its d-f emission can be tuned from about 290 to 500 nm because of large ligand-field effects on

the 5 d^1 excited configuration. The d-f emission of divalent lanthanide ions such as Eu^{II} or Sm^{II} can be even tuned into the red or the beginning of the near infrared and are useful in the design of light-emitting diodes (LEDs) (Qin et al., 2017).

- **Charge-transfer transitions**
  Charge transfer transitions are essential in sensitizing the luminescence of lanthanide-containing inorganic phosphors, but they can be totally detrimental in other instances, quenching light emission completely if the overlap with 4f-states is large (see Section 3.2). Three main types of charge transfer transitions may be present.
- **Ligand-to-metal charge transfers (LMCT):** During the process, an electron is transferred from the surrounding to the metal ion. As for the 4f-5d transitions, the corresponding energies are usually large, so that the transitions are often observed in the UV spectral range. The lowest energies occur for the easily reducible ions, namely Sm^{III}, Eu^{III}, Tm^{III}, and Yb^{III} as shown in Fig. 11.4 that displays calculated $2p(O) \rightarrow Ln$ transitions. Note that in this particular case, the transition is in principle forbidden since 2p and 4f orbitals have the same parity. The LMCT energies depend largely on the Ln^{III} surroundings and in complexes, covalent contributions to the bonding by organic ligands considerably lowers them, down to the range 18−25 000 cm^{-1} for Eu^{III}. In addition, the energy can be modulated by substitution at the coordinating ligands. Mixing of LMCT and 4f states leads to enhanced forced electric dipole f-f transitions. As an example, in the dinuclear complex with *p-t*-butyl-calix[8]arene H_8L, $[Eu_2(H_2L)(DMF)_5]$, such a state is located at 400 nm ($\varepsilon = 720\ M^{-1}cm^{-1}$) and the corresponding absorption band extends up to about 600 nm; as a consequence of the LMCT/4f-orbitals mixing, the very weak and highly forbidden $Eu^{III}(^5D_0 \leftarrow {}^7F_0)$ absorption band is enhanced by a factor ~5000, reaching $\varepsilon = 5\ M^{-1}cm^{-1}$, compared to $\varepsilon = 10^{-3}\ M^{-1}cm^{-1}$ for the aqua ion (Bünzli et al., 1993); this phenomenon is called *intensity stealing*.
- **Metal-to-ligand charge transfers (MLCT):** Commonly observed with d-transition metal ions, MLCT are very rarely identified in spectra of lanthanide complexes since +4 oxidation states are difficult to stabilize, except for Ce^{III}, which is easily oxidized into Ce^{IV}. The new chemistry of Pr^{IV} and Tb^{IV} that is presently developing might reveal more of these transitions (Rice et al., 2019; Gompa, 2020; Willauer et al., 2020).
- **Ligand-centered charge transfers:** If the ligand has polarized electronic distribution (e.g., in so-called push-pull ligands), then charge transfer can occur internally. The states are referred to as intraligand CTs (ILCTs) or intramolecular CTs (ICTs); sometimes more precision is added to point to the origin of the polarization, such as twisted intraligand CT (TICT). Such states are ideal for sensitizing lanthanide luminescence in view of their

large absorption and, often, of their relatively low energy; moreover substituent modification enables easy tuning of the ILCT energy.

In some heterometallic nd-4f polynuclear molecular edifices, singlet or triplet MLCT, LMCT, or MMCT (metal-to-metal CT) states linked to the d-transition metal may also act as convenient donors for transferring energy on the Ln excited states.

- **Intraconfigurational f↔f transitions**

Owing to the screening of the f-orbitals, these transitions are quite sharp with fwhh (full width at half height) usually in the range $0.1-30\ cm^{-1}$ only. Another consequence is their extremely small Stokes' shifts (energy difference between absorption and emission maxima), reaching only a few cm^{-1}. Their intensity is faint with oscillator strengths in the range of $10^{-4}-10^{-5}$ for spin-allowed fED transitions and $10^{-5}-10^{-6}$ for spin-allowed MD transitions. Spin-forbidden transitions are about 10−100 times less intense. Oscillator strengths of vibronic transitions, often associated with fED transitions, are in the range $10^{-7}-10^{-10}$ while those for electric quadrupole transitions are $\sim 10^{-10}$. As a comparison, the oscillator strengths of allowed f-d transitions range between 10^{-2} and almost 1.

Some characteristic features of f↔f transitions are exemplified in Fig. 11.6A and C along with an example of d-f emission spectrum for comparison (Fig. 11.6B). The tris(dipicolinate) complex $Cs_3[Eu(dpa)_3]$ in water has narrow absorption bands and small molar absorption coefficients ($<5\ M^{-1}cm^{-1}$), typical of an f-f spectrum. The emission spectrum of the neutral dinuclear helicate $[Eu_2L_3]$ in solid state at low temperature shows well resolved ligand-field splitting of the SLJ levels and points to how this splitting can be used to determine the symmetry of the coordination environment of the emitting ion; here, it is close to D_3 (refer to Table 11.1 for the number of expected components for each value of J) as indicated by the small splitting of the $^5D_0 \rightarrow {}^7F_1$ transition into two main components; since the E component is further split, this means that there is a deviation from D_3. Analysis of the transition to $^7F_2$ is more difficult because it contains some weak vibronic components. Note that the intensity of this fED transition is the same as that of the allowed MD transition to $^7F_1$. The d-f emission spectrum of the YAG:Ce^{III} (YAG is for yttrium aluminum garnet $Y_3Al_5O_{12}$) yellow phosphor is shown for comparison in (b); the broad band has fwhh $\sim$100 nm and features a maximum at 530 nm and a shoulder around 565 nm; referring to Fig. 11.5 (right), the labels of these two components would be $^2D_{3/2}$(lowest LF sublevel) $\rightarrow {}^2F_{5/2}$ and $^2F_{7/2}$, respectively.

11.2.2.3 Modeling the intensity of f-f transitions

Historically, the forbidden nature of lanthanide ED transitions made their intensity difficult to understand until 1953 when two researchers, Judd (1962)

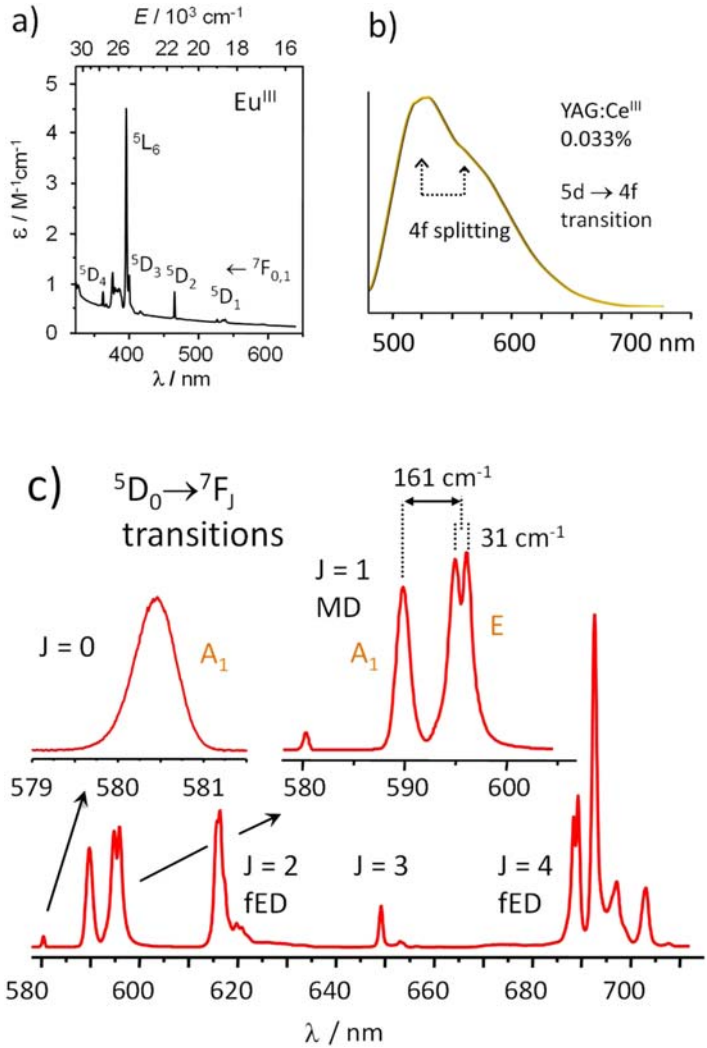

FIG. 11.6 (A) Absorption spectrum of $Cs_3[Eu(dpa)_3]$ 1.8×10^{-2} M in Tris-HCl 0.1 M (pH 7.4) at room temperature; refer to Fig. 11.2 (bottom) for the SLJ level labeling. (B) Emission spectrum of the yellow [light black in print version] phosphor used in first-generation LEDs, YAG:Ce^{III} (0.033%), in the solid state at room temperature. and Ofelt (1962), independently proposed the same theory, now known as Judd-Ofelt (JO) theory. The model has been established within the frame of the ligand-field concept and it provides a simple scheme for reproducing the intensities of f-f absorption spectra by use of three phenomenological parameters labeled Ω_2, Ω_4, and Ω_6. Spin-orbit coupling is treated by means of the intermediate coupling scheme but the model only takes into account the $4f^n$ electronic configuration, that is, inter-configurational $4f^n$-$4f^{n-1}5d^1$ interaction is neglected. It is further assumed that all LF sublevels within the ground level are equally populated, which is only true for non-degenerate electronic levels such as $Eu^{III}(^7F_0)$. Finally, the model is constructed for optically isotropic materials; it is therefore not valid for uniaxial or biaxial crystals, but, of course, holds for solutions. These hypotheses explain why sometimes JO theory does not perfectly reproduce the observed spectral intensities for some Ln^{III} ions. An outline is given below, but for more details, please refer to (Görller-Walrand and Binnemans, 1998; Bünzli, 2003; Walsh et al., 2006).

The dipole strength in esu^2cm^2 ($=10^{36}$ $debye^2$) of a fED f-f transition between an initial state $|\Psi_J\rangle$, characterized by a quantum number J, and a final state $|\Psi'_{J'}\rangle$ with quantum number J′is given by:

$$D_{ED} = e^2 \cdot \sum_{\lambda=2,4,6} \Omega_\lambda \cdot \left|\langle \Psi \| U^\lambda \| \Psi' \rangle\right|^2 \tag{11.2}$$

in which e is the electric charge of the electron, wavefunctions ψ and ψ' are full intermediate-coupled functions $f^n[SLJ]$, U^λ are components of the irreducible tensor of the ED operator, Ω_λ are the phenomenological Judd-Ofelt parameters, expressed in cm^2, and $\lambda = 2, 4, 6$. The bracketed expressions in Eq. (11.2) are dimensionless doubly-reduced matrix elements that are in principle insensitive to the metal-ion environment; they are tabulated.

JO parameters are adjustable and they are evaluated from the experimental dipole strength, in esu^2cm^2, calculated from the normalized absorption spectrum $\varepsilon\left(\widetilde{\nu}\right)$:

$$D_{exp} = \frac{10^{-36}}{108.9 \cdot \widetilde{\nu}_{mean} \cdot X_A} \cdot \left((2J+1) \cdot \frac{9n}{(n^2+2)^2}\right) \cdot \int \varepsilon\left(\widetilde{\nu}\right) d\widetilde{\nu} \tag{11.3}$$

with X_A being the fractional population of the initial state, $(2J + 1)$ is the degeneracy of the initial state and the expression involving the refractive index n is known as Lorentz's local-field correction while $\widetilde{\nu}_{mean}$, the barycentre of the transition, is given by:

$$\widetilde{\nu}_{mean} = \frac{\int \widetilde{\nu} \cdot \varepsilon\left(\widetilde{\nu}\right) d\widetilde{\nu}}{\int \varepsilon\left(\widetilde{\nu}\right) d\widetilde{\nu}} \tag{11.4}$$

It is worth noting that the oscillator strength is related to the dipole strength by the following equation:

$$P_{exp} = \frac{\widetilde{\nu}_{mean}}{2.127 \times 10^{-30}} D_{exp} = 4.32 \times 10^{-9} \cdot \int \varepsilon\left(\widetilde{\nu}\right) d\widetilde{\nu} \qquad (11.5)$$

The phenomenological JO parameters are determined from a fit of Eq. (11.2) to the experimental values defined by Eq. (11.3), using tabulated matrix elements. In the case of Eu^{III} the procedure is simpler since Ω_2, Ω_4, and Ω_6 can be directly extracted from the dipole strength of the $^5D_2 \leftarrow {}^7F_0$, $^5D_4 \leftarrow {}^7F_0$, and $^5L_6 \leftarrow {}^7F_0$ transitions, respectively. Indeed, all squared reduced matrix elements (Eq. 11.2) are zero for fED transitions originating from $^5D_0$ (or $^7F_0$) except for those involving the levels $^{(2S+1)}\Gamma_\lambda$ with $\lambda = 2, 4, 6$ and $\Gamma = D, F$ and for which the corresponding U^λ is non-zero. For instance, the parameters corresponding to the spectrum showed in Fig. 11.6A are $\Omega_2 = 10.3$, $\Omega_4 = 5.59$, and $\Omega_6 = 9.16$ in units of $10^{-20}\,cm^2$. The parameter Ω_2 is related to the polarizability (or covalency) of the Ln-ligand bonds. The JO parameters can also be calculated from excitation spectra, reflectance spectra and, for Sm^{III}, Eu^{III}, Tb^{III}, and Dy^{III} from emission spectra (Zhang et al., 2018). Extensive tabulations of JO parameters can be also found (Görller-Walrand and Binnemans, 1998).

An application, open-source, software for calculating the JO intensity parameters for Eu^{III} is now available under the name of JOES (Ciric et al., 2019). The program has a large database of refractive indices, which is crucial for calculating the spontaneous emission coefficient of the $Eu^{III}(^5D_0 \rightarrow {}^7F_1)$ MD transition used as internal reference for estimating the JO parameters.

11.2.2.4 Emission probability and radiative lifetime

The emission probability is given by Einstein's rates of spontaneous emission A (or k_{rad}) from an initial state $|\Psi_J\rangle$ to a final state $|\Psi\prime_{J\prime}\rangle$:

$$A(\Psi_J, \Psi\prime_{J\prime}) = k_{rad} = \frac{1}{\tau_{rad}} = \frac{64\pi^4\left(\widetilde{\nu}_{mean}\right)^3}{3h(2J+1)}\left[\frac{n(n^2+2)^2}{9} D_{ED} + n^3 D_{MD}\right] \qquad (11.6)$$

where τ_{rad} is the radiative lifetime of the emitting level, i.e., the lifetime in absence of non-radiative de-activation processes; h is Planck's constant (6.626×10^{-34}Js), D_{ED} is given by Eq. (11.2) and D_{MD} by Eq. (11.7), where c is the light velocity in vacuo and m_e the electron mass:

$$D_{MD} = \left(\frac{e \cdot h}{4 \cdot \pi \cdot m_e \cdot c}\right)^2 \cdot |\langle \Psi || L + 2S || \Psi\prime \rangle|^2 \qquad (11.7)$$

The radiative lifetime can therefore be extracted from the spectral intensity, that is from Eqs.(11.2), (11.6), and (11.7). Except in few cases, this calculation

is not trivial and large errors may occur, including those pertaining to the hypotheses made within Judd-Ofelt theory. Moreover, it is noteworthy that the local field correction is not the same for absorption and emission.

When the absorption spectrum corresponding to an emission spectrum is measurable, which may be the case when the luminescence transitions terminate onto the ground level, the radiative lifetime can be simply calculated from the following equation where N_A is Avogadro's number (6.023 … $\times 10^{23}$):

$$\frac{1}{\tau_{rad}} = 2303 \times \frac{8\pi c n^2 \tilde{\nu}^2 (2J+1)}{N_A (2J'+1)} \int \varepsilon\left(\tilde{\nu}\right) d\tilde{\nu} \tag{11.8}$$

In the special case of Eu^{III} for which one transition ($^5D_0 \rightarrow {}^7F_1$) has pure magnetic origin, a convenient, simplified equation can be derived (Werts et al., 2002), where $A_{MD,0}$ is the $^5D_0 \rightarrow {}^7F_1$ emission probability in vacuo and is equal to 14.65 s^{-1}, and I_{tot} and I_{MD} are integrated intensities of the entire emission spectrum and of the MD transition, respectively:

$$A(\Psi_J, \Psi\prime_{J\prime}) = \frac{1}{\tau_{rad}} = A_{MD,0} \cdot n^3 \left(\frac{I_{tot}}{I_{MD}}\right) \tag{11.9}$$

It is important to realize that the radiative lifetime depends on the refractive index, on the chemical environment of the emitting ion (bond polarizability), and on the specific emitting level. Another remark is that all the equations above are derived under specific hypotheses so that some deviations with experimental values may occur; on the other hand, it has been demonstrated that Eq. (11.8) yields a correct value of τ_{rad} is the case of Eu^{III} tris(dipicolinate) (Aebischer et al., 2009).

- **Vibronic transitions**

As indicated by their name, these transitions originate from mixing between 4f-orbitals and vibrational levels. They are mainly associated with fED transitions and have the same selection rules. Their intensity is about 10−100 times less than MD transitions and varies largely with temperature. This provides a mean of identifying them, which is crucial for not confusing them with LF transitions. Both Stokes and anti-Stokes vibronic transitions may be seen (Fig. 11.7).

11.2.3 Sensitization of lanthanide luminescence

The luminosity of a luminescent compound is characterized by its brightness B, the product of the molar absorption coefficient ε at the excitation wavelength by the quantum yield Q (Wong et al., 2020):

$$B = \varepsilon(\lambda_{exc}) \times Q \tag{11.10}$$

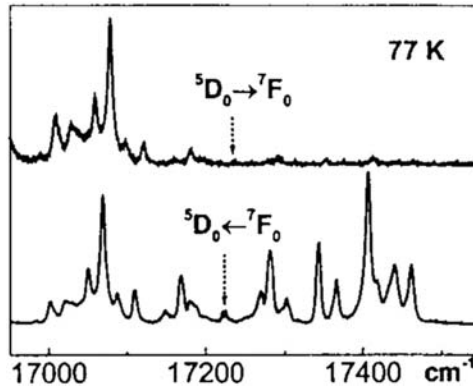

FIG. 11.7 Vibronic transitions associated with the $^5D_0 \rightarrow {}^7F_0$ and $^5D_0 \leftarrow {}^7F_0$ transitions in $NaCs_s[Eu(NO_2)_6]$ at 77 K. *Adapted from Bünzli, J.C.G., Petoud, S., Moret, E., 1999. Luminescent properties of the hexakis(nitrito)europate(III) ion, $[Eu(NO_2)_6]^{3-}$. Spectrosc. Lett. 32, 155–163. With permission.*

In the case of lanthanides, this brightness is seriously limited by the small molar absorption coefficients of f-f transitions. Fortunately, a major finding was made by Weissman (1942) who discovered that lanthanide luminescence can be triggered in molecular complexes by excitation into the ligand levels, followed by energy transfer onto the metal ion. Initial studies involved Eu^{III} β-diketonates, salicylates, phenolates, benzoates, and complexes with aldehydes. A mechanism for this *luminescence sensitization* (or *antenna effect*, Fig. 11.8) has been postulated in which the long-lived triplet state of the ligands is the principal donor state (Kleinerman, 1968). Its energy is not always easy to determine, especially if the ligand-to-Ln^{III} energy transfer is efficient. For this reason the 0-phonon component of the phosphorescent band of the Gd^{III} complex at low temperature (<77 K) is most often taken as the value to be considered. It was however soon recognized, based on the analysis of 600 Ln^{III} chelates, that the singlet state of the ligand may also play an important role in the energy transfer (Kleinerman, 1969), depending on the systems implied, particularly on the nature of the Ln^{III} ion, a fact now well established (Aquino et al., 2021).

In order to evaluate the efficiency of the sensitization process, one needs two quantum yields: Overall quantum yield Q_{ovl} obtained upon excitation into the ligand levels and the intrinsic quantum yield Q_{int} obtained by direct excitation into the f-f transitions. The sensitization efficiency is then given by (note that $Q_{int} \geq Q_{ovl}$, always!):

$$\eta_{sens} = \frac{Q_{ovl}}{Q_{int}} = Q_{ovl}\frac{\tau_{rad}}{\tau_{obs}} \tag{11.12}$$

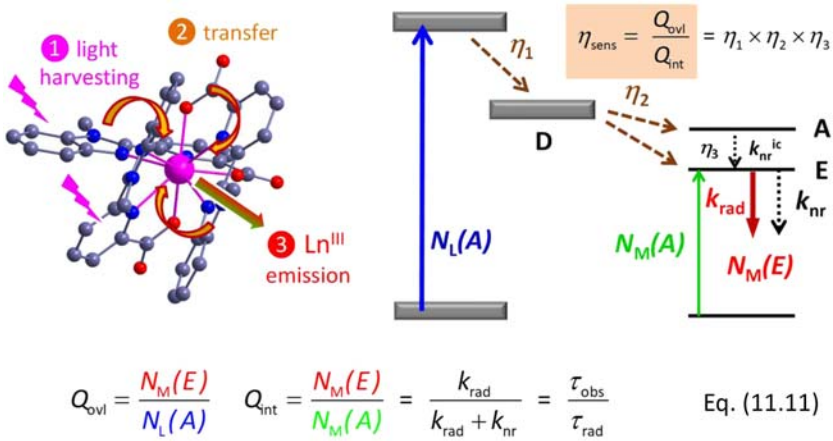

FIG. 11.8 (Left) lanthanide luminescence sensitization through the antenna effect: ① absorption by ligand, ② transfer onto Ln^{III}, and ③ Ln^{III} emission. (Right) simplistic modeling of the phenomenon: $N_X(A)$ are the numbers of photons absorbed by the ligand (X = L) or the metal ion (X = M) and $N_M(E)$ are the numbers of photons emitted; k_{rad} is the radiative rate constant, k_{nr} is the sum of non-radiative rate constants, k_{nr}^{ic} is the rate constant of internal conversion, η are efficiencies, D is the donor state, A the acceptor state and E the emissive state. Overall (Q_{ovl}) and intrinsic (Q_{int}) quantum yields are defined at the bottom (τ_{obs} is the observed lifetime of the emitting state).

An example of such an analysis is shown in Fig. 11.9 for 9-coordinate Eu^{III} complexes with pyridine-benzimidazole derivatives (Shavaleev et al., 2009a,b). The structure of all complexes has been determined by X-ray methods and the nature of their bonding analyzed by bond-valence theory. As expected from the similar coordination N_6O_3 environment, the radiative lifetime is rather constant over the series (3.9−4.6 ms) and so is the observed lifetime (∼2.5−3.0 ms), pointing to similar deactivation processes. With these data, the intrinsic quantum yield varies within narrow limits (0.53−0.67; note that uncertainty is of the order ±12%). The overall quantum yield shows somewhat larger variation (0.53−0.71, uncertainty ±10%). Except for complex 3, the sensitization efficiency is very large (0.82−1, uncertainty ±22%), pointing to very efficiency energy transfer. Therefore, if higher overall quantum yields would be needed, one would have to further minimize non-radiative deactivations. Finally, the brightness of the reported complexes is high: for complexes four to eight, for which Q_{ovl} has also be determined in CH_2Cl_2 solutions, molar absorption coefficients are in the range $5.1-6.0 \times 10^4\ M^{-1}cm^{-1}$ and Q_{ovl} are between 0.51 and 0.52, yielding brightness values in the range $2.7-3.1 \times 10^4\ M^{-1}cm^{-1}$.

11.2.4 Quantitative aspects of energy transfer processes

11.2.4.1 Simplistic model

As described above, the first mechanistic explanation of the antenna effect was the triplet pathway. Energy transfer depends on the orbital overlap between the donor (D) and acceptor (A) states, on the D-A distance and on the energy difference between the two states. In a simplistic, empirical approach scientists have tried to rationalize the quantum yields of Ln^{III} chelates (mainly Ln = Eu, Tb) by looking at the energy difference between the 0-phonon component of the triplet state, E^T_0, and the Ln^{III} emitting level. Although some correlations were obtained, one has to stress here that this can only be working, when comparing chelates with similar chemical environments or, rather, with chemical environments causing similar non-radiative deactivations. This is the case for the Eu^{III} tetrakis β-diketonates thoroughly studied by Sato and Wada (Fig. 11.10A). From this study, it can be concluded that an "ideal" energy gap would be around 2500 cm^{-1} for energy transfer on $Eu^{III}(^5D_0)$; they also

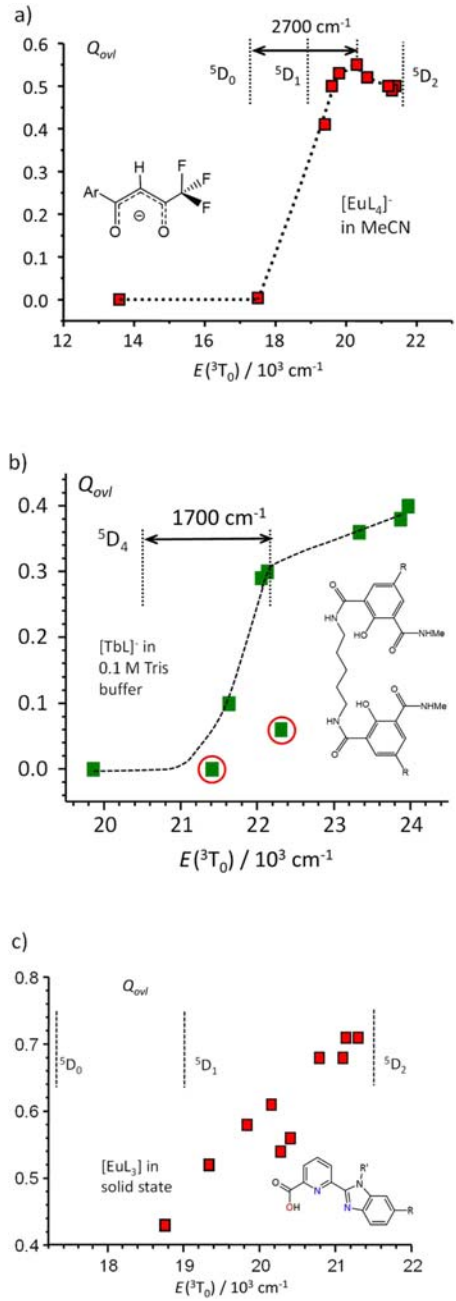

FIG. 11.10 Overall quantum yields versus the triplet state energy for (A) Eu^{III} tetrakis β-diketonates, (B) Tb^{III} chelates with 2-hydroxy-isophthalamides, and (C) Eu^{III} complexes with benzimidazole-pyridine derivatives. *Drawn from data based on Sato, S., Wada, M., 1970. Relations between intramolecular energy transfer efficiencies and triplet state energies in rare earths β-diketonates. Bull. Chem. Soc. Jpn. 43, 1955–1962; Shavaleev, N.M., Eliseeva, S.V., Scopelliti, R., Bünzli, J.C.G., 2009a. Designing simple tridentate ligands for highly luminescent europium complexes. Chem. Eur J. 15, 10790–10802; Shavaleev, N.M., Scopelliti, R., Gumy, F., Bunzli, J.C.G., 2009b. Surprisingly bright near-infrared luminescence and short radiative lifetimes of ytterbium in hetero-binuclear Yb-Na chelates. Inorg. Chem. 48, 7937–7946.*

established that a sizable portion of the excitation is funneled through the $^5D_1$ level, up to 99%, if $E^T{}_0$ becomes resonant with that level. Internal conversion then populates the $^5D_0$ level. Similar correlations have been worked out for Tb^{III} (Sato and Wada, 1970; Samuel et al., 2009) with about the same conclusion regarding the energy gap (Fig. 11.10B), i.e., quantum yields become larger than 30% when the energy gap is $>$ 1700-2000 cm^{-1}; however, two data points (red [dark black in print version]-circled) deviate from the correlation in Fig. 11.10B, probably because of the presence of ILCT in the ligands. For the compounds shown in Fig. 11.9, Q_{ovl} becomes >50% when the energy gap is >2000 cm^{-1} but then the quantum yield increases almost linearly with the energy of the triplet state (Fig. 11.10C). These examples point to the fragility of the energy gap rule especially that another point to consider is that charge-transfer states can relay energy when they are positioned between the singlet and triplet states (Puntus et al., 2008).

Moreover, when the coordination environment of the Ln^{III} ion is changing, the energy gap correlation does not work anymore: for instance, replacing one ligand by water molecules in a $[Ln(L_3)]$ complex to yield $[Ln(L_2)(H_2O)_3]$ will not influence the triplet energy of the ligand but the quantum yield will see a large decrease due to the quenching of Ln^{III} luminescence by the water molecules.

Accordingly, the energy gap rule should be used with great precaution and only considered as being a first simplistic approach. Not only does it fail to account for varying non-radiative deactivation processes but, equally importantly, it only considers one energy transfer path, one donor state, one acceptor state and, finally, it is rather silent on the exact mechanism considered while it is known that several mechanisms may potentially contribute to the transfer. In addition, the distinction between triplet, singlet, and charge transfer states is not always clear-cut as some of these states may mix.

11.2.4.2 Quantitative models and calculation packages

- **The LUMPAC program**

Quantum mechanical calculations are difficult to carry out for 4f-containing chelates. This may be the reason, why a workable model for the antenna effect had to wait the beginning of this century (de Sá et al., 2000). This model has been then constantly improved and an open-access software package designed for the Windows operating system (LUMPAC) (Dutra et al., 2014). The procedure has essentially been applied to Eu^{III} chelates, but it also works for other ions such as Sm^{III} (Gonçalves e Silva et al., 2002) and Tb^{III}. Many examples of such modeling have been published that are often in line with the triplet path of energy transfer but also point sometimes to the contribution of the singlet state and to the importance of the dipole-quadrupole mechanism. It is not the purpose of this chapter to give a detailed account of the model; however the readers are being directed to recent reviews (Neto et al.

2019a,b). The various steps of the LUMPAC procedure has been simply outlined and one example has been discussed. These steps are.

- Optimization of the ligand geometry using the Austin 1 procedure (AM1) or other more performing calculations like parametric models PM3, PM6, or PM7, all working within the frame of the Neglect of Differential Diatomic Overlap (NDDO) scheme.
- Optimization of the complex geometry using the Sparkle model within the Molecular Orbital Package (MOPAC) program, i.e., a central Coulomb potential with the Ln^{III} ion replaced with a +3e point charge and coupled with one of the AM1 or PMx procedures. Recent improvement uses the RM1 model for the Ln^{III} (Ln = Eu, Gd, Tb) ions: the {[Xe] $4f^n$} electronic configuration is described by the effective core potential with the RM1 core charge of the lanthanide set as $+3e$. The semi-empirical basis set used is composed of 5d, 6s, and 6p orbitals, for a total of 9 orbitals. With this model, Ln-X (X = C, N, O, S, Cl, Br) bond lengths can be predicted within ±0.06 Å (Dutra et al., 2014).
- Calculation of the ligand excited states and transition probabilities with Zerner's Intermediate Neglect of Differential Overlap (ZINDO) program.
- Calculation of the JO intensity parameters from the emission spectrum of Ln^{III} with the simple overlap model (SOM) for the odd-component of the ligand-field and the dynamic coupling mechanism for the contributions of ligand polarizability. Covalency effects are not considered explicitly and the calculation is limited to two parameters only, Ω_2 and Ω_4.
- Laying out a kinetic model of energy transfer taking into account the relevant ligand and Ln^{III} states (chosen by considering their respective energy and potential overlap), back transfer, as well as several mechanisms: Dipole-dipole (Förster), dipole-2^{λ}-multipole, and spin exchange (Dexter). Calculations have shown that dipole-quadrupole transfers may contribute substantially to the overall process, especially for ED forbidden transitions. Selection rules have also to be considered (Tanner et al., 2018): $|J - J'| < \lambda \leq |J + J'|$ for dipole-dipole and dipole-multipole transfer ($\lambda = 2$, 4, 6) and $|J - J'| = 0 \pm 1$ for exchange transfer; 0-0 transfers are excluded. These rules hold for pure orbitals and J-mixing can relax them, fortunately. In the case of Eu^{III}, direct excitation of $^5D_0$ from $^7F_0$ is forbidden by Laporte, ΔS, ΔL (however MD allowed), and ΔJ selection rules, but J-mixing, that can be estimated by the intensity ratio between $^5D_0 \rightarrow {}^7F_0$ and $^5D_0 \rightarrow {}^7F_2$ transitions effectively makes transfer to $^5D_0$ possible. Moreover, the $^5D_0 \leftarrow {}^7F_1$, $^5D_1 \leftarrow {}^7F_0$, and $^5D_1 \leftarrow {}^7F_1$ transitions are partially MD allowed (Table 11.3); the population of $^7F_1$ at room temperature is about 25%−30% so that this level is a important actor in the transfer process; it then rapidly relaxes to $^5D_0$.
- Solving the kinetic equations under steady state approximation and with Runge-Kutta method with adaptive integration steps. Finally, the quantum

$^5D_1 \leftarrow {}^7F_1$	X	√	X	X	X	X	X	√	√	√

yield can be determined from the calculated rate constants. Most of the calculated Q_{ovl} values are within ±10%−20% of the experimental data (themselves subject to an estimated similar experimental uncertainty (Ishida and Bünzli, 2016).

An example of such a calculation is shown in Fig. 11.11 for a dimeric Eu^{III} tetrakis(β-diketonate). The chosen model takes into account 3 levels for the ligand and 4 for the Eu^{III} ion. Internal conversion rate constants (10^6 s^{-1}) are estimated as well as fluorescence and phosphorescence rates of the ligand (based on experimental determinations for similar ligands). The calculated triplet state energy (20,030 cm^{-1}) is in good agreement with the experimentally determined one (21,320 cm^{-1}). The following conclusions can be drawn from the resulting rate constants: (i) Energy transfer from the singlet state contributes less than 0.01% to the total transfer, and therefore, the sample fit within the classical $S_0 \rightarrow S_1 \rightarrow T_1 \rightarrow {}^5D_{1,0}$ scheme; (ii) given the arguments developed above, it may be surprising that direct transfer to $^5D_0$ accounts for 56% of the overall transfer, overcoming transfer to $^5D_1$ (44%); this is partly due to much faster back transfer from $^5D_1$ (6.9×10^8 s^{-1}) compared with $^5D_0$ (1.8×10^5 s^{-1}) while the forward transfer rates are quite comparable; and (iii) Calculated quantum yield compares very well with the experimentally determined one, validating this semi-empirical procedure.

11.2.4.3 The JOYSpectra platform

In 2021, a free-of-charge web platform, termed JOYSpectra, has been proposed for online calculations of spectroscopic properties of lanthanide-based

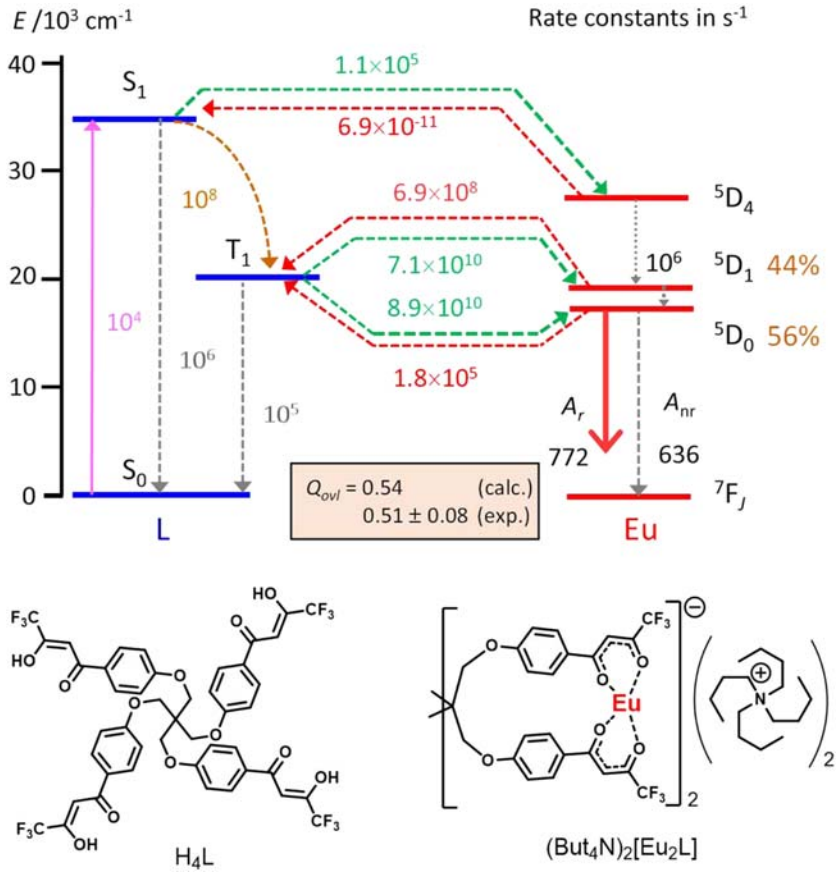

FIG. 11.11 Modeling of energy transfer processes in the Eu^{III} tetrakis(β-diketonate) dimeric complex $(But_4N)_2[Eu_2L]$ in solid state using the Sparkle/AM1 procedure (LUMPAC program). A_r and A_{nr} are the radiative and non-radiative rates, respectively. *Adapted from Biju, S., Freire, R.O., Eom, Y.K., Scopelliti, R., Bünzli, J.C.G., Kim, H.K., 2014. A Eu(III) tetrakis(β-diketonate) dimeric complex: photophysical properties, structural elucidation by sparkle/AM1 calculations, and doping into PMMA films and nanowires. Inorg. Chem. 53, 8407−8417. With Permission.*

compounds. It calculates and analyses the JO intensity parameters and evaluates intramolecular energy transfer rates from excited donor states up to 310 transitions involving 12 Ln^{III} ions (Moura et al., 2021). On the other hand, it does not calculate or optimize the geometry of the complexes that has consequently to be input, either under the form of Cartesian coordinates or as output of programs such as Gaussian, Orca, or MOPAC. The package is illustrated by convincing calculation of the energy transfers in and quantum yields for $[Ln(tta)_3(H_2O)_2]$ (tta is thenoyl-trifluoro-acetylacetonate; Ln = Eu, Tb).

11.3 Designing highly luminescent chelates (Bünzli, 2015)

11.3.1 Principles

The principles governing the design of highly luminescent lanthanide chelates are very simple to spell out: one has to maximize light absorption by the ligands, maximize energy transfer and minimize non-radiative de-activation processes. Additionally, one wants to try decreasing the radiative lifetime, in order to increase the intrinsic quantum yield, which can be done during the synthetic step by implementing polarizable Ln-ligand bonds or post-synthetically by incorporating the luminescent chelate into a matrix with large refractive index. In order to be successful, these optimizations can only be achieved taking into account the specific properties of each emitting ion and of their surroundings.

11.3.2 Optimizing energy transfer

This step is fairly well mastered for visible-emitting ions, particularly for Eu^{III} and Tb^{III}. In principle, ligands containing an extended aromatic π-system are favored since they feature relatively low-lying excited states. On one hand, one needs to elaborate a stable molecular construction with strong Ln-ligand bonds that are as polarizable as possible and make sure that the distance between the localisation of the electronic density of the donor orbital and the metal ion is as short as possible. There are basically two strategies. In the first one (Fig. 11.12, top), chromophores are appended to a spectroscopically silent chelate framework, here triazacyclononane is an example. Energy transfer from the chromophores induces Ln^{III} emission provided the aromatic system is positioned as close as possible from the metal ion and is orientated correctly. The overall quantum yield of the displayed Eu^{III} chelate amounts to 0.35 in water at pH 6.5 (Neil et al., 2014). Such a strategy favors dipole-dipole (Förster) energy transfer that has $1/r_{DA}^6$ distance dependence.

In the second strategy, the chromophore is incorporated into the ligand with the advantage of reducing the distance between the donor state and the Ln^{III} ion. Energy transfer through exchange (Dexter) mechanism is favored; since the distance dependence is in $e^{-r_{DA}}$, this mechanism is highly efficient for short distances, $r_{DA} < 5$ to 8 Å although in case of extended π-conjugation in the ligand, this can be expanded to about 20 Å (Lazarides et al., 2008). In the example depicted in Fig. 11.12 (bottom), the $Tb^{III}L_3$ complex exhibits a quantum yield of 0.66 in the solid state (Wartenberg et al., 2013).

The energy of the ligand donor state(s) should of course match reasonably well the Ln^{III} excited states, taking into account an adequate gap in order to minimize back energy transfer (see Section 11.2.4). Fig. 11.13 exemplifies the problem in the case the donor state is an MLCT state. The theoretical modeling is made for an initial $Q_{ovl} = 0.5$, for triplet and singlet state energies

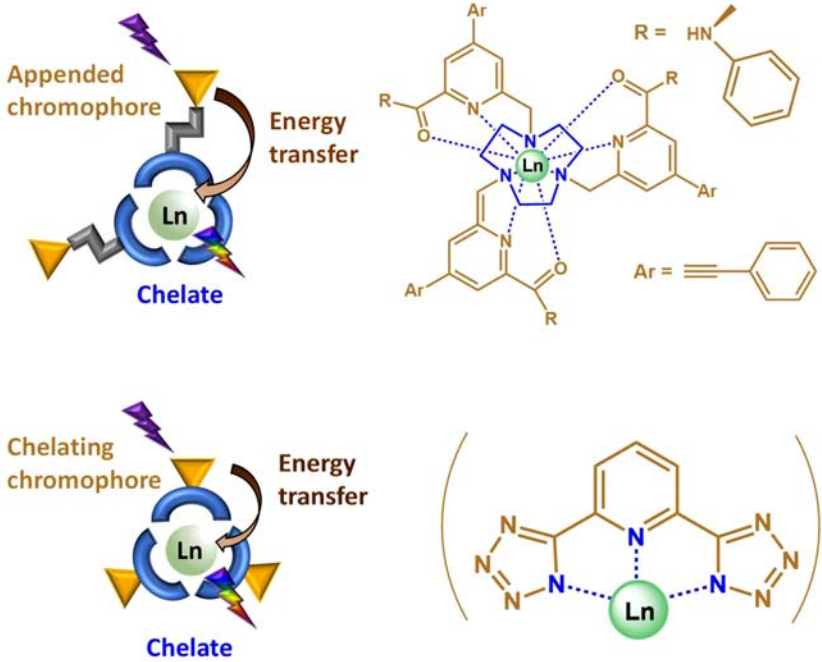

FIG. 11.12 Strategies for the synthesis of efficient antenna ligands. (Top) appended chromophore. FIG. 11.13 (Left) energy level scheme taken into account for modeling the influence of LMCT on the Eu^{III} quantum yield. (Right) results of the calculations for 3 values of the overlap integral between LMCT and ligand π orbitals: 0.01 (*solid line*), 0.05 (*dashed line*), and 0.10 (*dotted line*). *Adapted from Faustino, W.M., Malta, O.L., de Sá, G.F., 2005. Intramolecular energy transfer through charge transfer state in lanthanide compounds: a theoretical approach. J. Chem. Phys. 122, doi.10.1063/1.1830452. With Permission.*

set to 20,000 and 30,000 cm^{-1}, respectively, and it takes into account LMCT interactions with both 4f-orbitals and the $^1\pi$ and $^3\pi$ orbitals of the ligand. The magnitude of $Q_{ovl}(Eu^{III})$ is calculated for three values of the overlap between the LMCT and the π molecular orbitals, 0.01, 0.05, and 0.10. When the energy of the MLCT is between 8000 and 17,000 cm^{-1}, the quantum yield drops to almost nil. It then sharply increases up to 20,000 cm^{-1} and then decreases again up to the energy of the singlet state for finally regaining its initial value (Faustino et al., 2005). Experiments corroborating these variations are described in the literature, for instance for non-fluorinated and fluorinated β-diketonates (Zhuravlev et al., 2018).

11.3.3 Minimizing non-radiative deactivation processes

11.3.3.1 Photoelectron transfers (PET)

There are several non-radiative deactivation channels but the most important are temperature-dependent electronic and vibrational quenching. In the first one, termed *photo-induced electron transfer* (PET), an electron is transferred either from the ligand to the metal ion or from the metal ion to the ligand. The first alternative is more common and leads to switching the corresponding Ln^{III} luminescence off. This essentially happens for easily reduced ions. Many documented examples stem from Eu^{III} with the ligand reducing it to Eu^{II}; the condition for PET to occur is that the excited state energy of the ligand must be larger than the energy required for reducing the metal ion. Another way of looking into the competition between luminescence and PET is to consider the lowest oxidation potential for an antenna for which PET will not be possible for a given excited state. These redox potentials are plotted in Fig. 11.14 (top) for two excitation wavelengths, 280 and 330 nm. It is clear from this graph that PET is likely feasible for Eu^{III} and Yb^{III} for most organic ligands. Another, unexpected result is that even for ions like Sm^{III}, Tm^{III}, Dy^{III}, and, possibly, Nd^{III}, PET should be considered in the interpretation of their luminescence spectra. An example of the detrimental influence of PET process is shown in Fig. 11.14 (bottom). $[Eu(DPPOT)_3]^{3+}$ was found to have a very small quantum yield of 1% so that a detailed time-resolved photophysical study was undertaken to unravel its origin and it became evident that the culprit was the PET process that reduces Eu^{III} into Eu^{II}, switching off the trivalent ion luminescence (Ha-Thi et al., 2010).

The on/off (or off/on) switching of luminescence by PET is a convenient tool for analytical applications. Different analytical strategies take advantage of PET, including some in which the metal ion is not directly implied but its complexation modifies the energies of the excited states of the ligand with the consequence of, usually, switching the PET process off. For a comprehensive description, the reader is referred to the review by Kovacs and Borbas (2018). Regarding Yb^{III}, it is noteworthy that PET is involved in one mechanism proposed for sensitizing its luminescence by ligands having

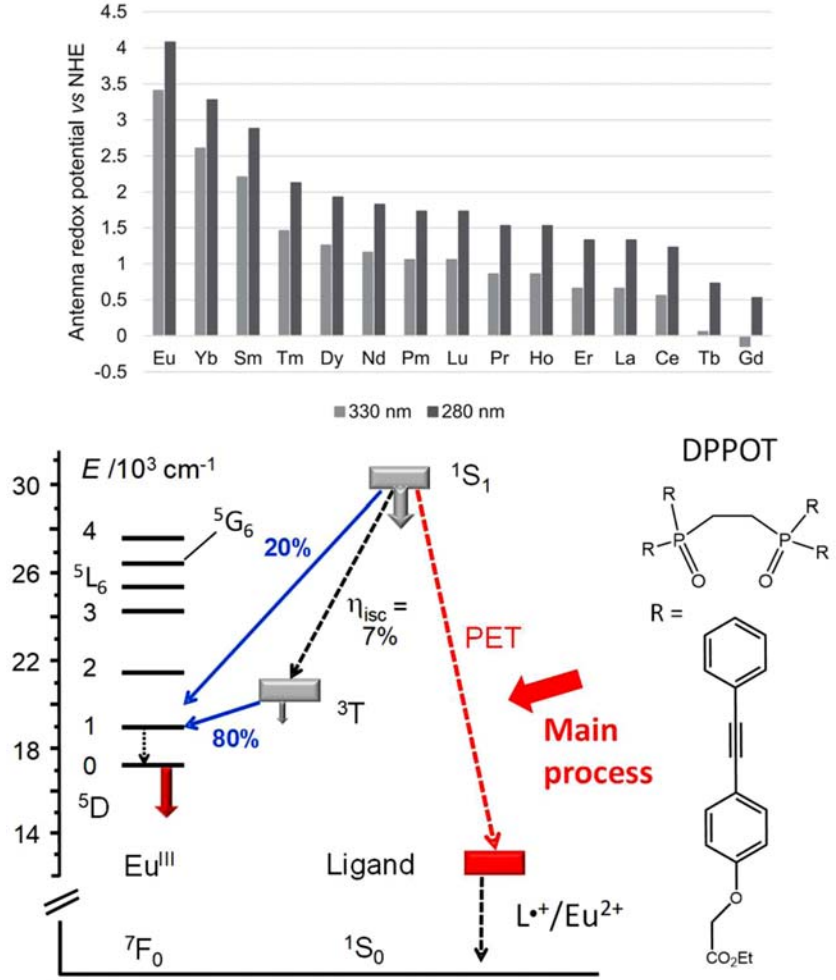

FIG. 11.14 (Top) antenna redox potentials below which PET to Ln^{III} ions is unfavorable for 280 and 330 nm excitation. (Bottom) Luminescence PET quenching of $Eu(NO_3)_3(DPPOT)_3$. *Adapted from Kovacs, D., Borbas, K.E., 2018. The role of photoinduced electron transfer in the quenching of sensitized europium emission. Coord. Chem. Rev. 364, doi.10.1016/j.ccr.2018.03.004. With Permission; Adapted from Ha-Thi, M.H., Delaire, J.A., Michelet, V., Leray, I., 2010. Sensitized emission of luminescent lanthanide complexes based on a phosphane oxide derivative. J. Phys. Chem., A 114, 3264−3269. With Permission.*

energetic excited states, that is when the energy gap is unreasonably large for efficient energy transfer to occur. In a first step, the ligand excited state transfers one electron onto $Yb^{III}(^2F_{7/2})$ reducing it to an excited divalent form $(Yb^{II})^*$; in a subsequent step, $(Yb^{II})^*$ transfers this electron back and

becomes excited $Yb^{III}(^2F_{5/2})$; then this species de-excites by emitting its characteristic NIR light at 980 nm.

11.3.3.2 Vibrational quenching

A major quenching channel is provided by vibrations in the surroundings of the emitting ion, a fact that has been recognized as early as the 1960s. For instance, Kropp and Windsor (1963) noticed that the luminescence intensity of lanthanide salts is enhanced in heavy water compared with regular water. They also pointed out that the enhancement is dependent on the energy gap between the emitting level and the highest-lying sub-level of the ground state, $\Delta E_{e\text{-}g}$. For instance, enhancement factors for chlorides were measured to be ~20, 8, and 1 for Eu^{III}, Tb^{III}, and Gd^{III}, respectively. That no enhancement was recorded for Gd^{III} was interpreted on the basis of its large gap, 32,100 cm^{-1} as compared with 14,800 and 12,300 cm^{-1} for Tb^{III} and Eu^{III}, respectively.

The rate constant for non-radiative deactivation by vibrations and their combinations/overtones depends on the energy of the vibration, $\hbar\omega$, the energy gap $\Delta E_{e\text{-}g}$, the distance between the oscillator and the emitting ion, and the temperature. The dependence with respect to the energies can be written as:

$$k_{nr} = C_1 \times e^{-C_2\left(\Delta E_{e-g}/\hbar\omega\right)} \tag{11.13}$$

in which C_1 and C_2 are empirically fitted parameters characteristic of a given system. The energy gaps for the luminescent Ln^{III} ions are reported in Fig. 11.15. The non-radiative deactivation will be more efficient if a small number of phonons are needed to bridge the gap. For instance, quenching $Tb^{III}(^5D_4)$ emission will require 4 O−H vibrations (or, more correctly, the fourth overtone of the O−H oscillator) while only about 3 are needed for de-activating $Eu^{III}(^5D_0)$, and therefore, the latter is more quenched than Tb^{III}. As a rule of thumb, an efficient luminescent molecular edifice should not have vibrations larger than 1/6th of the energy gap:

$$\hbar\omega_{max} < \frac{\Delta E_{e-g}}{6} \tag{11.14}$$

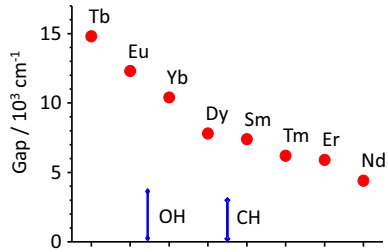

FIG. 11.15 Energy gaps $\Delta E_{e\text{-}g}$ in cm^{-1} for some lanthanide ions and energies of OH and CH vibrations.

This is relatively easy to realize for visible-emitting Ln^{III} ions in an inorganic environment, but much more difficult for NIR-emitting ions and for molecular complexes with organic ligands.

The simple "energy-gap law" treatment works well in many cases, particularly when considering Ln^{III} ions in solid inorganic matrices. It is however more problematic, when trying to interpret NIR luminescence of Ln^{III} molecular complexes. Indeed, it is based on several not always valid hypotheses: first, anharmonic and not harmonic oscillators should be considered, then the spectral overlap between the normalized emission spectrum $I_{em}\left(\widetilde{\nu}\right)$ and the vibrational spectrum $\varepsilon_{vib}\left(\widetilde{\nu}\right)$ plays an important role and should be incorporated into the model and, finally, several vibrations can be simultaneously active. Therefore, a more involved model was proposed, the *inductive-resonant mechanism* considering that the quenching is analogous to a dipole-dipole energy transfer with distance dependence in r^6. The non-radiative deactivation rate constant is then given by Eq. (11.15) (Doffek et al., 2012):

$$k_{nr} = \frac{161.9 \cdot k_r \cdot \kappa^2}{\pi^2 \cdot n^4 \cdot N_A \cdot r_{DA}^6} \times SOI \tag{11.15}$$

in which k_r is the rate of radiative deactivation in the absence of any non-radiative deactivation, κ is a factor depending on the relative orientation of the transition dipole moment of the donor (the Ln^{III} ion) and the acceptor (the quenching oscillator), n is the refractive index, N_A Avogadro's number and r_{DA} the distance between the Ln^{III} and the oscillator. Finally, the spectral overlap integral SOI is given by (Eq. 11.16)

$$SOI = \int I_{em}\left(\widetilde{\nu}\right) \cdot \varepsilon_{vib}\left(\widetilde{\nu}\right) \cdot \widetilde{\nu}^{-4} d\widetilde{\nu} \tag{11.16}$$

This model could explain quantitatively, why deuteration of a Pr^{III} cryptate leads to less emission intensity from the $^1D_2$ level whereas the contrary was expected. The reason is that the third harmonic of the C-D vibration overlaps better with the $^1D_2 \rightarrow {}^1G_4$ transition than the second harmonic of the C−H vibration, resulting in a larger SOI, as shown in Fig. 11.16.

11.3.3.3 Winning strategies for avoiding vibrational quenching in NIR emission (Hernandez and Gillin, 2015)

As can be inferred from the previous section, deuteration of the ligands and, when appropriate, of the solvent, will, in general, considerably minimize vibrational quenching. Deuteration of ligands or complexes can be simply achieved by exchange reaction with deuterated solvents and is therefore easy to achieve. When a complex contains coordinated water molecules that are replaced with D_2O, the effect is usually large for an ion such as Eu^{III} and

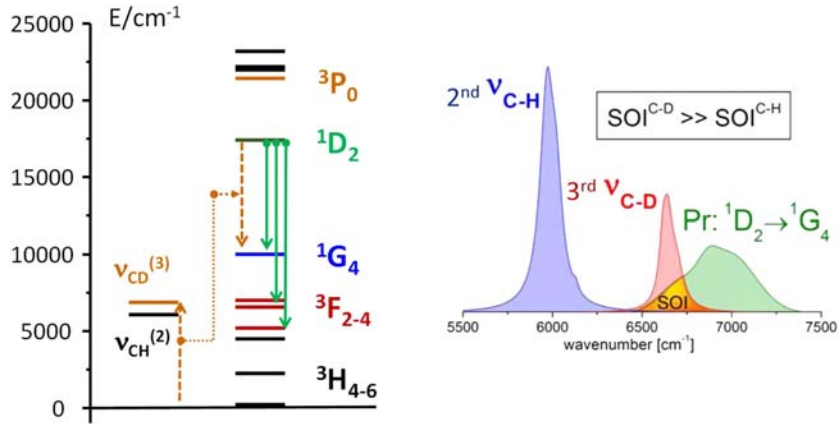

FIG. 11.16 (Left) energy diagram for the Pr^{III} cryptate with (bpy.bpy.bpy) showing quenching of $^1D_2$ by the third harmonic of the C-D vibration. (Right) spectral overlap integrals of the second C−H harmonic and third C-D harmonic. *Adapted from Doffek, C., Alzakhem, N., Bischof, C., Wahsner, J., Güden-Silber, T., Lügger, J., Platas-Iglesias, C., Seitz, M., 2012. Understanding the quenching effects of aromatic C−H- and C−D-oscillators in near-IR lanthanoid luminescence. J. Am. Chem. Soc. 134 16413−16423. With permisson.*

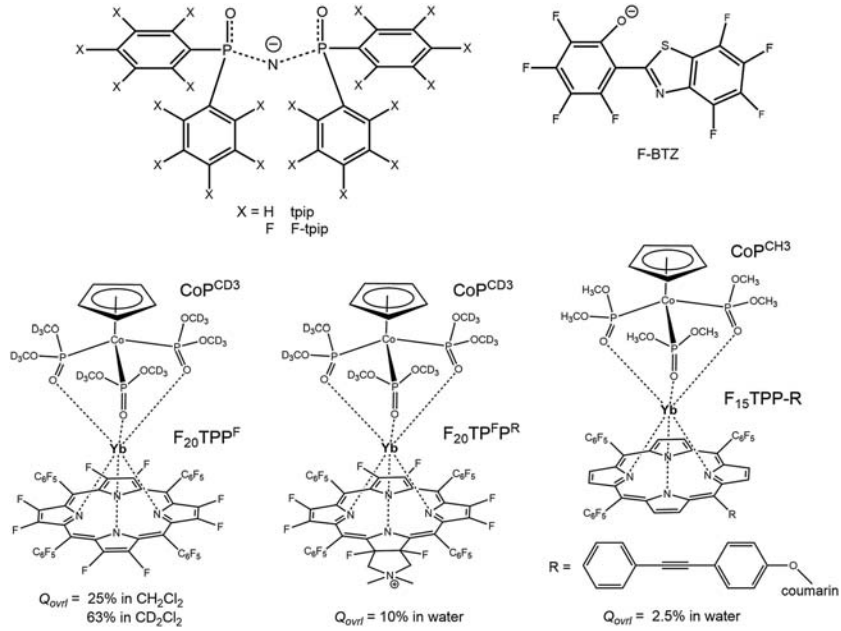
moderate for Tb^{III}. However for NIR-emitting ions such as Nd^{III}, Er^{III}, or Yb^{III}, this may not be always sufficient. For instance, after deuteration of [Nd(hfa)$(H_2O)_2$] to yield [Nd(hfa-D)$_3$(D_2O)$_2$], where hfa^- is hexafluoroacetylacetonate, vibrational non-radiative deactivations remain important and the overall quantum yield is still very low, e.g., 0.004 in acetone-d_6; replacement of the D_2O molecules with DMSO-d_6 increases Q_{ovl} about 3-fold, but its value is still uninterestingly small, at 0.011 (Hasegawa et al., 1996). Not only are O−H vibrations heavily quenching NIR luminescence but, also, N−H and C−H vibrations, ubiquitous in organic ligands. It has been calculated that in Cs[Er(hfa)$_4$], the rate constant for luminescence deactivation by one C−H vibration, k_{CH}, is equal to 91 ms^{-1} so that a single C−H oscillator located at 20 Å of an emitting Er^{III} ion quenches half its emission! A summary of some k_{XH} rate constants is given in Table 11.4.



Another strategy has been proposed: halogenation instead of deuteration, or, sometimes, a combination of both. One advantage of halogenation, more particularly chlorination and bromination is the heavy atom effect of the halogen that, in addition to minimizing vibrational quenching, promotes triplet population via intersystem crossing. Despite this, fluorination remains the most common way of switching off non-radiative deactivations in molecular NIR-emitting complexes (Hernandez, 2015). It has several effects due to the strong withdrawing properties of the fluorine atoms. This makes more difficult for the ligand to bind the metal ions but, on the other hand, it also allows more orbital mixing with concomitant reduction of the radiative lifetime, and hence,

TABLE 11.4 Selected rate constants for the quenching of Nd^{III}, Er^{III}, and Yb^{III} luminescence by C−H and C-D oscillators.

Complex	Oscillator	Distance/Å	k_{CX}/ms^{-1}
$Cs[Nd(hfa)_4$	C−H	4.7	600

increasing the emission efficiency (Ye et al., 2013). Another drawback of some fluorinated ligands, even if they present reasonable complexing properties and enhancement of f-f oscillator strengths, is their insufficient antenna effect or the fact that they have to be excited in the UV. For instance, the ligand tpip (Scheme 11.1) yields [Ln(tpip)$_3$] complexes with lifetimes of 2.7 (Nd^{III}), 6.5 (Er^{III}), and 53 (Yb^{III}) µs in dry MeCN (Bassett et al., 2005). Fluorinating the ligand results in lengthening these lifetimes to 46, 316, and 582 µs in solid state, respectively (Glover et al., 2007). The corresponding intrinsic quantum yields for the Er^{III} complexes calculated with $\tau_{rad} = 8$ ms, are 0.05% and 1.8% in solid state (Mancino et al., 2005). The problem is the excitation wavelength of 266 nm. To overcome this drawback, an interesting strategy has been proposed by Ye et al. (2014): Introduction of an additional chromophore separated from the chemical environment of the emitting Ln^{III} ion, $[Zn(F\text{-}TBZ)_2]_2$, that can be excited at 368 nm. A waveguide has been fabricated comprising a 2-µm film of $[Zn(F\text{-}TBZ)_2]_2$ doped at 30% [Er(F-tpip)$_3$] and deposited onto a 0.7-µm SiO_2 layer on a silicon substrate. Amplification performances are good and the device can easily be integrated with other components.

SCHEME 11.1 Chemical formulae of tpip, F-tpip, and of the Yb^{III} monoporphyrinates with large quantum yield.

Another successful move was to replace oxygen with sulfur in $[Ln(XC_6F_5)_3(DME)_2]$ (Ln = Nd, Er, Tm), where DME is 1,2-dimethoxyethane and $(XC_6F_5)^-$ pentafluoro phenolate (X = O) or perfluoro benzenethiolate (X = S). The luminescence efficiency, calculated from the lifetimes (i.e., corresponding to Q_{int}) increases from 2% to 9% for Nd^{III} and from 19% to 75% for Er^{III}; the effect is far less pronounced for Tm^{III} for which the efficiency of the $^3H_4 \rightarrow {}^3F_4$ emission remains almost constant (from 1.9% to 2.0%) (Norton et al., 2009).

A remarkable improvement in the quantum yield of Yb^{III} complexes has recently been achieved. Despite a relatively large $^2F_{5/2}$-$^2F_{7/2}$ energy gap of $\sim$10,500 cm^{-1}, quantum yields of Yb^{III} chelates were long confined in the range 1%–4% (Shavaleev et al., 2009a,b). Well in line with this statement, the Yb^{III} tetrakis(pentafluorophenyl)porphyrinate capped with Kläui's ligand, [Yb(F_{20}TPP) (CoP^{CH3})], has an overall quantum yield of 2.4% in methylene chloride (Hu et al., 2017), an already large improvement over the non-fluorinated complex that presents no Yb^{III} emission. Fluorinating the β-positions of the macrocycle increases the quantum yield to 5.1% for [Yb($F_{20}TPP^F$) (CoP^{CH3})]. Further drastic improvement comes from the deuteration of Kläui's ligand with the quantum yield reaching 25% for [Yb($F_{20}TPP^F$) (CoP^{CD3})]

(Scheme 11.1) in CH_2Cl_2 and 63% in CD_2Cl_2 while the lifetime increases from 49 to 285 μs in CH_2Cl_2 and from 54 to 714 μs in CD_2Cl_2. The influence of the β-substituents is also quite dramatic and can be deciphered by comparing the overall quantum yields for [Yb($F_{20}TPP^X$) (CoP^{CD3})] which increase from 3.9% (X = H) to 15% (X = D) and 25% (X = F), respectively. On the other hand, the hydrogen atoms of the phenyl substituents have less effect, the overall quantum yield of [Yb(TPP^F) (CoP^{CD3})] remaining high at 20%, with a lifetime at 197 μs. Therefore, combined complete fluorination of the macrocycle and partial deuteration of the tripodal ligand improves the quantum yield by one order of magnitude! Interestingly, the ligand can be modified for rendering the complex water-soluble by fusing a dimethylpyrrolidinium group into it: the quantum yield of [Yb($F_{20}TP^FP^R$) (CoP^{CD3})] amounts to 10% in water and 23% in DMSO (Ning et al., 2018), representing a large improvement with respect to the best Q_{ovl} obtained so far in water for an Yb^{III} monoporphyrinate with F_{15}TPP-R linked to coumarin (Scheme 11.1), 2.5% (Zhang et al., 2011).

11.3.4 Examples of efficient sensitizing systems

The design of highly luminescent compounds must meet several requirements, which may be different depending on the emission spectral range and on the end use of the material. Brightness is of course a crucial parameter and molecular designers will attempt to optimize both η_{sens} and Q_{int} as described above by finding the antenna most suitable for the targeted Ln^{III} ion and by tailoring a rigid coordination environment, devoid of high-energy vibrations as much as possible. In addition, dedicated needs are required for specific applications. For instance, luminescent materials for light-emitting diodes, solar energy conversion, telecommunications, or luminescent coatings should display high thermal stability and easy processing, while luminescent bioprobes should be thermodynamically stable and kinetically inert in live biological environment and, at the same time, they should be non-cytotoxic. Finally, solubility may also be an important issue. The subject is vast and out of the scope of this chapter so that in the following, only a few examples of efficient antenna chromophores for selected Ln^{III} ions are given to help the reader figuring out where the field stands presently (Table 11.5, Scheme 11.2). Data reported in Table 11.4 are overall quantum yields only. In the literature intrinsic quantum yields derived either from lifetime measurements, or measured by direct f-f excitation are often reported, as well as partial quantum yields, especially for NIR-emitting ions. It is noteworthy that for a given compound, the quantum yield is often smaller in solution compared to solid state, unless unwanted interactions (e.g., excimer formation, or concentration quenching) occur in this state.

As one can gather from the data listed in Table 11.4, presently, quantum yields between 80 and almost 100% are common for Eu^{III} and Tb^{III} chelates.

TABLE 11.5 Quantum yield data for selected Ln^{III} coordination compounds. Ligand formulae are given in Scheme 11.2.

SCHEME 11.2 Formulae of the ligands and complexes mentioned in Table 11.4. Ln labels refer to the lanthanides coordinated by the displayed ligand.

This figure decreases to about 10%−25% for Dy^{III} and Yb^{III} complexes in the solid state or in non-deuterated solvents. With deuterated solvents, Q_{ovl} of Yb^{III} porphyrinates and porpholactonates can be much higher, in the range 50%−60%. Until now no Sm^{III} complex has been reported with Q_{ovl} much larger than 10%. Pr^{III} and Nd^{III} chelates have quantum yields of 1%−2% only and Tm^{III} chelates have difficulty in reaching 1%. This is apparently also true for Er^{III}, except for the systems developed for telecommunications mentioned above and for which long lifetimes have been reported (Peng et al., 2017), foreshadowing quantum yields of a few percent.

Considering the amazing advances made during the past decade, particularly for Yb^{III} complexes, one may be reasonably optimistic that in near future, similar efforts will contribute to considerably better the emissive properties of the complexes with, presently, poorly emitting Ln^{III} ions. However, each Ln^{III} ion will preferably have to be considered for its own properties. Indeed, literature survey shows that there are few ligands able to sensitize several different lanthanide ions or when they do, the sensitization is efficient only for a few of them (Zhang and Petoud, 2008; Salerno et al., 2020).

11.4 Luminescent lanthanide chelates at work

Luminescent lanthanide chelates are at the heart of numerous applications (Bünzli and Eliseeva, 2013), particularly in the field of biology and medicine (Bünzli, 2014). Here only a flavor of them is given with three noteworthy applications.

Circularly polarized luminescence (CPL) occurs, when a luminophore is chiral. Since in nature most biological molecules are chiral, CPL is an extremely valuable tool for exploring their primary and secondary structures. Among CPL luminophores, it happens that chiral lanthanide complexes present a high dissymmetry factor g_{lum} (particularly when emission arises from the $Eu^{III}(^5D_0 \rightarrow {}^7F_1)$ transition):

$$g_{lum} = 2\frac{(I_L - I_R)}{(I_L + I_R)} \tag{11.17}$$

where I is equal to the emitted light intensity and L and R represent left and right, respectively. For instance, Frawley et al. (2016) have recently demonstrated that triazacyclononane complexes $[EuL^1]$ and $[EuL^2]$ (Fig. 11.16, top) can be used for time-gated contrast imaging. The complexes have reasonably large Q_{ovl}, around 50%, and τ_{obs} around 1.2 ms enables easy time-resolved (TR) experiments. Dissymmetry factors for $[EuL^2]$ are between +0.15 and −0.32, depending on the transition. A commercial time-resolved epifluorescence microscope has been modified in order to separate left- and right-handed luminescence emitted by enantiopure Λ- and Δ-[EuL] by means of a quarter-wave plate and a linear polarizer; the right channel detects right

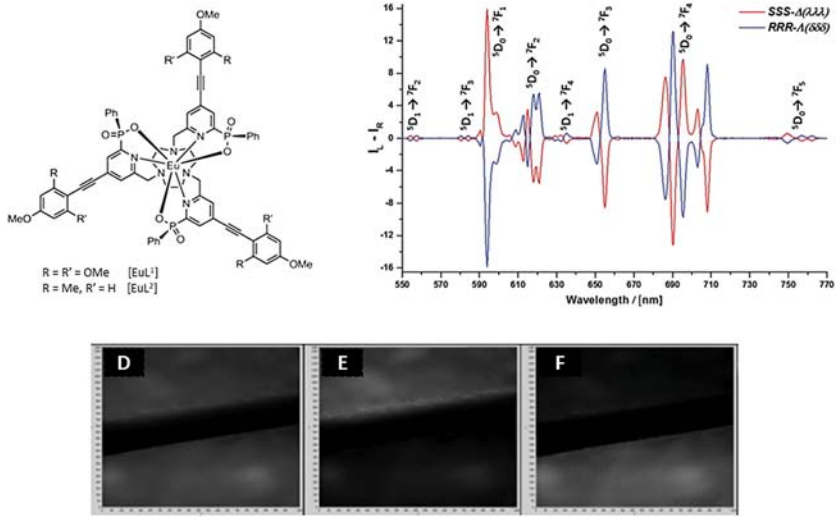

FIG. 11.17 (Top) formulae of Eu^{III} complexes, whose chiral enantiomers display CPL; the CPL spectra of Δ- and Λ-[EuL^2] are displayed on the right. (Bottom) time resolved images of (top) Λ-[EuL^2] and (bottom) Δ-[EuL^2]: D without chiro-optical selection, E right circularly polarized channel, F left circularly polarized channel. *Adapted from Frawley, A.T., Pal, R., Parker, D., 2016. Very bright, enantiopure europium(III) complexes allow time-gated chiral contrast imaging. Chem. Commun. 52, 13349–13352.*

circularly polarised light and the left channel left circularly polarized light. The obtained contrast is evident from Fig. 11.17 (bottom) that could easily be taken advantage of in biosciences and, also, in security tagging.

Creatine kinase (CK) is an important cardiac biomarker that is often used in the clinical diagnosis of acute myocardial infarction. It is therefore desirable to have an efficient assay enabling its quantification at ultralow levels. A bioassay relying on an Eu^{III} metal-organic framework (MOF) with $Q_{ovl} = 48\%$ meets this requirement with CK activity detected down to about 1 U/L (Li et al., 2019). Nanoparticles (NPs) of the corresponding MOF were synthesized from 1,1′:4′,1″:4″,1‴-quaterphenyl-3,3‴,5,5‴-tetracarboxylic acid (H_4QPTCA), europium acetate and oleic acid. When adenosine triphosphate (ATP) is added to a solution of $[Eu(QPTCA)]_\infty$ its intense red emission is quenched, probably because of a PET from ATP to the ligand. On the other hand, adenosine diphosphate (ADP) has a less important quenching effect. This observation and the fact that CK catalyzes the transformation of ATP into ADP while simultaneously converting creatine (Cr) into phosphocreatine (CrP) are the basis of the bioassay described in Fig. 11.18. The analytical reagent is prepared by mixing Eu-QPTCA NPs with creatine and ATP in a solution buffered at pH 9.0. The assay is conducted on human serum samples deposited in a 96-well microplate to which the reagent is added. The Eu^{III}

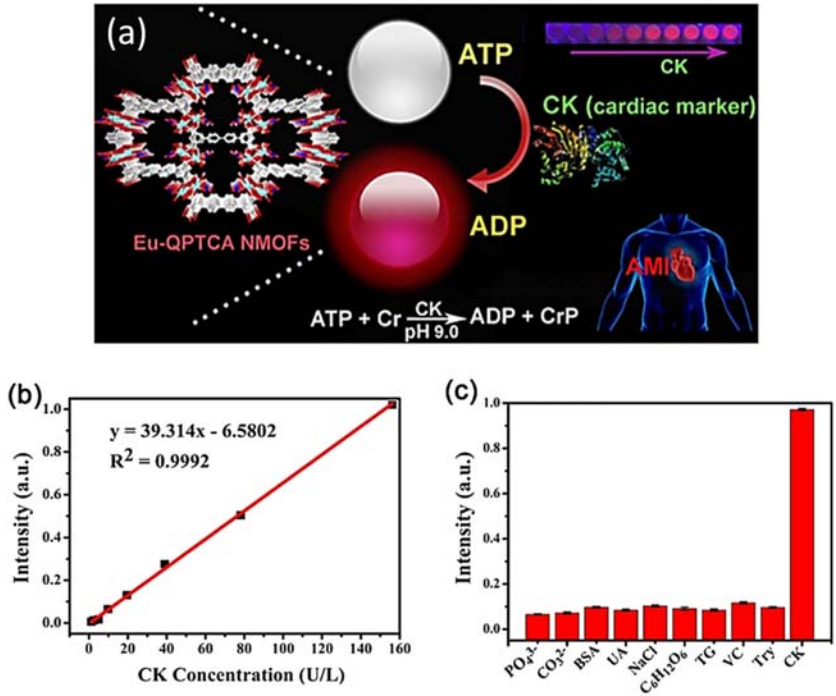

FIG. 11.18 (A) Principle of a bioassay based on an Eu^{III} MOF with $QPTCA^{4-}$. (B) Linear relationship between Eu^{III} emission intensity and the concentration of creatine kinase. (C) Selectivity of the assay with respect to several other analytes. *Adapted from Li, X., Zhou, S., Lu, S., Tu, D., Zheng, W., Liu, Y., et al., 2019. Lanthanide metal-organic framework nanoprobes for the in vitro detection of cardiac disease markers. ACS Appl. Mater. Interf. 11, 43989–43995.*

luminescence is detected in TR mode (delay 0.2 ms) after suitable incubation time. The linear range of the assay is between 1.2 and 156 U/L. The validity of the assay was tested on 100 human serum samples for which CK concentrations between about 40 and 165 U/L were determined by both; the present assay and conventional one; the correlation is very good, with an R^2-factor equal to 0.98.

The Epstein–Barr virus (EBV) belongs to the γ herpes virus family. It infects about 90% of the world population causing latent infection in most cases. The virus replicates in oral epithelium but infects B lymphocytes; it persists in the memory B-cell pool and the host remains asymptomatic with a life-long latent infection. EBV is associated with several distinct human tumors, Burkitt's lymphoma, Hodgkin's disease, B-cell lymphoproliferative syndromes, plasmablastic lymphoma and primary effusion lymphoma. EBV is also linked to non B-cell tumors including T/NK cell lymphomas, nasopharyngeal, and gastric carcinomas; furthermore, it is the causal agent for infectious mononucleosis.

During a latent infection, only a few EBV genes are expressed; latent membrane protein 1 (LMP1) is one of these genes and is the major transforming protein of EBV. With its localization in the cell membrane, LMP1 emerges as an attractive therapeutic agent in EBV-associated malignancies. LMP1 contains a cytoplasmic N-terminus, six trans-membrane domains labeled TM1-6, and a cytoplasmic C-terminus. It works by mimicking the cell surface receptor CD40 to prevent apoptosis of infected B-lymphocytes and drive their proliferation. Several cellular signaling pathways are activated, including those of the nuclear factor NF-κB. The Tm domain TM1 is critical for clustering the LMP1 monomers and therefore, activating them. In particular, the amino acid sequence $FWLY_{38\text{-}41}$ of TM1 plays an essential role in NF-κB activation.

Therefore, the peptide P19 (Pra-KAhx-K-LDLALK-FWLY-K-IVMSDKW-K-RrRK) was designed to mimic the key amino acid sequence $FWLY_{38\text{-}41}$ and for inactivating the NF-κB signal transduction (Chau et al., 2021). This peptide was appended onto lanthanide probes based on a derivatised macrocyclic dota receptor (Fig. 11.19). The EuP19 and YbP19 probes are

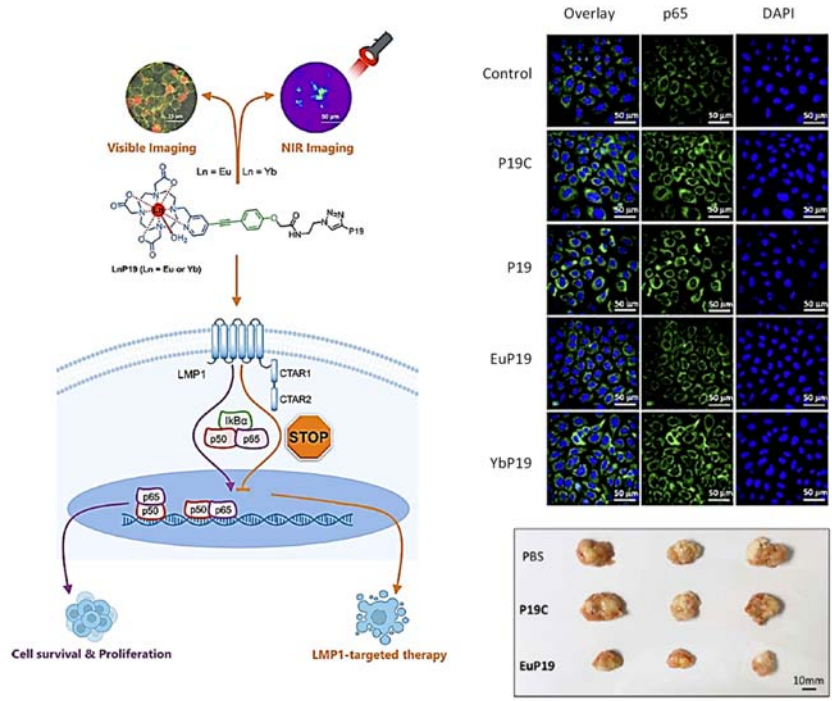

FIG. 11.19 (Left) principle of cancerous cell proliferation inhibition imaging by the LnP19 probes (Ln = Eu, Yb), (Right) imaging ability of the probes (HeLa cells) and tumor inhibition in three groups of LCL3-xenograft mice. *Adapted from Chau, H.F., Wu, Y., Fok, W.Y., Thor, W., Cho, W.C.S., Ma, P.A., et al., 2021. Lanthanide-based peptide-directed visible/near-infrared imaging and inhibition of LMP1. JACS Au, 1, doi 10.1021/jacsau.1c00187. With permission.*

designed for visible and NIR imaging, respectively, while both interact with the TM1 region of LMP1 and inhibit cancer growth. A modified peptide interacting with TM2, and therefore unable to interrupt the oligomerization of LMP1 was also synthesized as control. The in vitro imaging capability of the LnP19 probes are shown for HeLa cells and their prevention of tumor growth on xenograft mice is exemplified in Fig. 11.18. These probes exhibit high cytotoxicity toward LMP1-expressing cells and will contribute to therapeutic advances in Epstein−Barr related cancers.

11.5 Conclusion

This short overview on the luminescence of lanthanide coordination compounds points to its importance in several high-technology applications, particularly in the field of biomedicine. The design of such compounds is intricate and we have tried to draw the attention of the reader on several aspects that are not always reported correctly in the literature, in which oversimplified models are often applied without discrimination. Generalized conclusions cannot be easily drawn and each case has to be considered with its own peculiarities and constraints. Much remains to be done in this 80-year old field and the new tools at disposal of the researchers, such as efficient synthetic methods (e.g., click chemistry) and modeling platforms for assessing energy transfer processes, for instance, should stimulate originality and incite young scientists to have a try!

Chapter 12

Future prospects

Rakshit Ameta
Department of Chemistry, J.R.N. Rajasthan Vidyapeeth (Deemed to be University), Udaipur, Rajasthan, India

12.1 Introduction

Photochemistry deals with the chemistry of excited states and as such, it includes some interesting reactions, which are not available in chemistry of ground state species. This change in their properties like optical, magnetic, thermal, electrical, electronic, etc. will find numerous applications. Some of them are switching behavior, photochromism, photodynamic therapy & sensors in biomedical fields, solar cells like dye-sensitized solar cells, photochemical reduction of carbon dioxide, etc. All such possibilities have been discussed in brief in this chapter.

12.2 Solar cells

Initial works on DSSCs were mainly focused on the coordination compounds of ruthenium only, but these are highly expensive and hazardous in nature to environment as well as human health, both. Nazeeruddin et al. (1993) could achieve an effieciency of 10.3% using Ru (II) complex as sensitizer. Such materials are still in use inspite of these disadvantages. Coordination compounds of copper can be used in DSSCs as dyes as well as redox mediators in liquid electrolytes along with hole-transporting materials because of their available electronic energy levels. Some zinc, iron and cobalt coordination compounds have also been reported to exhibit potential for DSSC applications. Colombo et al. (2017) reviewed the role of copper complexes in dye-sensitized solar cells as redox mediators.

The Ni(II)-chlorophyll complex was used as a sensitizer for increasing efficiency of solar cells (DSSCs) such as short-circuit current (3.00 mA cm^{-2}), open circuit voltage (0.15 V) and the efficiency (0.20%) (Darmokoesoemo et al., 2017). Cebeci et al. (2021) used ruthenium (II) complex with catechol and boronic acid as anchoring group in dye-sensitized solar cell.

Dye-sensitized solar cells are novel type of solar cells, which has lower toxicity on using coordination transition metal compounds alongwith high

Photochemistry and Photophysics of Coordination Compounds. https://doi.org/10.1016/B978-0-12-824493-7.00005-8
Copyright © 2023 Elsevier Inc. All rights reserved.

power conversion efficiency. It was pointed by Pawlus and Jarosz (2022) that there should be more stress on complex containing Cu, as it can act as both; dyes as well as redox mediators, though coordination compounds of other transition metals can also been commonly used.

12.3 Photochromism

Photochromism is defined as reversible transformation of a chemical species (it may also be called as photoswitching) between two forms by absorbing electromagnetic radiations (photoisomerization), where two forms have different absorption spectra (Irie, 2000; Durr and Bouas-Laurent, 2003). Simply, photochromism has been described as a reversible change of color upon exposure to light.

Mastuda et al. (2004) observed that complexes composed of 1,2-bis(2-methyl5-(4-pyridyl)-3-thienyl) perfluorocyclopentene (bidentate ligand) and 1-(2-methyl-5-phenyl-3-thienyl)-2-(2-methyl-5-(4-pyridyl)-3-thienyl) perfluor ocyclopentene (monodentate ligand) of Zn(II), Mn(II), and Cu(II) undergo reversible photochromic reactions on irradiation with UV and visible lights, alternatively. Chan et al. (2011) studied photochromic behavior of some cyclometalated platinum (II) complexes. These complexes exhibited drastic color changes on photoexcitation due to reversible photochromic behavior. Such a behavior was attributed to the substituents on the pyridyl ring and on extent of π-conjugation of the ligand. Chowdhury et al. (2018) observed photochromic behavior of coordinated 1-alkyl-2- (arylazo) imidazole in silver complex due to light induced trans-to-cis isomerization around a bond.

The effect of molecular packing on photochromic performance was studied by Liu et al. (2021). Three secondary building linkers were introduced into the bipyridinium-based complexes and it was observed that these complexes display photochromic behavior due to photo-induced electron transfer process on UV exposure. Xu et al. (2018) reported photochromic behavior in poly-oxometalate (POM)-based diarylethene (DAE) coordination complex. This complex self-organizes and adopted a molecular dumb-bell structure, which is a prerequisite for the photocyclization reaction. Such an assembly can be found to be switchable between two states in presence of visible light.

Wang et al. (2021) synthesized two new crystalline inorganic-organic hybrid compounds as: $\{[Cd(PCV)_{0.5}(BDC)_{0.5}(H_2O)]\cdot 3H_2O\}_n$ and $\{[Zn(PCV)_{0.5}(BDC)_{0.5}]\cdot 3H_2O\}_n$ solvothermally using viologen analog 1-(4-carboxyphenyl)-4,4′-bipyridinium (PCV) and 1,4-benzenedicarboxylate (BDC^{2-}) ligands. It was reported that both these compounds exhibited photochromism with dramatic decrease of photoluminescence upon irradiation. It was also revealed that powdered sample of zinc complex can deposit easily on paper, when it was diffused into ethanol solution. It was suggested that it may have potential application as an inkless and erasable print medium.

12.4 Photodynamic therapy (PDT)

Photodynamic therapy (PDT) has been developed, where there is possibility of using coordination compounds as photosensitizer, which can first absorb the light and generate some reactive oxygen species (ROS). These complexes can be used as such or in combination with some polymers, non-tubules, metal organic framework (MOFs), etc. It was observed that any interaction between deoxyribosenucleic acid (DNA) and such photosensitizer (coordination compound) may play an important role in development of some new effective anticancer drugs. McKenzie et al. (2019) have excellently reviewed the field of use of coordination compound in photodynamic theory. They have reported that use of coordination compounds in photodynamic theory to develop newer anticancer drugs, as these can have relatively much stronger impact on.

(i) Phototoxic index (PI),
(ii) Amount of ROS generated, and
(iii) Quantum emission efficiency.

The major cases of deaths worldwide are caused by cancer, but in many of the cases, it remained undignosed. Raab (1900) introduced use of photosensitizers in photodynamic therapy (PDT) and his work has increased interest of scientists and medical practitioners all over the globe for treatment of cancer. PDT in specific and it does not damage healthy cells as compared to other method used in treatments of cancer.

Near-IR-emitting and/or efficiently photodynamic water-soluble complexes may hold great application potentials in photodynamic therapy and/or photo detection agents for cancers, but this field has been poorly explored. Zhang et al. (2019) reported solvatochromism, calf thymus DNA binding, and singlet oxygen generation properties of ruthenium(II) complex of visible light $[Ru(bpy)_2(dtdpq)](ClO_4)_2$ **(Ru1)** and a new homoleptic complex of near-IR-emitting $[Ru(dtdpq)_3](ClO_4)_2$ **(Ru2)** (bpy = 2,2′-bipyridine, dtdpq = 2,3-bis(thiophen-2-yl)pyrazino[2,3-f][1,10]phenanothroline) in water. They also discussed DNA photocleavage, singlet oxygen generation in HeLa cells, cellular uptake/localization, and in vitro photodynamic therapy for cancer cells of water-soluble **Ru1**. It was observed that **Ru1** has a potential in photodynamic cancer therapy and as mitochondrial imaging agents while **Ru2** can also find application provided its water solubility can be further improved.

Transition metal complexes are quite interesting for their possible applications as photosensitizers in photodynamic therapy and, photochemotherapy (PCT) (Monro et al., 2018). As Ru(II) polypyridyl complexes have emerged as potential candidates for applications in PDT and PCT; both. They have discussed the principles involved in the development of TLD1433, the first Ru(II)-based photosensitizer for PDT, which has reached to a state of human clinical trial. They have also summarized the future trends and exsiting challenges to use PDT into mainstream of cancer therapy. A photosensitizer

TLD-1433 was found quite successful against non-muscle invasive urinary bladder cancer, which was not responsive to contemporary anticancer therapies (Kaspler et al., 2020).

Geraldes et al. (2021) reported that Mn(III) porphyrins have a great potential as MRI contrast agents, which is Gd-free. It is all due to the fact that the cation and the ligand both have some interesting properties. The redox properties of the Mn(III)-ion can be used for the generation of reactive oxygen species, while porphyrin ligand allowed these complexes to have higher affinity for tumor tissues.

Chemotherapy is used for the treatment of cancer. It is a systemic treatment and therefore, in such treatments, all cells in the body of patient are exposed to cytotoxic effects. On the other hand, photodynamic therapy utilizes same reactive oxygen species such as cytotoxic singlet oxygen ($^1O_2$) to induce cell death in cancer cells, so that PDT is a potential localized method (which can treat several types of cancers by making use of inorganic complexes as photosensitizing agents) (Smith et al., 2022).

Presently, platinum (Pt)-based drug, cisplatin, is still used for chemotherapy in treatment of cancer. As transition metal complexes have unique photochemical and photophysical properties, these can find application in photodynamic therapy as well as photoactivated chemotherapy (PCT), as the photobiological activity is based on energy transfer and electron transfer processes, which makes use of these properties. Different transition metal complexes of Ru(II), Rh(III), Pt(IV), Os(II), Ir(III) copper (0 or I), etc. are either being used in diagnosis and therapy of malignant tumors or are under clinical trial. There is a wide scope for designing, synthesizing and using coordination compound of different metal ions for diagnosis and treatment of cancerous cells of various types. Time is not far off, when some effective solution will be searched out for treatment of this dreadful diseases using transition metal complexes.

12.5 Actinometry

An actinometer is a physical device or chemical system, which determines the number of photons in a beam of light integrally or per unit time. It is also called a dosimeter (Kuhn et al., 2004). It was reported by Allmand and Webb (1929a; 1929b) that potassium ferrioxalate actinometer [$K_3Fe(C_2O_4)_3$] was much more sensitive and convenient as compared to uranyl oxalate actinometer. Uranyl oxalate was used as chemical actinometer because accurate quantum yield determination was made for the photolytic destruction of oxalic acid in the uranyl oxalate aqueous system by Forbes and Heidt (1934). The use of iodide as a chemical actinometer using iodate as an electron scavanger was reported by Rahn (1993, 1997). Goldstein and Rabani (2008) determined the quantum yield of the ferrioxalate and iodide−iodate actinometers using a xenon lamp.

Reinecke's salt has also been used as an actinometer, but it has certain disadvantages.

- Experiments should be carried out in dark,
- Reaction medium is temperature sensitive, and
- Toxic reactant is used such as perchloric acid.

Reinecke's salt still remained an affordable actinometer, particular, when implementation is required at pilot- or industrial -scale photoreactors.

Some other actinometers were reported from time to time by various workers (Heller and Langan, 1981; Brauer et al., 1983; Pitre et al., 2015; Roibu et al., 2018).

12.6 Hydrogen as fuel of future

World is facing the problem of energy shortage. The conventional fuels are on the border line of exhaustion and it has been predicted that fuels will reach almost an end within next two or 3 decades such as coal, petrol, diesel, kerosene, etc. Therefore, it is an urgent requirement of the society to develop some alternate sources of energy, which can fulfill our energy demand for future also. Here, hydrogen enters the scene as hydrogen has high energy storage capability and it can produce electricity, when burnt in fuel cells. Hydrogen can be generated by splitting of water in presence of light. Three-fourth of the world is covered by water, so that at present, there is no shortage of source of hydrogen (water). On burning hydrogen, water is again produced and hence, it is a cyclic process. Therefore, hydrogen is advocated as the fuel of future.

Du et al. (2008) used platinum(II) bi- and terpyridyl chloro complexes [Pt(dcbpy)Cl_2 and [Pt(ttpy)Cl]$^+$], [dcbpy = 4,4′-dicarboxyl-2,2′-bipyridine and ttpy = 4-tolyl-2,2′:6′,2″-terpyridine] for photocatalytic production of hydrogen from water. They used methanol or triethanolamine (TEOA) as sacrificial electron donors, and titanium dioxide as an electron relay. It was observed that good sizable amounts of H_2 could be achieved on UV exposure. It was also suggested that the these complexes are simply acting as precursors to platinum colloids that act as the H_2 generating catalyst.

Zarkadoulas et al. (2012) reviewed use of dithiolene complexes as photocatalysts for the photosplitting of water. As these photocatalysts are not much stable in homogeneous solutions and therefore, heterogeneous approach can be applied by anchoring these catalysts on semiconductor or they can be deposited on an electrode in electrocatalytic cell. Such dithiolene complexes composed of some abundantly available and inexpensive metals can replace most expensive platinum for generation of hydrogen.

Lv et al. (2016) reported the synthesis of four Fe bis(benzenedithiolate) complexes. These complexes exhibited catalytic activity for generation of hydrogen, when water-soluble CdSe QDs and ascorbic acid were used as

photosensitizer and sacrificial electron donor, respectively under visible light (520 nm). It was also revealed that the highest activity was exhibited by the complex with the most electron-donating dithiolene ligand.

Inoue et al. (2017) synthesized three Schiff-base-type nickel(II) complexes and corresponding noninnocent-type complexes. They also evaluated their catalytic ability for the photoproduction of hydrogen from water. It was revealed that Schiff-base-type complex with chlorine atoms and noninnocent-type complex with methyl groups on the pendant phenyl rings exhibited higher activity with turnover numbers of four hundread or more. Kadassery et al. (2017) used $[Mn(CO)_3(\mu 3{-}OH)]_4$ tetramer to produce CO, H_2 and hydrogen peroxide (products) in photosplitting of water. It may develop some new strategies for water-splitting reactions using organomanganese complexes.

Some organometallic compounds based on iridium(III) and metal complexes have exhibited some interesting features (Tritton et al., 2022) such as:

- Wide range of versatile chemical structures,
- Unique photophysical properties, and
- Photocatalytic capabilities.

They have also discussed design and evaluation of these compounds as photocatalysts/photosensitizers for production of hydrogen, photocatalytically and suggested some guidelines for design of more efficient and robust photocatalytic systems in future.

Panagiotakis et al. (2019) studied the behavior of a thiosemicarbazone-nickel (II) complex (NiTSC-OMe) as a molecular catalyst for photo-induced production of hydrogen. They used three photosesnsitizers $[ZnTMePy]PCl_4$, $[Ir(ppy)_2(bpy)]PF_6$, and $[Ru(bpy)_3]Cl_2$. It was reported that the system was found to be most efficient, when NiTSC-OMe and $[Ir(ppy)_2(bpy)]PF_6$ were used as catalyst and chromophore, respectively.

12.7 Reduction of carbon dioxide

The global warming and scarcity of energy resources is an existing challenge for scientists all over world. A search is therefore necessary for some alternate strategy to combat against these rapid and ever increasing problems. The conversion of CO_2 into useful synthetic fuels or chemicals through photocatalytic process is an eco-friendly and economical strategy just to achieve a sustainable energy supply. The carbon dioxide can be reduced to variety of products such as HCOOH, HCHO, CO, CH_3OH, CH_4, C_2H_4, C_2H_5OH, etc. Although kinetic barrier increases with the increase of electrons and protons, the reduction of CO_2 to formaldehyde/methanol/methane/ethane is still more difficult as compared to formic acid or CO.

Developing photocatalytic systems for CO_2 reduction will provide useful and energy-rich compounds and would be one of the most important focuses in the field of “artificial photosynthesis” and “solar fuels”. Such studies have

been conducted in the past 3 decades from the perspective of basic science and for solving the problem of shortage and dependence on fossil resources. Yamazaki et al. (2015) reviewed the photocatalytic reduction of carbon dioxide using some metal complexes as photocatalyst and/or photosensitizer.

They discussed the photocatalytic abilities of these three categories.

- Multicomponent systems having photosensitizer and photocatalyst,
- Supramolecular photocatalysts comprising a multinuclear complex, and
- Hybrid systems with metal-complex photocatalysts and inorganic materials.

Fujita (1999) reported the use of transition-metal complexes $Ru(bpy)_2(CO)Xn+$ (bpy = 2,2′-bipyridine, X = CO, Cl, H, etc.), and $CoHMD^{2+}$ (HMD = 5,7,7,12,14,14-hexamethyl-1,4,8,11-tetraazacyclotetradeca-4,11-diene) for photochemical reduction of carbon dioxide.

Liu et al. (2020) reviewed the use of complexes of non-noble metals (Ni, Co, Cu, Fe, and Mn) as molecular catalysts for photochemical CO_2 reduction. It was opined that modification in structure of ligand can also be effective in improving the catalytic performance of complexes (Fig. 12.1).

Obermeier et al. (2021) reported light-driven CO_2 reduction using [Cu(xant)(bcp)]+, (xant = xantphos, bcp = bathocuproine) or $Ir(dFppy)_3$ [dFppy = 2-(4,6-difluorophenyl)pyridine] as photosensitizer. They used triethylamine (TEA) as sacrificial electron donor. The 3d metal catalysts have either dptacn (dipicolyl-triazacyclononane, LN3) or dpdatcn (dipicolyl-diazathiocyclononane, LN2S) as ligands with central metal ion as Fe^{3+}, Co^{3+} or Ni^{2+}. It was suggested that nature of ligand, metal center and composition of solvent influences the selectivity in product formation, meaning that it can be solely H_2 or CO or a mixture of both. The ratio between these two products can be controlled by the right choice of reaction conditions.

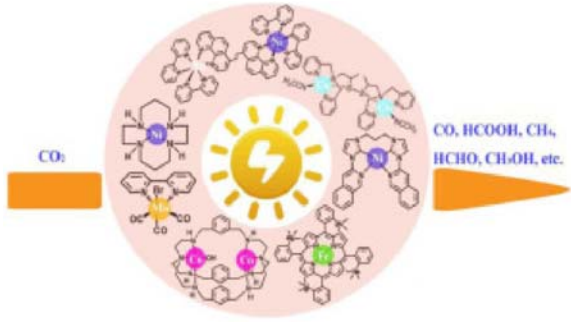

FIGURE. 12.1 Photochemical reduction of carbon dioxide. *Adapted from Liu, D.C., Zhong, D.C., Lu, T.B., 2020. Non-noble metal-based molecular complexes for CO_2 reduction: from the ligand design perspective. EnergyChem 2 (3). doi:10.1016/j.enchem.2020.100034. With permission.*

Kumagai et al. (2022) developed various stable, highly efficient, and selective photocatalytic systems for reduction of CO_2. They used transition metal complexes as photosensitizers as well as catalysts. A mixed system containing ring-shaped Re(I) trinuclear complex (photosensitizer) and fac-[Re(bpy)$(CO)_3\{OC_2H_4N(C_2H_4OH)_2\}$] (catalyst) was used, which selectively photocatalyzed reduction of CO_2 to CO with 82% quantum yield and a high turnover number (600). Not only this, other earth abundant ions, such as Fe(II), Cu(I), and Mn(I) can also be used as central metal cations. When Cu(I) dinuclear complex was taken as a photosensitizer and fac-Mn(bpy)$(CO)_3Br$ as a catalyst, then the total formation quantum yield of CO and HCOOH was 57% and TON was more than 1300.

12.8 Others

A number of complexes exhibited stability toward photodecomposition, but they can undergo excited state redox processes, finding applications in interconversion of chemical energy and light. A combination of photochemistry with supramolecular chemistry can help in designing and fabrication of some multicomponent systems, capable of performing light induced functions. Such photoreactive or luminescent metal complexes can be used in different molecular devices and machines, which can process light signals and molecular machines (Balzani et al., 2008).

As some complexes are photosensitive, they undergo photoaquation reaction, where one of the ligand is replaced by water. Then this water can be exchanged by some other anionic ligand. Sodium nitroprusside contains cyanide ligand, which cannot be easily replaced by other ligands. Sodium nitroprusside has been investigated in this context, where CN^- can be replaced and metabisulphite entered the coordination sphere developing a blue colored complex. It was reported that the amount of ligand can also be estimated spectrometrically within desired limits (Mehta et al., 2003).

Different valence isomers are generated by metal-to-metal charge transfer with markedly different electronic configurations. In particular, because of this transfer, the spin states of single-metal sites and their coupling interactions will also change the symmetry in charge distribution. As a result, significant changes are there, in both; magnetic as well as electric properties of material. Not only this, MMCT affects bond length and absorption spectra, and therefore, some thermal expansion and photochromic behavior can be observed. Such materials having MMCT are potential candidates for switchable multifunctional devices with synergistic responses. Meng et al. (2018) reviewed use of MMCT units as actuators for tuning electric, magnetic, thermal expansion, and photochromic properties and they have also discussed existing challenges and future aspects of this field.

Molecular transition metal ligand complexes are emerging as promising systems in materials science as with different oxidation states coordination

numbers and geometries, and metal d electron configurations, they can undergo electronic transitions. Metal-to-ligand charge-transfer transitions provide them interesting rich redox properties as well as robustness. The properties can be tuned by appropriate selection of strong π-acceptor ligands and low-valence metal centers. They have light-harvesting properties and applications in photocatalysis, and as such, these transition metal complexes can be used as useful materials in phosphorescent organic light-emitting diodes as well as resistive memory devices (Yan et al., 2020).

The photochemistry and photophysics of coordination compounds of actinide ions (An^{n+}) and actinyl ions (AnO_2^{n+}) have been nicely reviewed by Natrajan (2012), almost a decade back. Mostly photochemistry of uranyl(VI) ion has been studied extensively, but photochemistry of other actinides remained less explored, may be due to instability of these ions as most of the actinide elements are undergo radioactive disintrigration. As such, photochemistry of complexes of actinides is not fully understood and it needs further progress in this direction.

Photochemistry and Photophysics of Coordination Compounds

Fundamentals and Applications

Rakshit Ameta, Avinash Kumar Rai, Jayesh P. Bhatt, Shipra Bhardwaj and Suresh C. Ameta

A structured guide to the photochemical and photophysical properties of coordination compounds for a wide range of applications.

Coordination complexes offer a huge range of interesting properties, and understanding the differing photochemical and photophysical characteristics of complexes with different metal centers, will allow researchers to understand behaviors, compare available options, and make the best selection for their specific needs. *Photochemistry and Photophysics of Coordination Compounds* provides a systematic overview of the photochemical and photophysical properties of coordination compounds with different metal cores.

Beginning with a clear introduction to the fundamentals of both, photochemistry and coordination chemistry, the book goes on to outline the photochemical and photophysical properties of a large range of coordination compounds, clustering metal cores together in chapters according to their periodic table group, ranging across transition metals, lanthanides, and actinides. In addition to outlining their properties, each chapter discusses the synthesis, current applications, and future potential of coordination compounds in each group.

Drawing on the experience of a global team of experts, *Photochemistry and Photophysics of Coordination Compounds* is an authoritative guide for all those interested in understanding and harnessing the photochemical properties and potential applications of coordination complexes for their own work.

Key Features

- Introduces the fundamentals of both: photochemistry and coordination compounds
- Supports learning through carefully structured content, with chapters uniquely arranged by group of periodic table
- Bridges the knowledge gap between theory and practice by presenting application examples in each chapter

1. Introduction 1
Suresh C. Ameta

1.1 Introduction 1
1.1.1 Advantages 2
1.1.2 Disadvantages 3
1.2 Unique features of quantum dots 3
1.2.1 High surface-to-volume ratio 3
1.2.2 Surface plasmon resonance 3
1.2.3 Quantum confinement effect 4
1.3 Classification of quantum dots 4
1.3.1 Core-type quantum dots 4
1.3.2 Core–shell quantum dots 5
1.3.3 Alloyed quantum dots 5
1.4 Synthesis of quantum dots 8
1.4.1 Top-down approach 8
1.4.2 Bottom-up approach 9
1.4.3 Methods of synthesis 9
1.5 Applications of quantum dots 9
1.5.1 Solar cells 10
1.5.2 Sensors 11
1.5.3 Light emitting diodes 11
1.5.4 Photocatalysis 11
1.5.5 Hydrogen generation 12
1.5.6 Biomedicals 12
1.6 Conclusion 13
References 13

2. Hydrothermal synthesis of quantum dots 15

7. Microwave-assisted synthesis of quantum dots 115
Chetna Ameta, Yogeshwari Vyas, Priyanka Chundawat and Dharmendra

7.1 Introduction 115
7.1.1 Advantages 116
7.1.2 Disadvantages 117
7.2 Synthesis of core-type quantum dots 117
7.2.1 Oxide quantum dots 118
7.2.2 Sulfide quantum dots 122
7.2.3 Selenide quantum dots 126
7.2.4 Telluride quantum dots 127
7.2.5 Other quantum dots 129
7.3 Synthesis of core–shell quantum dots 130
7.3.1 Type I CS quantum dots 131
7.3.2 Inverse type I CS quantum dots 131
7.3.3 Type II CS quantum dots 132

7.3.4 Inverse Type II CS quantum dots 132
7.3.5 Core–shell–shell quantum dots 132
7.4 Synthesis of alloyed quantum dots 133
7.5 Carbon and graphene quantum dots 135
7.6 Recent developments 135
7.7 Conclusion 136
References 136

8. Sonochemical synthesis of quantum dots 147
Garima Ameta and Seema Kothari

8.1 Introduction 147
8.1.1 Advantages 148
8.1.2 Disadvantage 149
8.2 Instrumentation 149
8.3 Synthesis of quantum dots 149
8.3.1 Metals 149
8.3.2 Metal oxides 151
8.3.3 Metal sulfides 153
8.3.4 Selenides 157
8.3.5 Tellurides 158
8.3.6 Carbon-based quantum dots 159
8.3.7 Others 162
8.4 Conclusion 163

About the editors

Dr. Rakshit Ameta has a thoroughly first class career, securing first position in his MSc. and was awarded a Gold Medal. He was also given the Fateh Singh Award from Maharana Mewar Foundation, Udaipur for his meritorious performance. After completion of his PhD, he served in Hindustan Zinc Limited, Vedanta Group for 1 year. He has served in M.L. Sukhadia University, Udaipur; University of Kota, Kota, PAHER University, Udaipur, and presently is at J.R.N. Rajasthan Vidyapeeth (Deemed to be University) Udaipur. Under his supervision 12 PhD students have been awarded PhDs on various aspects of Green Chemistry. He has around 140 research publications to his credit in journals of national and international repute. He has a patent to his credit as well. He is a reviewer of around 50 international journals. Dr. Rakshit has successfully organized many National Conferences at University of Kota, Kora; PAHER University, Udaipur; and J.R.N. Rajasthan Vidyapeeth, Udaipur. He has delivered Invited lectures and chaired sessions in 20 national conferences in different parts of the country. Dr. Rakshit has served as a council member (2011−13 and 2020−22) and associate editor, Physical Chemistry Section (2014−16), scientist-in-charge in the Industrial and Applied Chemistry Section (2014−2016) of the Indian Chemical Society, Kolkata, and executive council member (2012−14) and Zonal Secretary (2016−18) of Indian Council of Chemists, Agra. He had been a recipient of the Dr. U.C. Pant Memorial Award, Indian Chemical Society, Kolkata. He has written six books published by Taylor & Francis, UK; Academic Press, Elsevier; Apple Academic Press, and a number of chapters in books by these publishers and also Nova Publishers; Trans-Tech Publications, Springer, etc. His main research focus is on photochemistry, green chemistry, microwave-assisted reactions, environmental chemistry, wastewater treatment, nanochemistry, solar cells, bioactive & conducting polymers.

Dr. Jayesh P. Bhatt received his MSc. from RSTM Nagpur University in 2011. He was awarded his PhD in the year 2019 from PAHER University, Udaipur. Since 2019 he has been working as an assistant professor in the Department of Chemistry, PAHER University, Udaipur. He has done research in the field of nanomaterials, particularly quantum dots, wastewater treatment, etc. Dr. Jayesh has published 11 research articles in journals of

national and international repute and contributed 12 chapters. Currently four PhD students are working under his supervision. He has been honored with the Young Scientist Award at an international conference in 2018, Best Poster Presentation in 2019, Best Oral Presentation in 2020, and Senior Scientist Award for Best Oral Presentation in an international conference (2021).

Prof. Suresh C. Ameta obtained his master's degree from the University of Udaipur and was awarded a gold medal in 1970. He obtained his PhD degree from Vikram University in 1980. He has served as professor and head, Department of Chemistry, North Gujarat University Patan (1994) and M.L. Sukhadia University, Udaipur (2002−05) and head, Department of Polymer Science (2005−08). He also served as dean, P.G. Studies for a period of 4 years (2004−08) in M.L. Sukhadia University, Udaipur and dean, Faculty of Science, PAHER University (2011−18). Now, he is serving as professor of eminence (distinguished professor), Faculty of Science, PAHER University, Udaipur. Prof. Ameta has around 50 years of experience of teaching and research. He has successfully guided 108 students through their PhDs. Prof. Ameta has occupied the prestigious position of President, Indian Chemical Society, Kolkata (2000−01) and is now a lifelong advisor. He was awarded a number of prizes during his career, including the National prize twice for writing chemistry books in Hindi, Prof. M.N. Desai Award, Prof. W.U. Malik Award, Scientist of the Year Award, National Teacher Award, Prof. G.V. Bakore Award, and above all, Life Time Achievement Awards from the Indian Chemical Society (2011), Kolkata, Indian Council of Chemists, Agra (2015) and Association of Chemistry Teachers, Mumbai (2018). Dr. Ameta has more than 400 research papers and 36 books to his credit. He has contributed chapters in books published by Trans-Tech, Switzerland; Nova Science; Taylor & Francis; Elsevier; Springer; and Apple Academic Press. He has 12 books to his credit, including Green Chemistry, Microwave Assisted Organic Synthesis, Solar Energy Conversion and Storage, Group Theory, Photocatalysis, Storage, Advanced Oxidation Processes for Waste Water Treatment, Sonochemistry, etc. The Indian Chemical Society, Kolkata published a special issue of the Journal of Indian Chemical Society on his 60th birthday in 2008 and also instituted a National Prize in his honor as the Prof. Suresh C. Ameta Award to be given to a Senior Scientist of the country from 2003 onwards.

Preface

Nanomaterials have revolutionized many research areas due to their unique optical, electronic, and other properties. Quantum dots have lower dimensions (2−10 nm) in the nanometric range. These quantum dots have a high surface area-to-volume ratio, a quantum confinement effect, and surface Plasmon resonance. As such they have great potential for applications in different fields. The present book is divided into three parts. First, it deals with the basics or fundamentals of quantum dots, while the second part is devoted to various methods of synthesizing quantum dots, including hydrothermal, sol−gel, laser ablation, coprecipitation, biogenic, microwave-assisted, and sonochemical. The third part of the present book is devoted to the possible applications of quantum dots in these areas, such as photocatalysis, solar cells, light-emitting diodes, sensors, photosplitting of water, targeted drug delivery, cancer therapy, etc. The time is not far off when quantum dots will find a firm footing, and they will be considered a miracle particle in the years to come.

Chapter 1

Introduction

Suresh C. Ameta
Department of Chemistry, PAHER University, Udaipur, Rajasthan, India

1.1 Introduction

The materials in the nanorange (1−100 nm) are termed as nanomaterials. There are some nanostructured materials with size in the 2−10 nm range, such nanomaterials are called quantum dots. The name quantum dot was given because it is a tiny speck of matter (2−10 nm), which is very small, just like a single point or dot. In other words, it is considered zero-dimensional. The particles inside the quantum dot that carry electricity (electrons and holes) are trapped (constrained) and have well-defined energy levels, following the laws of quantum theory just like individual atoms. There are a few dozen to hundreds or a few thousand atoms. Although these quantum dots are nanocrystals, they behave more like individual atoms; therefore, they have been nicknamed artificial atoms also.

Quantum dots have quantized energy levels. On excitation an electron in the quantum dot jumps to a higher energy level. When this excited electron returns to a lower level, the quantum dot emits a photon of light with the same energy as was originally absorbed. The color of the emitted light depends on the energy levels and it varies from one quantum dot to another. The energy levels of quantum dots are governed by their size and not the substance from which it was made. The quantum dots and their application have been excellently reviewed by different researchers (e.g., Jamieson et al., 2007; Jacak et al., 2013; Michler, 2003; Wu et al., 2019; Molaei, 2019; Divsar, 2020; Nair et al., 2020; Abd Rani et al., 2020; Vyas et al., 2021).

A small quantum dot has a longer bandgap, and hence it requires more energy to excite its electron. As the frequency of emitted light is proportional to the energy, smaller quantum dots emit radiation of higher energy or frequency, that is, shorter wavelengths, while larger quantum dots have closely spaced energy levels and emit photons of lower energy or frequency, that is, longer wavelengths. It means that as the size of quantum dots increases, the quantum dot will emit photons with lower energy or frequency and higher wavelength and vice versa. This is presented in Fig. 1.1.

Quantum Dots. DOI: https://doi.org/10.1016/B978-0-12-824153-0.00001-X
© 2023 Elsevier Inc. All rights reserved.

When the size of the quantum dot is greater (diameter 5−6 nm), then it will emit radiation of larger wavelengths with orange or red colors. On the other hand, if the size of quantum dot is smaller (diameter 2−3 nm), then it will emit radiation of shorter wavelengths with blue and green colors. But the actual color depends on the exact size and composition of the quantum dots. Accordingly, a change in color can be observed as the particle size of quantum dots varies. This is clearly visible in Fig. 1.2.

1.1.1 Advantages

These are some advantages of quantum dots and these are:

- High quantum yield
- High photostability
- Symmetric and narrow peak of emission

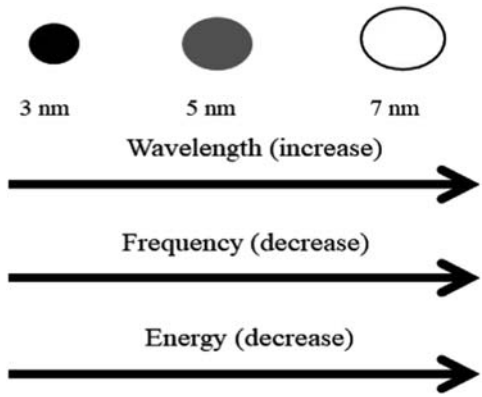

FIGURE 1.1 Relationship between size of quantum dots, energy or frequency of emitted light, and wavelength of radiation.

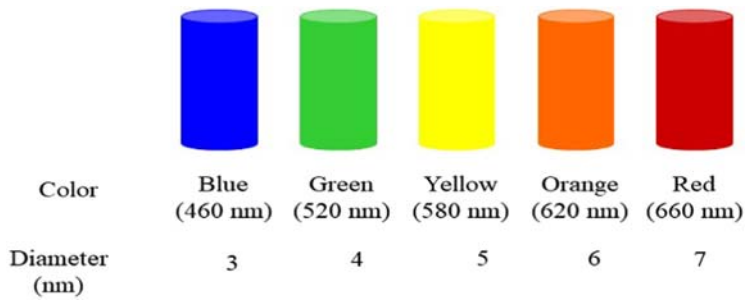

FIGURE 1.2 Change in color with size of quantum dots.

- Longer lifetime
- Possibility to control emission by changing the size and structure of quantum dots
- Brightness
- Resistance to photobleaching as compared to organic fluorophores
- Required small amount of energy for excitation (blue or UV radiation)

1.1.2 Disadvantages

Apart from the advantages, there are some disadvantages of quantum dots such as:

- High toxicity, when used in vivo
- Decline of fluorescence exponentially
- Blinking of quantum dots makes them invisible sometimes
- Quantum yield deterioration
- Extended lifetime may create a problem when rapid degradation is required

1.2 Unique features of quantum dots

Various properties of nanomaterials or quantum dots change as their size is changed. At this stage, the percentage of atoms available at the surface of a semiconducting material becomes quite significant. There are three main factors that are considered responsible for some unique properties in nanomaterials as well as quantum dots, which are significantly or totally different from their counterpart micro-, macro-, or bulk materials. These are:

1.2.1 High surface-to-volume ratio

As the size of the particle approaches a few nm, the surface area-to-volume ratio and surface-to-bulk atom ratio both increase dramatically. Depending on the composition and structure of the material used to produce nanoparticles or quantum dots, properties like absorption or emission wavelength, solubility, transparency, color, catalytic behavior, conductivity, melting point, etc. are changed only by variation in the size of the particle. It leads to some interesting behaviors of quantum dots.

1.2.2 Surface plasmon resonance

Surface plasmon resonance (SPR) is the collective oscillation of valence electrons in a solid stimulated by incident light. Such a resonance condition is established whenever the frequency of light photons matches the natural frequency of oscillating surface electrons against the restoring force of the positive nuclei. This SPR in nanometric structures is termed as localized

SPR (LSPR). LSPRs are collective oscillations of electron charge in metallic nanoparticles or quantum dots that are excited by light. Solutions containing nanoparticles or quantum dots of metals (gold, silver, etc.) are colored due to the SPR of the particles. Some properties like conductivity, dispersible nature, catalytic behavior, optical properties, etc. change with different surface properties of the particle.

1.2.3 Quantum confinement effect

The quantum confinement effect can be observed once the diameter of any material reaches the same magnitude as the de Broglie wavelength of an electron wave function. When materials are so small, their electronic and optical properties deviate substantially from those of bulk materials. Here, energy levels are not continuous but are quantized, that is, discrete, and therefore these materials in the range of nanosize or the size of quantum dots exhibit the quantum confinement effect.

1.3 Classification of quantum dots

Quantum dots are classified mainly into three types and these are:

- core-type quantum dots,
- core−shell quantum dots (CSQDs), and
- alloyed quantum dots.

1.3.1 Core-type quantum dots

These quantum dots can be single component materials, which have uniform internal compositions. The properties of these core-type nanocrystals such as photo- and electroluminescence can be fine-tuned just by simply changing the crystallite size. The examples of core-type quantum dots are chalcogenides (sulfides, selenides, or tellurides) of metals like cadmium, zinc, or lead (Fig. 1.3).

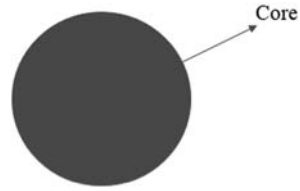

FIGURE 1.3 Core-type quantum dots.

1.3.2 Core–shell quantum dots

The luminescent properties of quantum dots are due to recombination of electron–hole pairs (excitons) through radiative pathways. The decay of an exciton can also occur via nonradiative methods, which reduces the fluorescence quantum yield. One of the possible methods to improve efficiency and brightness of these nanocrystals is to grow a shell of a semiconducting material with higher bandgap around it. Such particles, where small regions of one material are embedded in another with a wider bandgap, are termed CSQDs or core–shell semiconducting nanocrystals (Fig. 1.4). If the order is reversed, then they are called reverse type quantum dots, where a shell is inside the core structure (Fig. 1.5). Coating of quantum dots with some shells improves the quantum yield just by passivizing nonradiative recombination sites. This also makes them more robust to processing conditions, so that they can find use in various applications. CSQDs are classified into two types:

- Core–shell type-I quantum dots (Figs. 1.6 and 1.7)
- Core–shell type-II quantum dots (Figs. 1.8 and 1.9)

1.3.3 Alloyed quantum dots

Although electronic and optical properties of a quantum dot can be tuned by just changing its crystallite size, even then some problems are faced in many applications wherever there are some restrictions on size. Properties of

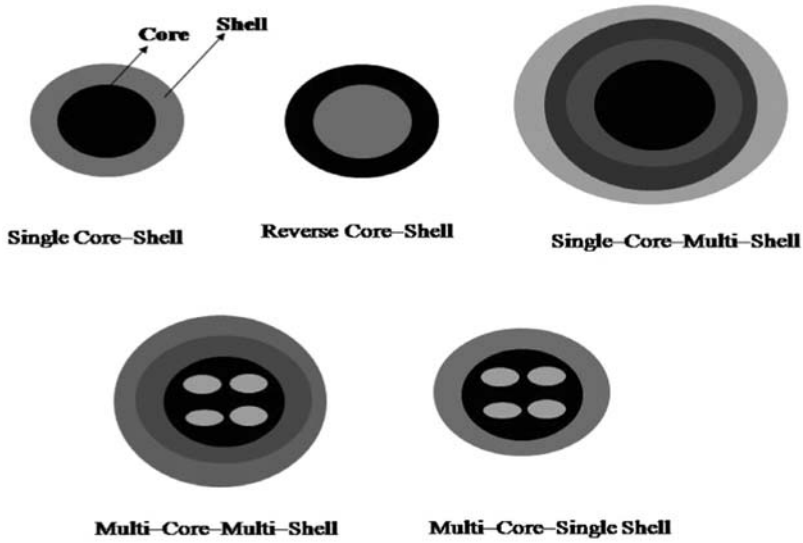

FIGURE 1.4 Core–shell type quantum dots with various arrangements of core–shell.

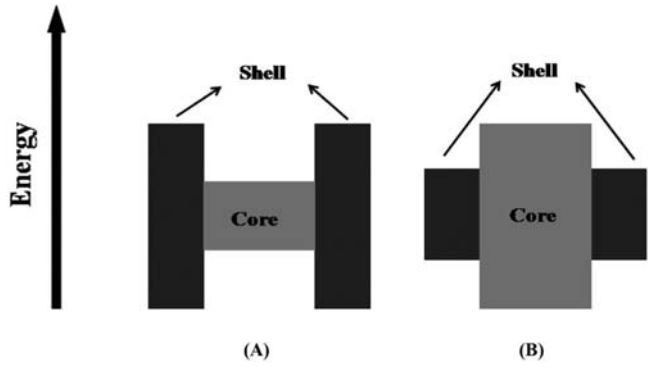

FIGURE 1.5 Core−shell type−I: (A) normal, and (B) reversed quantum dots.

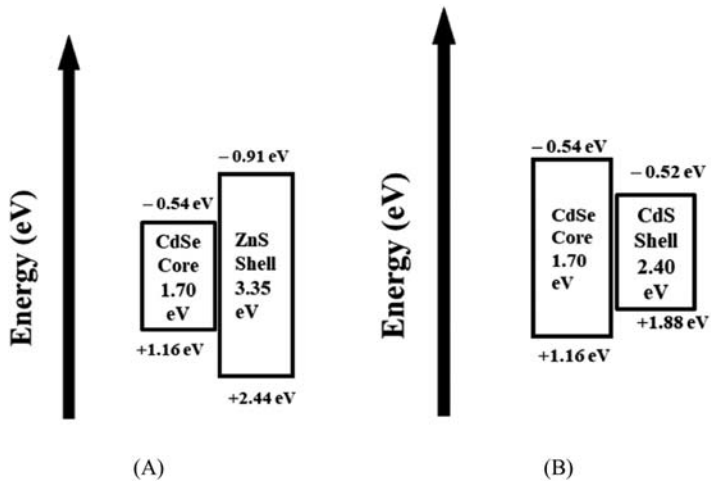

FIGURE 1.6 Energy diagram of core−shell type−I: (A) normal and (B) reversed quantum dots.

quantum dots having multicomponents can be tuned without any change in crystallite size. Such multicomponent systems are called alloyed quantum dots (homogeneous and gradient internal structures) and it is possible to tune their electronic and optical properties by changing their internal structure and composition. These alloyed quantum dots are fabricated by alloying any two semiconductors with different bandgaps (Fig. 1.9). These quantum dots show some interesting properties, which are sometimes very different from the properties of their original bulk counterparts or parent semiconductors. They can be homogeneous in nature or with a particular zone rich in a specific element.

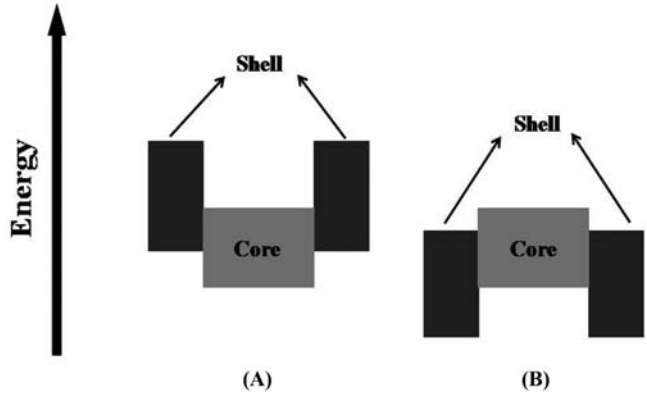

FIGURE 1.7 Core–shell type–II quantum dots. (A) Both the bands (conduction and valence) of shell are higher than core and (B) Both the bands of shell are lower than the core.

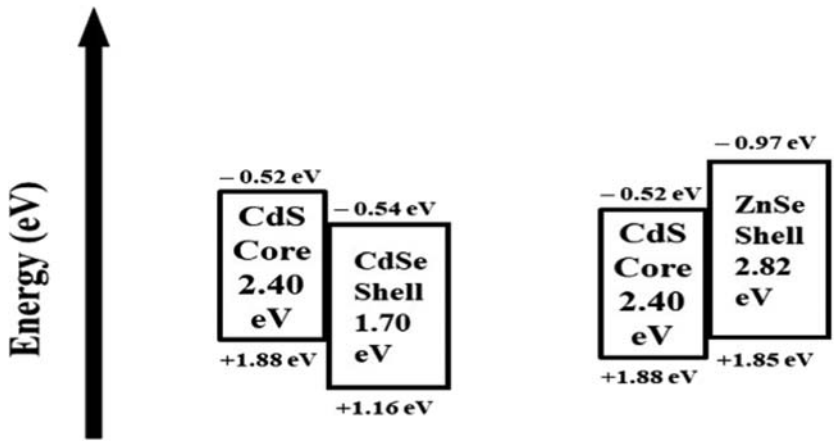

FIGURE 1.8 Energy diagram of core–shell type–II quantum dots.

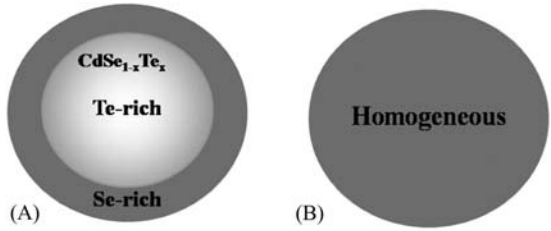

FIGURE 1.9 (A) Specific element (Te- or Se-) rich alloyed quantum dots, and (B) homogeneous alloyed quantum dots.

1.4 Synthesis of quantum dots

A number of routes have been developed for the synthesis of QDs with controlled size, shape, structure, and dimensionality, but generally used techniques are categorized into two approaches:

- top-down approach; and
- bottom-up approach.

New physical properties and applications of nanomaterials are only possible when nanostructured materials are made available with the desired size, shape, morphology, crystal structure, and chemical composition.

1.4.1 Top-down approach

The top-down approach involves breaking the bulk material into nanosized structures or particles. This approach is based on physical methods (Fig. 1.10). These are nothing but an extension of those methods, which are used for producing micro-sized particles. Top-down approaches are relatively simpler as they depend either on the removal/division of the bulk material or on miniaturization of any bulk process of fabrication to produce the nano-desired structures. But there is a problem with this approach, that is, the surface structure prepared is imperfect in nature. Nanostructured materials prepared by this approach are not smooth and have structural defects on the surface and also contain a number of impurities. Examples of such top-down techniques are high-energy wet ball milling, laser ablation, electron beam lithography, liquid phase exfoliation, atomic force manipulation, gas-phase condensation, and aerosol spray.

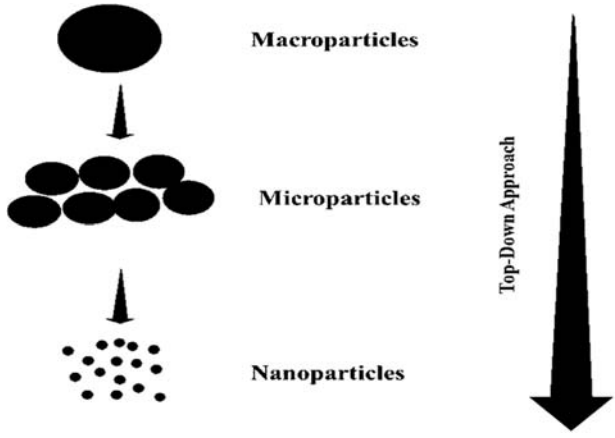

FIGURE 1.10 Top-down approach.

1.4.2 Bottom-up approach

Another approach for this purpose is the bottom-up approach (Fig. 1.11). These are mostly chemical-based methods. These are economical also. This approach builds up a material starting from the bottom, that is, atom-by-atom, molecule-by-molecule, cluster-by cluster, etc. Some of the examples are sol−gel synthesis, hydrothermal synthesis, electrodeposition, organometallic chemical route, reverse-micelle route, colloidal precipitation, and template-assisted sol−gel.

1.4.3 Methods of synthesis

Different methods are available for the synthesis of quantum dots. These are:

- Hydrothermal method
- Sol−gel method
- Laser ablation method
- Coprecipitation method
- Biogenic method
- Microwave-assisted method
- Sonochemical method

1.5 Applications of quantum dots

Although there are numerous applications of quantum dots covering a wide range, the main applications include:

- Solar cells
- Biolabeling
- Bioimaging

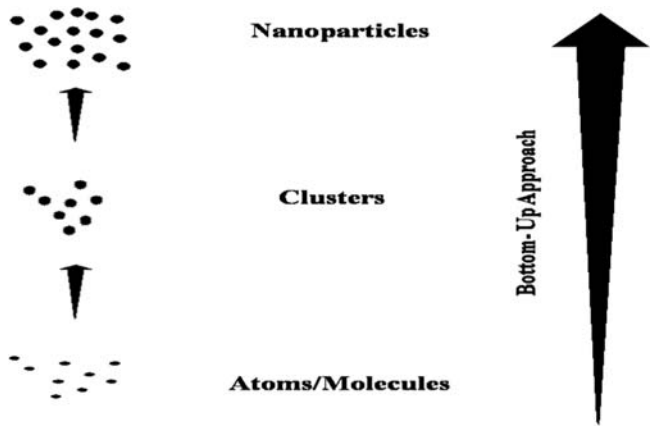

FIGURE 1.11 Bottom-up approach.

- Cancer therapy
- Chemical and biosensors
- Microscopy
- Lasers
- Inkjet printing
- Spin coating
- Photosplitting of water to generate hydrogen
- Light-emitting diodes
- Wastewater treatment using photocatalysts
- Photothermal and photodynamic therapy
- Targeted drug delivery,

This list is not complete and many more new applications will emerge in years to come. Some major applications of quantum dots are depicted in Fig. 1.12.

1.5.1 Solar cells

The world is facing a scarcity of energy resources, as the conventional fuels are either exhausted or reaching an end within the coming few decades. Therefore, there is an urgent demand to search for or to develop some new alternate resources, which are likely to fulfill the demand of the society in forthcoming years. Many attempts have been made in this direction, where sunlight has been used as the source of energy to generate electrical energy.

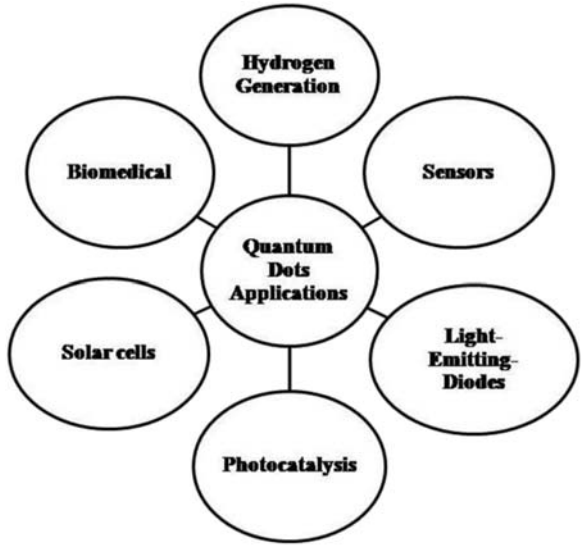

FIGURE 1.12 Different major applications of quantum dots.

It is very important to find some low-cost materials for the conversion and storage of solar energy with good conservation efficiency and long-term storage. Various solar cells are available, such as photovoltaic cells, photogalvanic cells, dye-sensitized solar cells, etc. Nanomaterials are already in use in solar cells, but now quantum dots are also being utilized in some solar cells to increase the efficiency of these cells and prolong their lifetime. Quantum dots sensitized solar cells have become a topic of interest these days, because of some unique properties of quantum dots. The use of pervoskites has also added a new dimension to the field of solar cells.

1.5.2 Sensors

Sensing a particular material or conditions has become a field of general interest in society. There is a long history for developing different and active sensors that can sense the presence of harmful chemicals; but now the presence of nanomaterials or quantum dots has added newer dimensions to the field of sensors. Sensing a specific chemical at ppm or sometimes even at ppb level has become possible by the use of quantum dots, for example, alcohol, ammonia, pesticides, carbon dioxide, nitrogen peroxide, hydrogen sulfide, liquefied petroleum gas (LPG) commonly used drugs (antibiotics, antiseptic, antiinflammatories, antipyretics, etc.), etc. Apart from this, these quantum dots also sense any small variation in the surroundings or environment (chemical and biological) and these can be used for measuring the temperature and humidity of a particular room or area.

1.5.3 Light emitting diodes

Whenever current flows in a semiconductor, electrons and holes recombine. As a result, energy is released in the form of photons. Thus the semiconductor becomes a light source and it is called a light-emitting diode light. Quantum dots are used in fabricating such light-emitting diodes. They can give a variety of colors: green, blue, red, orange, yellow, etc. apart from white. This color depends on the bandgap of that semiconductor, that is, corresponding to the energy of photons. Normally, electrical energy is first converted into heat then into light, but light-emitting diodes convert electrical energy directly into light so that no or negligible electricity is wasted in the form of heat. LEDs find application in a number of areas such as display and lighting (different colors), night vision (security cameras), data communication, agriculture and horticulture (plant growth and improved crop production), antimicrobial properties, etc.

1.5.4 Photocatalysis

Photocatalysis has a beauty in that it can provide the oxidizing as well reducing environment simultaneously in the same vessel, which is not otherwise

possible with any oxidant or a reductant, which gives only one kind of environment. Instead, the oxidant and reductant will react (if both are present there) with each other rather than attacking a particular molecule or entity. It can generate a very strong oxidizing species, hydroxyl radicals in the majority of cases, which are quite effective in degrading the organic pollutants to less harmful or almost harmless end products. Thus the use of quantum dots in photocatalytic degradation can be useful in the complete mineralization of water and air contaminants like dyes, pharmaceuticals, pesticides, nitro and chloro compounds, endocrine-disrupting chemicals, phenols, carbon dioxide, carbon monoxide, nitrogen dioxide, etc. Not only this, quantum dots are now utilized in the photoreduction of carbon dioxide to some useful chemicals, which can be used as synthetic fuels such as methanol or methane. This will solve the problem of the energy crisis on one hand and decrease the amount of carbon dioxide in the atmosphere; thus placing a control on the ever increasing global warming.

1.5.5 Hydrogen generation

The shortage of natural energy resources is becoming a burning problem in the world these days and it is likely to increase exponentially in the coming future. The requirement for energy is regularly increasing and it will be very difficult to depend for a long time on the natural fuels such as wood, coal, kerosene, diesel, petrol, natural gas, or LPG, and therefore there is a pressing demand that some alternative should be developed that can fulfill the demand for energy from society in coming decades. Here, hydrogen enters the scene, It has a high energy storage capacity and can be used as an alternative fuel. It has been predicted to be the fuel of the future. It is presently produced by the consumption of electricity, which is a costly affair. It has been advocated that hydrogen should be generated by the splitting of water photocatalytically in the presence of a light source, and the most preferred one is sunlight, as it freely available at present and it is inexhaustible also. It can be utilized as a source of energy for the future at relatively low cost. The source of hydrogen is water, which is abundantly available, covering almost three-fourths of the Earth, and the final product of its combustion is water again, which is harmless Now, quantum dots are being used in photocatalytic splitting of water to produce hydrogen with relatively high efficiency.

1.5.6 Biomedicals

Quantum dots have great potential for application in the biomedical and biotechnology fields because of their smaller size and other unique properties. They can pass the blood−brain barrier and also can cross the cell boundaries in some cases. These can be used for the diagnosis of a particular disease at earlier stages and hence help in timely treatment. Quantum dots are also

used in targeted drug delivery so that a drug can be supplied to a specific organ or location and as a result, the healthy cells or other parts are not affected adversely. This will increase the efficacy of that drug. They have a bright future in combating dreadful diseases like cancer. They are also effectively utilized in biolabeling and bioimaging processes.

1.6 Conclusion

Quantum dots have certain unique features, such as large surface area-to-volume ratio, quantum confinement effect, and SPR. These make quantum dots quite interesting for possible application in a variety of fields. They are used as photocatalysts for degradation or the removal of a variety of environmental pollutants to smaller fragments, which are almost harmless, reduction of carbon dioxide curbing the ever increasing global warming, photosplitting of water generating hydrogen (the fuel of future), light emitting diodes (display, lighting, plant growth, improved crop production, night vision, antimicrobial activities), biolabeling, bioimaging, targeted drug delivery, solar cells, cancer therapy, sensing a particular compound in very low concentrations (ppm or even sometimes ppb also), etc. Quantum dots will find many more useful applications in the years to come.

Chapter 2

Hydrothermal synthesis of quantum dots

Jayesh P. Bhatt and Neha Godha
Department of Chemistry, PAHER University, Udaipur, Rajasthan, India

2.1 Introduction

The term "hydro" means water and "thermal" means heat. This word was first used by the British geologist Sir Roderick Murchison (1841). The action of water at high temperature and pressure has been considered responsible for changes in the Earth's crust, and it leads to the formation of various minerals and rocks. The first report on hydrothermal synthesis was of tiny quartz crystals by freshly precipitated silicic acid (Schafthaul, 1845). Now this term refers to any heterogeneous reaction that is carried out in the presence of aqueous solvents under high temperature and pressure conditions. Artificial diamond was also synthesized by Hannay (1880) using the hydrothermal method and Moissan (1893) also claimed to synthesize artificial diamond.

It is interesting to note that the hydrothermal method keeps a good control on composition and porosity. It is known that materials having high vapor pressure near this melting point normally form nanoparticles (NPs) by this method only. The solvothermal method is almost similar to the hydrothermal method but the only difference is in the wetting liquid, which is usually an organic solvent in place of water. The hydrothermal technique is used in a variety of fields, like chemistry, material science, biology, etc.

The hydrothermal conditions (high pressure and temperature) require a reaction vessel for crystal growth, which is called an autoclave. As some highly corrosive salts are used in the hydrothermal method to synthesize inorganic materials for a longer period reaction time, an autoclave must be able to sustain these highly corrosive materials at high pressure and temperature. The corrosion resistance is the most important property required in the material of the autoclave. Such corrosion-resistant

Quantum Dots. DOI: https://doi.org/10.1016/B978-0-12-824153-0.00002-1
© 2023 Elsevier Inc. All rights reserved.

materials include the following materials such as high-strength alloys, stainless steel, iron, titanium, nickel, and cobalt-based alloys. An autoclave is also coated inside with a non-reactive material to avoid corrosion; the most suitable material is Teflon (tetrafluoroethylene). As the Teflon has a larger coefficient of thermal expansion compared with the material enclosed within the liner, the coating of Teflon will expand and contract much more on heating and cooling than the reacting materials present inside the autoclave.

A good hydrothermal autoclave should have the following properties:

- It is inert to acids, bases, and oxidizing agents.
- It should be easy to assemble and dissemble.
- It should have a sufficient length to obtain a desired temperature gradient.
- It should be leakproof at desired temperature and pressure.
- It should bear high pressure and temperature for a longer duration of time.
- Reaction can be carried out under mild hydrothermal conditions of temperature less than 300°C and pressure 250 bars.

Parts of the Teflon-coated autoclave are presented in Fig. 2.1.

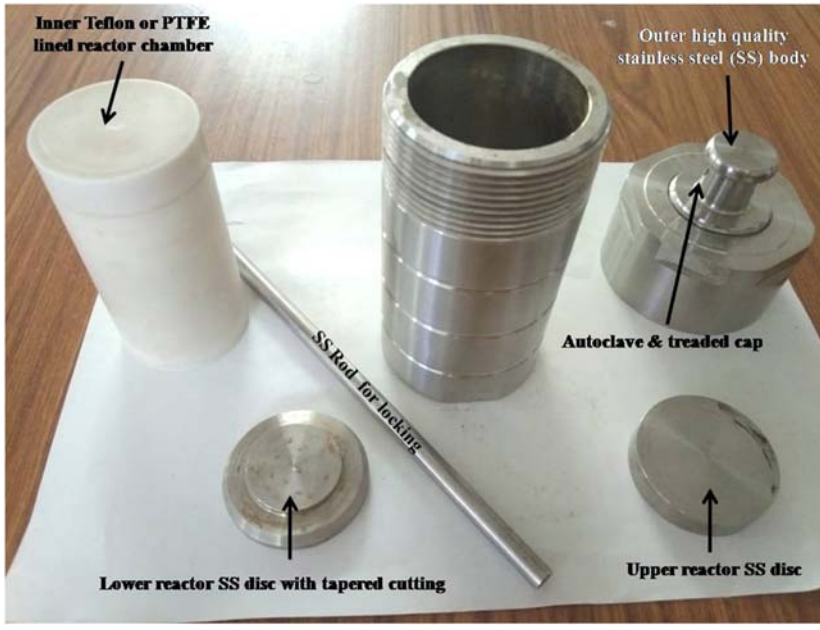

FIGURE 2.1 Teflon-lined autoclave reactor.

2.1.1 Advantages

The following are the advantages of hydrothermal synthesis:

- This method has the ability to create crystallize phases, particularly those that are not stable at the melting point.
- The material having high vapor pressure near its melting point can also be grown by this method.
- This method is suitable for the growth of large and good-quality crystals with a control on their composition.
- Relative cost is lower for this method compared with others.
- The hydrothermal method is more eco-friendly (green) than other methods of synthesis.
- It requires low temperatures, which avoids the problems encountered with high-temperature processes.
- It regulates the uniformity of nucleation, rate growth, aging, etc., which affect morphology, size, and aggregation. Various particle sizes and morphologies can be obtained with the hydrothermal method.
- Materials prepared by this method exhibit differences in point defects as compared with high-temperature synthesis. There are no Schottky defects in tungstates of Ca, Ba, and Sr prepared by this method, which are normally present in these compounds prepared at high temperatures.
- This method can be used in combination with other methods such as microwave, ultrasound, mechanochemistry, electrochemical, etc.

2.1.2 Disadvantages

- One of the major disadvantages of this method is that it needs expensive autoclaves.
- It is not possible to observe the crystal growing inside a steel tube.
- Now autoclaves made of thick-walled glass are used up to 300°C and 10 bar.
- The greatest disadvantages of Teflon lining is that beyond 300°C, it cannot be used because Teflon dissociates, which affects the pH of neutral solutions. This coating tends to get torn and generally must be replaced after experiments.

2.2 Metal-based quantum dots

2.2.1 Metal oxide quantum dots

A simple hydrothermal approach was used by Zhu et al. (2006) for synthesis of SnO_2 quantum dots. Here, hydrazine hydrate was used as the mineralizer and not the commonly used NaOH. The diameters of the SnO_2 NPs were determined to be in the range of 2.3−3.1 nm. A blueshift was observed of

0.28 eV and the bandgap of as-prepared SnO_2 QDs was found to be 3.88 eV. A biomolecule-assisted hydrothermal route was used by Wu et al. (2009) for generating SnO_2 QDs (diameters 10 nm). These were used for photocatalytic degradation of rhodamine B in a basic medium, where its degradation reached almost 100% within 150 min.

Wei et al. (2010) made use of WO_{3-x} QDs (nonstoichiometric) in combination with silver nanowires (Ag NWs) and reported that the incident photon-to-electron conversion efficiency (IPCE) can be increased by 8.5% and dye degradation improved by 40% with the sample $WO_{2.72}$ QD@Ag NW composite.

Perera et al. (2012) prepared TiO_2 nanotube (TNT)/reduced graphene oxide (rGO) composites using an alkaline hydrothermal process. They could achieve this by decorating graphene oxide (GO) layers on TiO_2 NPs. The TiO_2 NPs were found to be small in diameter ($\sim$9 nm). As-prepared composites were used for the photodegradation of malachite green. It was observed that composite with 10% rGO showed the highest photocatalytic activity, which was almost three times higher than pure TNTs.

The Mg-doped VO_2 NPs were synthesized by Zhou et al. (2013) via a hydrothermal method. It was reported that optical bandgap changed from 2.0 eV for pure VO_2 to 2.4 eV on 3.8% Mg doping. Yao et al. (2017) fabricated $CoFe_2O_4$ quantum dots/N-doped graphene ($CoFe_2O_4$ QDs/N-G) composites using the hydrothermal process followed by calcination at high temperatures. It was observed that NPs were homogeneously anchored on the surfaces of graphene sheets and the size of $CoFe_2O_4$ QDs was within 4−12 nm. It was reported that as-obtained $CoFe_2O_4$ QDs/N-G can be used as anode material for lithium-ion batteries (LIBs) with an initial discharge capacity of 1616 mAh g^{-1} maintaining a reversible capacity of 1223 mAh g^{-1} even after 90 cycles at a current of 100 mA g^{-1}.

Ma et al. (2017) observed the effects of N doping on the deposition of $ZnCo_2O_4$ QDs on rGO nanosheets. It was reported that as-prepared $ZnCo_2O_4$ QDs decorated on nitrogen-doped graphene (NG) were 4.3 ± 0.9 nm in diameter and were well-dispersed on the surface. It was indicated that as-obtained $ZnCo_2O_4$/NG hybrids can be used as a battery-type electrode for a hybrid supercapacitor and can deliver high specific capacity, outstanding rate capability, and excellent cycle performance of 301.8 C g^{-1} at 1 A g^{-1}, 84.5% remaining at 30 A g^{-1} and 89.1% after 5000 cycles, respectively.

Min et al. (2017) used a one-step hydrothermal route for preparing GQDs coupled with TiO_2 in the form of composite (TiO_2/GQDs) photocatalysts. They used 1,3,6-trinitropyrene (TNP) as the precursor of GQDs. Here, GQDs act as a photosensitizer as well as an excellent electron acceptor and this composite exhibited a seven times higher evolution rate of H_2. A highly efficient ternary photocatalytic nanocomposite, $ZnFe_2O_4/TiO_2$/CDs, was synthesized by Lu et al. (2018) through a hydrothermal method. This composite was used in the decomposition of rhodamine B. It was also revealed that it

retained its photocatalytic efficiency even after four cycles. A wide range of transition metal-doped TiO_2 (metal/TiO_2) (where M = Co, Ag, Cu, Au, Cr, Ni, Fe, Pt, Pd, and Zn) was prepared by Wu et al. (2018) combining the hydrothermal synthesis with air-thermal treatment. It was observed that 0.5 mol.%-Cu/TiO_2 NFs exhibited the highest photocatalytic activity in the production of hydrogen (208 $\mu mol^{-1}\ h^{-1}$).

SnO_2 QDs/TiO_2 NPs composite was prepared by Jat et al. (2019) via a hydrothermal method. They used stannic chloride (hydrate) as a precursor for SnO_2 quantum dots. It was observed that the photocatalytic activity of the composite was more than titania nanopowder for the degradation of fast green. The effects of various parameters like pH, the concentration of dye, amount of catalyst, and light intensity on the rate of degradation was also studied. It can be a promising method for wastewater treatment. A simple hydrothermal route was reported by Liu et al. (2019a,b) for the synthesis of tungsten oxide quantum dots (WO_{3-x} QDs). They used ammonium tungstate hydrate as a precursor and polyvinyl pyrrolidone. It was reported that this material is photochromic in nature and changes color in the presence of UV or sunlight.

2.2.2 Metal sulfide quantum dots

Zhao et al. (2009) selected thiol ligand, N-acetyl-l-cysteine as a stabilizer for the synthesis of high-quality NIR-emitting CdTe/CdS QDs by an hydrothermal route. It was reported that as-prepared NIR-emitting CdTe/CdS QDs exhibited high photoluminescence quantum yields (45% − 62%) and good photostability. It was also suggested that as-prepared QDs can be used for bioimaging as they have biological compatibility and excellent water solubility. Liu et al. (2012) synthesized water-soluble high-quality ternary $CuInS_2$ quantum dots via hydrothermal synthesis. They used mercaptopropionic acid (MPA) as the stabilizer. It was observed that it can be used to label liver cancer cells. It was also revealed that as-synthesized near-infrared (NIR) $CuInS_2$ QDs have excellent photostability.

The CdSeS quantum dots with diameter of 4.5 nm were prepared by Santra and Kamat (2013), which were highly luminescent. They observed maximum power conversion efficiencies of 3.2% and 3.0% in two- and three-layered tandem quantum dots solar cells, respectively. Liu et al. (2013) synthesized water-soluble $CuInS_2$ ternary quantum dots in aqueous solution, which was capped by MPA. The $CuInS_2$ QDs were covalently linked to 3-aminophenylboronic acid molecules to get functionalized $CuInS_2$ QDs (F-$CuInS_2$ QDs). These QDs were found to be reactive toward vicinal diols in alkaline solution to form five- or six- member cyclic esters.

Water-soluble Mn^{2+}-doped ZnS nanocrystals were synthesized by Zhang et al. (2014). These were surface capped with polyethylene glycol (PEG-ZnS:Mn^{2+}) in aqueous solution. It was reported that the size of particles had

an average diameter of 3 nm with a zinc blende structure. It was also revealed that as-obtained nanocrystals were water soluble and biocompatible. Han et al. (2014) prepared a ternary CdS/ZnO/graphene composite by loading ZnO and CdS NPs in graphene nanosheets using a one-step hydrothermal method. It was reported that as-prepared CdS/ZnO/graphene composite exhibited enhanced photocatalytic activity as compared to pure ZnO and CdS. It was attributed to the light absorption, efficient charge separation, and durability of the composite.

Uniform MoS_2 quantum dots were synthesized by Ren et al. (2015) via a hydrothermal route. It was reported that the as-prepared material has a monolayer thickness with an average size of 3.6 nm. A facile hydrothermal route has been also used by Wang and Ni (2014) for the synthesis of photoluminescent MoS_2 quantum dots. They used sodium molybdate and cysteine as precursors. As-prepared MoS_2 QDs were used to construct a sensor for the detection of 2,4,6-trinitrophenol (TNP) in a wide range of concentration from 0.099 to 36.5 μM with a high detection limit (95 nM). It was reported that this sensor can be applied for the detection of TNP in real samples.

Monolayer MoS_2 quantum dots with lateral size (3 nm) were prepared by Qiao et al. (2015). It was observed that the lateral size of the nanosheets decreases on increasing the number of exfoliations. It was reported that monolayer MoS_2 QDs exhibited higher hydrogen evolution reaction (HER) catalytic activities. Uniformly dispersed ZnS quantum dots (<10 nm) on graphene nanosheets were synthesized by Zhang et al. (2018) via a hydrothermal method. It was reported that as-prepared ZnS/graphene composites can be used as a dual anode for both LIB and sodium-ion batteries with excellent performance.

The Ag_2S/ Bi_4/Ti_3O_{12} heterojunction composite was prepared by Zhao et al. (2019). The Ag_2S quantum dots were assembled onto the surface of $Bi_4Ti_3O_{12}$ nanosheets. Its photocatalytic performance was evaluated for photocatalytic degradation of rhodamine B in aqueous solution under simulated sunlight. It was found that 15 wt.% Ag_2S $Bi_4Ti_3O_{12}$ composite exhibited the highest photocatalytic activity, which was about 2.8 and 4.0 times higher than that of pure $Bi_4Ti_3O_{12}$ and Ag_2S, respectively. This enhanced activity was explained on the basis of Z-scheme electron transfer from $Bi_4Ti_3O_{12}$ (conduction band) to Ag_2S (valence band).

Zeng et al. (2019) synthesized flower-like $MoS_2/Ag_2S/Ag$ nanocomposites. It was reported that as-prepared $MoS_2/Ag_2S/Ag$ nanocomposites can be used as photocatalysts for the photodegradation of tetracycline hydrochloride and Congo red and also for the disinfection of *P. aeruginosa*. It was verified that the electron transport path is a Z-scheme system. A one-step hydrothermal approach was reported by Li et al. (2019) to synthesize water-dispersed MoS_2 quantum dots. These QDs have an ultrasmall size of ~ 3.3 nm. These were loaded on CdS nanorods and then they exhibited an enhanced HER under visible light ($\lambda > 420$ nm) (131.7 mmol h^{-1} g^{-1}), which is about 65-fold the rate of pure CdS (2.0 mmol h^{-1} g^{-1}).

2.2.3 Others

A simple hydrothermal method was developed by Wang and Han (2010) for the synthesis of water-soluble, and NIR-emitting type core−shell CdTe/CdSe quantum dots. They used $CdCl_2$ and Na_2SeO_3 and thiol-capped CdTe QDs as core templates for this purpose. It was revealed that as-prepared CdTe/CdSe QDs showed excellent photostability, good monodispersity, and hardened lattice structure which has a great potential for different biological applications.

A high-performance supercapacitor cathode electrode was developed by Xia et al. (2015). It was composed of well-dispersed $MnCO_3$ quantum dots ($\sim$1.2 nm) decorated on nickel hydrogen carbonate−manganese carbonate ($Ni(HCO_3)_2$−$MnCO_3$). It was reported that as-prepared $MnCO_3$ QDs/NiH−Mn−CO_3 composites exhibited superior supercapacitive performance, which makes them potential cathode materials to be used in high energy density asymmetric supercapacitors.

2.3 Nonmetal-based quantum dots

2.3.1 Carbon-based quantum dots

Yu et al. (2012) prepared ZnO/carbon quantum dots (ZnO/CQDs) nanocomposites by hydrothermal reaction. It was reported that as-obtained photocatalyst can be used for the degradation of toxic gas (methanol and benzene) under visible light exhibiting higher photocatalytic activity (80%, 24 h) as compared to N-doped TiO_2 and ZnO NPs. A simple one-step hydrothermal method was developed by Guo et al. (2013) for the synthesis of highly fluorescent carbon NPs (F-CNPs). It was reported that these F-CNPs exhibited excellent probe ability for the detection of mercury ions in aqueous solution with good sensitivity and selectivity.

Yu et al. (2014a,b) prepared CQDs/TiO_2 nanosheet composites by a simple low-temperature process. The photocatalytic activity of this composite was observed for the degradation of rhodamine B in the presence of visible light irradiation. CQDs modified TiO_2P25 composites (CQDs/P25) were prepared by Yu et al. (2014a,b) via hydrothermal reaction. This composite exhibited enhanced photocatalytic H_2 evolution in the presence of visible light and UV without using any noble metal cocatalyst. Here, CQDs played dual roles for improving photocatalytic activity as they act as an electron reservoir as well as for efficient separation of the electron−hole pairs.

Zhang and Chen (2014) used a hydrothermal route to prepare highly luminescent nitrogen-doped CQDs (NCQDs). They used folic acid as the source of both carbon and nitrogen. It was reported that as-prepared NCQDs have an average size of 4.5 ± 1.0 nm. It was reported that an effective quenching effect of Hg^{2+} ions was achieved, and NCQDs can detect Hg^{2+} ions with a detection limit of 0.23 μM. This type of ions sensor was

successfully applied for the determination of Hg^{2+} in real samples such as tapwater and lake water. A facile method to synthesize stable CDs was reported by Wang et al. (2015) via hydrothermal treatment using glucose in the presence of glutathione. It was reported that as-prepared CDs can be used as pH sensors. Wei et al. (2016) prepared a series of carbon dots (CDs)/$NiCo_2O_4$ composites, It was observed that these samples have good electrical conductivities and exhibited high specific capacitances, cycling stabilities, and superior rate performance. It was revealed that this hybrid supercapacitor exhibited a high energy density up to 62.0 Wh kg^{-1}.

Martins et al. (2016) prepared a new composite of TiO_2 (P25) and N-doped CQDs (P25/NCQD) via a hydrothermal method. It was then used as a catalyst for the photooxidation of NO in the presence of UV and visible light. It was reported that as-prepared P25/NCQD composite exhibited NO conversion (27.0%), which was almost 2.7 times that of P25 (10%). It was also revealed that photodegradation of methylene blue was increased from 68% to 91% on UV irradiation.

Qian et al. (2016) incorporated CQDs with Bi_2WO_6. Then these were used for photocatalytic removal of gaseous volatile organic compounds in the presence of sunlight. It was revealed that CQDs/ Bi_2WO_6 exhibited higher photocatalytic oxidation in degrading toluene and acetone under both UV and visible light.

Wu et al. (2017) synthesized NCQDs by a hydrothermal method. They used microcrystalline cellulose as a source of carbon and ethylenediamine as a nitrogen dopant. It was reported that as-obtained NCQDs particles were spherical with an average diameter of 3.2 nm. When these NCQDs were used as a fluorescent probe for the detection of Fe^{3+} via fluorescent quenching, then they could achieve high sensitivity and selectivity with a limit of detection of 0.21 nM.

A ternary composite of GO/CD/polypyrrole (GO/CDs/PPy) was prepared by Zhang et al. (2017) and then used as an electrode active material for supercapacitors. It was reported that CDs sandwiched between PPy and GO film layer can promote electron transportation in such composites and as a result, charge transfer resistance of the electrode and internal resistance are reduced. It was interesting to note that it retained excellent cycle stability even after 5000 cycles. Liu et al. (2017) monitored the effect of arginine (Arg) on the growth of gold NPs/CQDs (Au/CQDs) composite. Ethylene glycol was used as the reducing as well as stabilizing agent for the preparation of CQDs. The arginine can be detected with a low detection limit of 37 nM using this nanocomposite based on the color change.

A three-dimensional (3D) ternary graphene-CQDs/g-C_3N_4 nanosheet (GA-CQDs/CNN) aerogel was synthesized by He et al. (2018) via a hydrothermal method. It was reported that this ternary photocatalyst could improve the absorption of visible light as well as promote separation of charges. It was observed that methyl orange can be removed up to 91.1% using

GA-CQDs/CNN-24%, which was about 7.6 times more than that with bulk g-C_3N_4 (BCN).

Zhao et al. (2018) synthesized nitrogen-doped CQDs via a hydrothermal method. They used polyacrylamide as both the carbon and nitrogen source. It was reported that as-prepared NCQDs could be used as effective probes for selective and sensitive detection of dopamine with a detection limit of 0.05 μM in the concentration range of 0.1−200 μM. The proposed method was also applied for determination of dopamine in urine samples. Wang et al. (2018) reported a novel ternary photocatalyst, which comprised single atom-dispersed silver and CQDs coloaded with ultrathin g-C_3N_4 (SDAg-CQDs/UCN). It was then used for photocatalytic degradation of naproxen, which involved hydroxylation, decarboxylation, and opening of the naphthalene ring.

Liu et al. (2019a,b) prepared nitrogen and boron codoped CQDs (NB-CQDS) via a one-pot hydrothermal treatment. They used citric acid, borax, and *p*-phenylenediamine for this purpose as the source of carbon, boron, and nitrogen, respectively. It was revealed that NB-CQDs were almost monodispersed with an average particle diameter of 3.53 nm. A sensor was designed using NB-CQDs for the determination of acetone and dopamine with a limit of detection of 0.54 μM and 11 nM, respectively. Aziz et al. (2019) prepared CQDs using branched polyethyleneimine to modify these dots. It was observed that fluorescence of CDs could be efficiently quenched by mercuric ions in aqueous solution. It was revealed that this probe can be used for the detection of Hg^{2+} ions in the concentration range from 20 to 800 nM with a detection limit of 10.0 nM. It provides a simple, selective, and sensitive fluorescence probe for Hg^{2+}.

Wang et al. (2019) used biomass of cyanobacteria as a carbon source for synthesizing fluorescent and water-soluble CQDs via a hydrothermal method. It was reported that as-synthesized CQDs were found to be monodispersed with an average diameter of 2.48 nm. It was observed that as-prepared CQDs exhibited high photostability with no photobleaching, even if kept for a longer time under UV irradiation. One advantage of such CQDs is that they could illuminate the complete cell and differentiate the cytoplasm from nucleus. It was also proposed that biomass of cyanobacteria can be used to fabricate CQDs on a large scale.

Water-soluble highly green fluorescent CQDs were prepared by Dhandapani et al. (2020) via hydrothermal carbonization of cost-effective wastes of fish. It was reported that the as-synthesized sample exhibited photoluminescence with high green emission 406 at the excitation of 330 nm. The UV−Vis spectra showed the presence of two major peaks at 266 and 371, due to $\pi \rightarrow \pi^*$ and $n \rightarrow \pi^*$ transition, respectively. It was revealed that as-prepared CQDs are spherical in shape with size $\sim 6 \pm 1$ nm. It was suggested that as-synthesized CQDs may be used for water treatment and energy application.

Guo and Zhao (2020) synthesized blue emissive NCQDs via the hydrothermal treatment with a high quantum yield as high as 84.79%. They used diethylenetriamine and citric acid as a source of nitrogen and carbon, respectively. It was reported that as-prepared NCQDs exhibited good photostability, and excellent stability in high-salt conditions. It was revealed that as-prepared NCQDs can be used as potential probes for detecting ellagic acid selectively in a concentration range of 0.01−50 μM on the basis of the inner filter effect. It was suggested that there is good biocompatibility of the NCQDs, which indicates that it has a great potential for application in biomedical fields.

Khan et al. (2020) synthesized nitrogen and sulfur codoped water-soluble CQDs (NS-CQDs) via a hydrothermal route. They used L-lysine and thiourea for this purpose. It was reported that as-obtained NS-CQDs have a high quantum yield of 53.19 % with a blue fluorescence on excitation UV light (365 nm). It was revealed that NS-CQDs were spherical in shape with sizes in the range 5−8 nm (average diameter 6.86 nm). It was observed that NS-CQDs can act as a fluorescent probe for the sensitive and selective detection of picric acid in aqueous solution in the concentration range of 1−10 μM with a limit of detection as 0.24 μM. It was reported that these NS-CQDs fluorescent probes can be used to measure the concentration of picric acid in a real water sample of tapwater.

Wei et al. (2020) synthesized boron and nitrogen codoped CQDs (BNCQDs) via a microwave-assisted hydrothermal method. They used boric acid and o-phenylenediamine as the sources of boron, carbon, and nitrogen. It was reported that as-prepared BNCQDs exhibited high QY (13.79%), good biocompatibility, fluorescent stability, and low toxicity, which are necessary requirements for a cell imaging agent. It was revealed that accumulation was increased with an extension of incubation time with HeLa cells, and it was observed that BNCQDs imaging is suitable for cell morphology (Fig. 2.2).

Li et al. (2020) obtained two types of CQDs via a hydrothermal method. These CQDs had luminous peaks at 480 (blue CDs) and 525 nm (green quantum dots). These two QDs were used for the detection of Hg^{2+} ions. It was

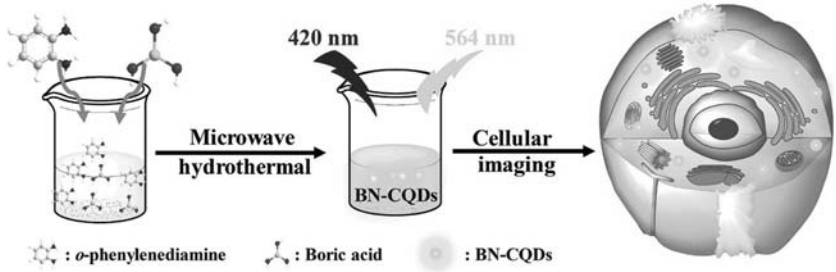

FIGURE 2.2 Synthesis of B, N-doped carbon quantum dots and their use in cellular imaging. *Adapted from Wei, Y., Chen, L., Wang, J., Liu, X., Yang, Y., Yu, S., 2020. Rapid synthesis of BN co-doped yellow emissive carbon quantum dots for cellular imaging. Optical Mater. 100. https://doi.org/10.1016/j.optmat.2019.109647. With Permission.*

observed that mixed CDs could detect Hg^{2+} ions in the range of 0−1.0 μM with a low detection limit of 0.05 μM.

Shahba and Sabet (2020) synthesized highly photoluminescence carbon nanofibers/CQDs using pine fruit via a ball milling-assisted hydrothermal method. It was revealed that the as-obtained product was composed of carbon nanofibers and very tiny nitrogen-doped CDs with a high photoluminescence intensity. The photocatalytic activity of as-prepared material was investigated by degradation of six different dyes (methyl orange, erichrome black T, acid blue, eosin Y, methylene blue, and methyl). It was also reported that it can adsorb Cd^{2+} and Pb^{2+} ions from the water with almost 100% efficiency.

Wang et al. (2020) prepared biomass CQDs via a hydrothermal process. They used four biomass wastes as a source of carbon (magnolia flower, orange peel, paulownia leaves and ginkgo biloba leaves). The as-prepared biomass CQDs exhibited homogeneous particle size, optical properties, stability, and superior water solubility. A quenching effect on fluorescence was observed on the addition of Fe^{3+} ions into CQDs solution. It was reported that as-prepared CQDs have a sensitive response to Fe^{3+} ions and these ions can be measured in the concentration range of 0.2 − 100 μM with the limit of detection of 0.073 μM (Fig. 2.3).

Sharma et al. (2020) synthesized fluorescent CQDs via a hydrothermal approach using red cabbage (rc). It was reported that as-synthesized rcCQDs were having an average size of 3 nm with blue fluorescence and quantum yield of 8.3%. It was interesting to note that rcCQDs exhibited strong antioxidant activities of 56%, 61%, and 91% against hydroxyl,2,2-diphenyl-1-picrylhydrazyl, and potassium permanganate radicals, respectively, which was almost comparable with that of L-ascorbic acid (standard antioxidant). A superior biocompatibility and negligible cytotoxicity of as-synthesized rcCQDs on SH-SY5Y neuroblastoma cells was there as evident from Cell Counting Kit−8 assay. These rcCQDs were also used as a fluorescent probe for biolabeling of *Staphylococcus aureus* and *Escherichia coli*. These rcCQDs can also be utilized as a fluorescent ink, and may found to be suitable for varnish and paints.

Chaudhary et al. (2020) synthesized highly fluorescent NS-CQDs via hydrothermal process. They used banana (*Musa acuminata*) juice as the source of carbon. It was revealed that NS-CQDs were spherical shaped with an average size of 1.27 nm, but with poor crystallinity. The proposed method

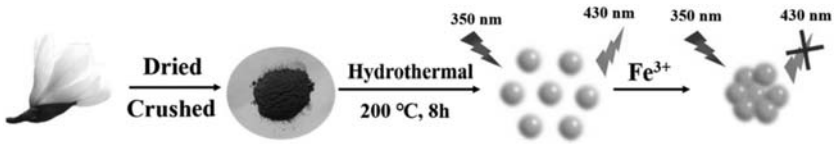

FIGURE 2.3 Preparation of quantum dots from biomass waste and detection of ferric ions. *Adapted from Wang, C., Shi, H., Yang, M., Yan, Y., Liu, E., Ji, Z., et al., 2020. Facile synthesis of novel carbon quantum dots from biomass waste for highly sensitive detection of iron ions. Mater. Res. Bull. 124, https://doi.org/10.1016/j.materresbull.2019.110730. With Permission.*

offers higher quantum yield (32%) compared to samples prepared from other natural sources. It was reported that as-synthesized NS-CQDs can be utilized as a fluorescent probe for the detection of Cu(II) in the concentration range of 1−800 μg mL^{-1} with the LOD of 0.3 μg mL^{-1} in the water sample.

2.3.2 Graphene-based quantum dots

Shen et al. (2012) prepared graphene quantum dots (GQDs) by a one-pot hydrothermal reaction. They used polyethylene glycol (PEG) and small GO sheet as the starting materials. It was reported that as-prepared GQDs-PEG exhibited luminescence properties. Tang et al. (2012) prepared crystalline GQDs that were water soluble. Glucose was used as the source of carbon. As-prepared QDs have an average diameter as small as 1.65 nm. A microwave-assisted hydrothermal method was used for this purpose. It was revealed that as-prepared GQDs can convert blue light into white light, when these GQDs were coated onto a blue light-emitting diode.

Wang et al. (2014) synthesized stable blue fluorescent GQDs via a hydrothermal method. The fluorescence of reoxidized grapheme oxide was quenched by Cu(II) in water. It can be used as a fluorescence sensor for the detection of cupric ions with high selectivity and sensitivity as compared to other metal ions in concentration range of 0−15 μM with a detection limit of 0.226 μM.

Qu et al. (2014) synthesized a series of GQDs via a hydrothermal process. They used citric acid as a carbon precursor and formed an N-free GQD graphite framework. It was reported that N-doped GQDs were prepared using urea. It was reported that the pyrrolic N was transformed to graphite N under these conditions. It was reported that the highest photoluminescence quantum yield PL QY (94%) of N-doped GQDs could be achieved using ethylenediamine as an N source.

Wu et al. (2014) reported the preparation of dicyandiamide (DCD) N-doped high quantum yield GQDs via a hydrothermal method. They used citric acid as the source of carbon. It was observed that N-doping of GQDs can promote a photoluminescence quantum yield (36.5%). It was also revealed that as-obtained N-doped GQDs were pH-sensitive, photostable, and had low toxicity, and therefore can be used as a pH sensor in a wide range from real water to intracellular contents. Ju and Chen (2014) prepared nitrogen-doped GQDs via hydrothermal treatment, a simple and low-cost approach. They used hydrazine as the source of nitrogen. Due to the selective coordination to Fe^{3+}, as-prepared N-GQDs can be used for selective detection of Fe(III) ions in aqueous solution as well as real water samples with a detection limit of 90 nM.

Fei et al. (2014) synthesized GQDs from anthracite coal, and then self-assembly on graphene by hydrothermal treatment. They observed the formation of hybrid nanoplatelets which were then codoped with nitrogen and boron. It was reported that as-prepared composite exhibited excellent oxygen

reduction reaction (ORR) electrocatalysis with higher activity as compared to commercial Pt/C in alkaline media. Lee et al. (2015) synthesized graphene-decorated V_2O_5 nanobelts (GVNBs) via a hydrothermal method. The GVNBs composite with (VO/GO = 3:1) exhibited excellent specific capacitance as compared to other composites and pure materials. This composite also showed excellent cyclic stability and retention of capacitance (82%) even after 5000 cycles.

Permatasari et al. (2016) synthesized GQDs containing N atoms via a hydrothermal method. They used urea and citric acid as the starting materials. It was revealed that as-prepared GQDs were spherical in shape with an average diameter of 2.17 nm. Fan et al. (2017) functionalized covalently arylamine-based polyazomethine with functionalized GO quantum dots (TPAPAM-GOQDs). It was prepared by an amidation reaction to design a ternary memory device with a configuration of gold/TPAPAM-GOQDs/indium tin oxide. It was claimed that this memory device could enhance the memory capacity of a device from the conventional 2^n to 3^n as compared to binary memory devices.

The composites of N, S codoped GQDs (N, S-GQDs)-rGO-TiO_2 nanotubes (TiO_2NT) were prepared by Tian et al. (2017) via alkaline hydrothermal reaction. It was reported that as-prepared N, S-GQDs/10%rGO/TNT composite exhibited the highest photodegradation efficiency for the degradation of methyl orange, which was 1.8 times and 16.3 times more than 10% rGO + TNT and pure TNT, respectively.

Yao et al. (2018) prepared in situ sulfur-doped GQDs via a hydrothermal method, which were decorated with CNPs to give (S-GQDs/CNPs) hybrid. It was reported that S-GQDs were decorated on CNPs by $\pi-\pi$ stacking. In this case, the advantages of both GQDs as well as CNPs are combined, which will facilitate the electron transfer between S-GQDs and CNPs. It was indicated that the layer by layer modified method in the S-GQDs/CNPs hybrid can inhibit the two-electron pathway and cause a four-electron pathway for ORR rate. It was revealed that the as-prepared S-GQDs/CNPs hybrid exhibited a better methanol tolerance along with long-term durability as compared to commercial 20% Pt/C.

A ternary nanocomposite of high fluorescent polyaniline (PANI)/2-acrylamido-2-methylpropanesulfonic acid (AMPSA) capped silver NPs/GO quantum dots (PANI/Ag (AMPSA)/GO QDs) was synthesized by Shokry et al. (2019) via in situ oxidative polymerization of aniline in the presence of Ag (AMPSA) NPs and GO QDs. The Ag(AMPSA) NPs and GO QDs were prepared by reduction by silver nitrate and carbonization of glucose methods, respectively.

GQDs were synthesized by Hoang et al. (2020) from GO via a microwave-assisted hydrothermal method. This proposed method requires a relatively shorter time (10 min.) as compared to conventional hydrothermal routes. It was reported that as-prepared NPs have a diameter of about

2–8 nm. There was a blue emission on exposure to UV irradiation. It was observed that as-synthesized GQDs can be utilized as a hole transport layer in organic solar cells and quantum efficiency of the cell was increased. It was revealed that on mixing P3HT:PCBM polymer and GQDs, potential difference was reduced at the interfaces of the two materials. It was observed that the overall efficiency of the cell was enhanced by 1.43%, which was about a 44% increase compared to pristine cells (0.99%).

2.4 Recent developments

Although hydrothermal synthesis has been used for a long time with good results, there are some recent developments in this direction. Some of these advancements are summarized in Table 2.1.

TABLE 2.1 Synthesis of quantum dots by hydrothermal route.

Source	Application	References
Carbon quantum dots	Fluorescent (emission range 280–420 nm), a highly sensitive and selective probes for detection of Fe^{3+} ions	Latief et al. (2021)

Carbon quantum dots	In vivo bioimaging	Atchudan et al. (2021)
Carbon quantum dots	Sensitivity and detection of highly toxic chromium(VI) ions	Baragau et al. (2021a,b)
N-doped carbon quantum dots	Ion detection and cell imaging	Shen et al. (2021)
Carbon quantum dots	Oil recovery	Baragau et al. (2021a,b)
Carbon quantum dots/ silver nanoparticles	Determination of losartan potassium (pure form and pharmaceutical formulations)	Abdoon and Atawy (2021)

2.5 Conclusion

Various nanomaterials or quantum dots can be easily prepared by the hydrothermal approach. This method has the advantages of a good control on the size of the particle and their morphology. It requires relatively low temperatures, thus avoiding the problems encountered with high-temperature processes. The materials having high vapor pressure near their melting points can also be synthesized using this technique. Apart from this, the hydrothermal method can also be used in combination with some other approaches, such as microwave-assisted, ultrasound-assisted, etc., to give good yields of the desired products with high purity.

Chapter 3

Sol–gel synthesis of quantum dots

Avinash K. Rai[1] **and Kanchan K. Jat**[2]
[1]*Department of Chemistry, PAHER University Udaipur, Rajasthan, India,* [2]*Department of Chemistry, M. L. S. University Udaipur, Rajasthan, India*

3.1 Introduction

The sol–gel process is a new approach to the preparation of nanomaterials. A sol is a stable dispersion of colloidal particles or polymers in a solvent. It allows a better control in the synthesis of solids. It is a wet-chemical technique used for the preparation of both glassy as well as ceramic materials. The sol–gel process is based on hydrolysis and polycondensation reactions. During this process, first the sol (or solution) is evolved, which gradually proceeds to the formation of a gel-like network containing both a liquid phase and a solid phase. The basic structure (morphology) of the solid phase can have a wide range, starting from discrete colloidal particles to chain-like polymer networks. Synthesis using a sol–gel approach is used in the preparation of ceramic materials such as metal oxides, nitrides, and carbides. It results in the formation of a sol, which turns into a gel after a series of chemical reactions and/or mild thermal treatments. It is finally calcined to obtain the desired product.

- The basic idea behind sol–gel synthesis is to first dissolve the compound in a liquid and then bring it back as a solid; of course in a controlled manner.
- This technique provides facile preparation of compounds by mixing sols of different compounds.
- It avoids problems encountered in coprecipitation methods and gives smaller particles.

Sol–gel is a method for preparing metal oxide glasses, ceramics, etc. First, a chemical precursor or their mixtures are hydrolyzed, forming a solution state, which is converted to a gel state and then it is dehydrated to a ceramic or glass (Fig. 3.1).

Quantum Dots. DOI: https://doi.org/10.1016/B978-0-12-824153-0.00003-3
© 2023 Elsevier Inc. All rights reserved.

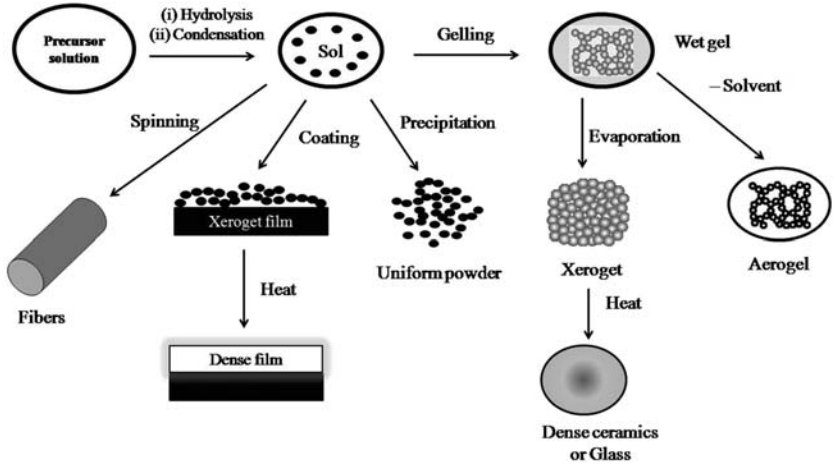

FIGURE 3.1 Different steps involved in sol–gel and related processes.

This technology can be used to prepare thin films, fibers, microspheres, fine powders, etc. It can be used to obtain catalysts, protective coatings, piezoelectric devices, lenses, wave-guides, superconductors, high-strength ceramics, insulating materials, nanoparticles (quantum dots also) etc.

Basically, it involves three steps:

- firstly, partial hydrolysis of metal alkoxides to form reactive monomers;
- condensation of as-prepared monomers to form colloid-like oligomers, known as sol formation; and
- additional hydrolysis leading to polymerization and cross-linking for a gel formation (three-dimensional matrix).

The various steps involved in sol–gel process are:

1. hydrolysis and condensation of compounds (sol formation);
2. gelation (sol–gel transformation);
3. aging; and
4. drying.

In the first step, a sol is formed, which is a stable dispersion of colloidal particles (it may be crystalline or amorphous) or polymers in a solvent. Then gel is formed by a three-dimensional (3D) continuous network, which contains a liquid phase, or by polymer chains. Some agglomerates of colloidal particles are there while the particles have some polymeric aggregates of subcolloidal particles in a polymer gel.

During this process, the solvent is trapped inside the gel as viscosity rapidly increases. Its structure may change considerably with time, depending on temperature, solvent, and pH. The liquid phase still contains agglomerates

and sol particles, which react there and condense on drying of the gel. Originally, the gel is flexible, but on condensation, it becomes more viscous. This will squeeze out the liquid present in the interior of the gel, and shrink it until there is a flexibility in the gel.

3.1.1 Advantages

The following are the advantages of this process:

- It provides a better control of the structure, such as particle size and porosity.
- It provides possibility of incorporating nanosized materials.
- It can ensures an excellent adhesion between top layers and substrate by forming thin coating.
- Relatively high purity is retained.
- It provides a good control on composition.
- It can be carried out at a relatively low temperature.
- There is no need for special or expensive equipment.

3.1.2 Disadvantages

There are some disadvantages of this process also and these are:

- There is long processing time.
- Organic solvents are used, some of which may be toxic.

3.2 Synthesis of quantum dots

3.2.1 Oxides

Lin et al. (2005) synthesized ZnO quantum dots via a simple sol–gel method. It was reported that the average size of these quantum dots can be tailored by variation of the concentration of the precursor of zinc. Size-dependent blueshifts of photoluminescence and absorption spectra revealed the quantum confinement effect. The ZnSe quantum dots were embedded in SiO_2 thin films by Jiang et al. (2004) via a sol–gel process. They used Zn $(Ac)_2 \cdot H_2O$ and H_2SeO_4 as the source of zinc and selenium, respectively. It was indicated that the size of the crystallite was increased with the concentration of selenium.

Li and Qu (2007) prepared CdTe quantum dots-derived composite with silica spheres coated with 5,11,17,23-tetra-*tert*-butyl-25,27-diethoxy-26,28-dihydroxycalix[4]arene (C[4]/SiO_2/CdTe) via a sol − gel approach. It was observed that FL intensity was increased linearly with increasing methomyl (pesticide) concentration (0.1 − 50 μM) with a limit of detection of 0.08 μM. On the other hand, it was negligible as compared to other pesticides, such as

parathion-methyl, fenamithion, acetamiprid, and optunal. Bera et al. (2008) reported synthesis and spectroscopic characterization of sol−gel derived zinc oxide quantum dots of 3−8 nm size. The quantum dots exhibited a broad and strong visible emission peak centered near 520 nm with a quantum efficiency of approximately 5%.

Zhang et al. (2010a) synthesized ZnO quantum dots via a sol − gel route. They used a zinc − oleate complex as a precursor. It was reported that as-obtained ZnO QDs had diameters in the range of 2.2 − 7.8 nm. It was revealed that ionized oxygen vacancies are responsible for the origin and intensity of the visible emission of ZnO QDs, while the visible emission peak position of ZnO QDs is decided by the following two factors:

- size; and
- transition of holes from the valence band to preexisting deep donor energy level.

The ZnO quantum dots were synthesized using the same precursors (Zhang et al., 2010b). It was reported that as-obtained ZnO QDs hexagonal had a wurtzite structure with particle size diameter of 8.9 nm. It was revealed that there is a redshift excitation. It was also observed that visible emission also shifted to the green luminescence band from yellow on increasing the annealing temperature.

Yu et al. (2010) synthesized Eu^{3+}-doped glass ceramics embedded ZnO quantum dots via a sol−gel method. It was revealed that ZnO QDs obtained were in the range of 3−6 nm. It was reported that these glass ceramics had a high transparency in the visible−infrared range, which may be due to the much smaller size of the ZnO QDs as compared to the wavelength of the visible light. CdTe quantum dots-doped TiO_2 photocatalysts were synthesized by Li et al. (2010) via a facile sol−gel method at room temperature. The photocatalytic activities of the as-prepared sample were investigated for the degradation of malachite green. It was found that the sample doped with 0.06 wt.% CdTe QDs exhibited the highest photocatalytic activity.

Chen et al. (2011) also synthesized ZnO quantum dots by a sol−gel method. These QDs exhibited a strong blue emission. It has been reported that ZnO QDs had an average diameter of 16.0−32.2 nm. It was observed that a higher reaction temperature and longer reaction time resulted in larger average size for QDs. It was revealed that a reduction in photoluminescence and increase of the size of ZnO QDs were similar for annealing in nitrogen, vacuum, and air.

Zinc oxide quantum dots with blue emission were synthesized by Han et al. (2012) via a sol−gel method. It was interesting to note that the blue emission was neither due to quantum confinement nor intermediate products. It was achieved only in the presence of Li^+ cations and hydroxide ions. It was revealed that an excess of OH^- ions is responsible for the formation of interstitial oxygen defects, while Li^+ ions can stabilize these defects by

substituting Zn atoms causing a blueshift of the blue emission. The Cd-doped ZnO quantum dots were prepared by Zhang et al. (2012) through a sol−gel method. The effect of Cd concentration and mass ratio of trioctylphosphine oxide (TOPO)/octadecylamine (ODA) on structural and luminescent properties of QDs was also evaluated. It was reported that Cd-doped ZnO QDs are 3−6 nm in diameter. It was observed that QD particle size was found to be reduced on increasing the Cd content. It was revealed that UV and fluorescence spectra both were blueshifted. The best optical performance was achieved when the TOPO/ODA mass ratio was kept 1:2.

The lanthanum-doped ZnO quantum dots were synthesized by Sun et al. (2012) via a modified sol−gel method. It was reported that La-doped quantum dots exhibited enhanced luminescent properties and their quantum yield was 77.9%. Then they prepared anticounterfeiting inks by incorporating these La-doped ZnO QDs into the transparent oil. The sol−gel method was applied by Korala et al. (2013) to fabricate thin films of CdSe and core(shell) CdSe(ZnS) QDs. It was reported that more than twofold enhancement in photocurrent could be achieved with an increase in photovoltage due to passivation of surface defects via overcoating with a thin ZnS shell. As a result as-prepared QD thin films are considered suitable for a wide range of optoelectronic applications.

Ge et al. (2013) fabricated a composite of TiO_2 films with CdTe quantum dots. Different CdTe QDs (green-, yellow-, and red-emitting) were obtained, when thioglycolic acid was used as a capping agent. It was revealed that red-emitting CdTe QDs exhibited a small blueshift of 1 nm, while green-emitting QDs showed a blueshift of 7 nm. A nonhydrolytic sol−gel combustion method was used by Leelavathi et al. (2013) for synthesis of nanocomposites of PbO quantum dots on anatase TiO_2. It was indicated that the photocatalytic activity of quantum dot dispersed TiO_2 was higher than that of TiO_2 and much higher as compared to commercial Degussa P-25.

Zinc oxide quantum dots were synthesized by Kumar et al. (2014) via a simple sol−gel method. They used zinc acetate dehydrate, sodium hydroxide, and methanol as starting materials. A good crystallinity was observed in these QDs with average crystallite sizes $\sim$14 nm. It was suggested that as-synthesized ZnO QDs can be used as the electrode material for dye-sensitized solar cells. Li et al. (2014) synthesized Pr^{3+}-doped semiconductor ZnO quantum dots via a sol−gel method. It was reported that as-obtained ZnO QDs were spherical in shape and the diameter was around 5 nm. It was revealed that emission peaks of aged ZnO QDs exhibited a redshift due to the increasing size of the QDs.

Zhong et al. (2014) synthesized $CuGaS_2$ quantum dots, which were embedded in sodium borosilicate glass matrix by combining two processes: sol−gel and heat treatment in H_2S gas. It was observed that as-obtained $CuGaS_2$ quantum dots had a spherical shape and were uniformly distributed with sizes ranging from 5−25 nm. The formation of stable colloids

containing surface-modified ZnO QDs was reported by Moghaddam et al. (2015) via a sol−gel process in an ultrasonic bath. They used 3-aminopropyltriethoxysilane (APTES) as a capping agent. Alcoholic solutions of zinc acetate and potassium hydroxide were used as the reactants. The formation of nanocrystals of ZnO QDs with average size of ∼3 nm was confirmed. It was suggested that the as-prepared ZnO QDs were found to be suitable for optical and optoelectronic applications.

Liu et al. (2015) synthesized ZnO quantum dots by a sol−gel method. They used (methanol, ethanol, or hexanol) as solvents. It was indicated that as-prepared ZnO QDs were having good dispersion and their size ranged from 3.3−7.7 nm, which could be controlled by variation of the solvents. It was revealed that ZnO QDs exhibited visible emissions ranging from green to orange. Bajaj and Omanwar (2015) synthesized α-Al_2O_3 quantum dots by the stearic acid sol−gel synthesis. The as-prepared sample exhibited good UV absorption and blue emission at 254 and 403 nm, respectively. Gnanasekaran et al. (2015) synthesized TiO_2 quantum dots by the sol−gel method. It was reported that TiO_2 QDs have a pure anatase phase with a tetragonal structure. The photocatalytic activity of TiO_2 QDs have been evaluated for the degradation of methylene blue and methyl orange under UV light irradiation.

The synthesis of TiO_2 quantum dots has been reported by Sood et al. (2015) via a simple sol−gel, template-free method. They also evaluated catalytic behavior of as-synthesized quantum dots by photocatalytic degradation of Indigo carmine dye in the presence of UV light. Chen et al. (2016) synthesized TiO_2 and carbon quantum dots-doped TiO_2 nanocomposite (CQDs/TiO_2 nanocomposite) by a sol−gel approach. They evaluated the photocatalytic activity of TiO_2 and CQDs/TiO_2 composite for the degradation of rhodamine B and cefradine. It was observed that the photocatalytic activity of CQDs/TiO_2 was higher compared to TiO_2.

Miao et al. (2016) prepared visible light responsive carbon quantum dots embedded in mesoporous TiO_2 materials via a sol−gel process. The photocatalytic performance of as-prepared CQDs/meso-Ti-450 was investigated for the degradation of methylene blue. It was revealed that 5% CQDs/meso-Ti-450 can remove almost complete (98%) methylene blue, whereas commercial P25 can remove only 10% of the dye. The TiO_2 (mesoporous) with different concentration of CdS quantum dots was successfully fabricated by Zhou et al. (2017) via a sol−gel method. The photocatalytic activity of the as-prepared CdS/TiO_2 samples was evaluated for the degradation of methyl orange, and it followed the order:

$$2\%\ \mathrm{CdS/TiO_2} > 4\%\ \mathrm{CdS/TiO_2} > 8\%\ \mathrm{CdS/TiO_2} > \text{pure}\ \mathrm{TiO_2} > 1\%\ \mathrm{CdS/TiO_2}.$$

The 2% CdS/TiO_2 has also been used for the degradation of methylthionine chloride, malachite green, rhodamine B, and bisphenol A.

Soumya et al. (2018) synthesized Sn and Ag-doped ZnO quantum dots via a microwave-assisted sol−gel strategy. They used 3-aminopropyl trimethoxy silane as a capping agent. Then these ZQDs were dispersed in methyl methacrylate monomer and polymerized in situ to obtain PMMA/ZQDs. It was indicated that as-prepared doped ZQDs/PMMA hybrid coatings exhibited blue emission under UV light. It was revealed that undoped PMMA/ZQDs hybrid coatings showed only <14% NIR reflectance, which was enhanced by 30% and 23% on doping with Ag and Sn in PMMA/ZQDs hybrids, respectively. It was concluded that these ZQDs doped with Sn and Ag ions on treatment with dye and inorganic coactivators, can find applications in photochromic and UV/NIR shielding solar-control interface coatings.

Ye (2018) used a sol−gel method for the synthesis of stable ZnO QDs. They also observed the effects of reactants concentration, reaction time, and material ratio on particle sizes and defects structures of ZnO. The highest photoluminescence quantum yield (40%) with green emission was observed under UV light excitation (359 nm). Garcia et al. (2019) synthesized TiO_2 quantum dots by sol−gel process. They used ionic liquid (1-*n*-butyl-3-methylimidazolium tetrafluoroborate) as the stabilizing agent. An adhesive resin was formulated by mixing these QDs with methacrylate monomers. As-prepared adhesive resins were evaluated for antibacterial activity, cytotoxicity, polymerization behavior, fracture pattern, degree of conversion, and microtensile bond strength. It was reported that 26 wt.% of $BMI.BF_4$. TiO_2 QDs/$BMI.BF_4$ had a minimum size range of 1.19−7.11 nm, and an average size of 3.54 ± 1.08 nm.

A sol−gel reflux condensation route was developed by Javed et al. (2019) to produce TiO_2 QDs. They used titanium tetraisopropoxide as the precursor, which was first hydrolyzed and followed by reflux condensation for 24 h. It was revealed that as-prepared QDs were spherical in shape with an average crystallite size of 5−7 nm. The energy bandgap of TiO_2 QDs was found to be $\sim$3.76 eV. A series of ZnO quantum dots were prepared by Sowik et al. (2019) modified with rare-earth metals through a sol−gel approach. They selected Eu, Er, Tb, Yb, Ho, and La to modify ZnO QDs. It was observed that as-prepared modified ZnO QDs can degrade phenol in aqueous phase. The order of photocatalytic activity among all these as-obtained nanomaterials followed the order:

$$\mathrm{ZnO/0.09\ mm_Er} > \mathrm{ZnO/0.18\ mm_Eu} > \mathrm{ZnO/0.09\ mm_La} > \mathrm{ZnO/0.27\ mm_Er} > \mathrm{ZnO/0.18\ mm_Tb} > \mathrm{pristine\ ZnO\ QDs}.$$

The ZnO and Au textured ZnO-based quantum dot thin film was fabricated by Dey and Sarkar (2020) and used as sensors. The as-fabricated sensor had an operating temperature of 35°C and it could be used for detecting a minute fraction vapors of different alcohols such as methanol, ethanol, propanol, and butanol. An annealing treatment at 350°C temperature was

imposed to improve the response of as-prepared sensors. Mohamed et al. (2020) synthesized three samples of ZnO quantum dots using a modified sol−gel method. It was reported that the average crystallite size, bandgap energy, and active surface area were 7.1 nm, 3.49 eV, and 150.1 $m^2\ g^{-1}$) for a sample prepared at 27°C. The other two samples prepared at 500°C and 900°C had an average particle size of 9.8 and 13.5 nm, respectively. It was observed that the photocatalytic performance decreases as the crystallite size increases in the case of degradation of methyl orange. It was revealed that the as-prepared samples could be recycled eight times.

Zou et al. (2020) prepared water-soluble ZnO quantum dots modified with (3-aminopropyl)triethoxysilane (APTES) by a simple sol−gel method. They displayed strong yellow-green fluorescence. It was observed that the emission from as-prepared NH_2−ZnO QDs was quenched in the presence of Cu^{2+} ions. They designed a fluorescent probe based on an as-prepared sample of NH_2−ZnO QDs for the detection of Cu^{2+} in water with a limit of detection of 1.72 nM. This fluorescent probe had also been applied in drinking water samples. Haghani et al. (2020) also prepared ZnO-QDs using a sol−gel method and then fabricated an optical sensor based on these QDs for the determination of chlorogenic acid (CGA). Tetraethoxysilane and 3-aminopropyltriethoxysilane were used as a cross-linker and functional monomer, respectively, to prepare the molecularly imprinted polymer (MIP). As-prepared ZnO-QDs MIP composite was used to measure CGA in the range of 0.2−5.3 $\mu g\ mL^{-1}$ with a limit of detection of 0.06 $\mu g\ mL^{-1}$. This sensor was also used to measure the concentration of CGA in human plasma samples.

Wang et al. (2020) prepared graphene oxide/WO_3 quantum dots/TiO_2 (GOWT) composite. These GOWT films were prepared by using this GOWT composite powder and $Al(H_2PO_4)_3$ as adhesive and low-cost gauze as substrates. As-prepared GOWT film was used for removal of rhodamine B. It was observed that the degradation rate of rhodamine B was around 2.6 times than GO/TiO_2 films in the presence of UV light. It was proposed that GOWT films can find potential application in sewage treatment without causing any further contamination. Song et al. (2020) used an efficient method to improve the stability of $MAPbBr_3$ QDs by encapsulating them in ZrO_2 sol. It was observed that this three-dimensional network ZrO_2 colloid formed a coating on the surface of $MAPbBr_3$ QDs, which protected these QDs from acid, base, and ultraviolet light. It was revealed that the photoluminescence intensity of as-prepared nanocomposites could retain 95% of its initial value even after 4.5 h in a basic environment and 90% in an acid environment after 10 h.

Schmitz et al. (2020) prepared colloidal ethanolic dispersions of zinc oxide (undoped) and ZnO particles doped with magnesium (II) (ZnO:Mg) via a sol−gel method. The particle sizes of these QDs were found to be 4.26 and 3.65 nm, respectively. As-prepared QDs were then used as nanofillers to obtain zein-based nanocomposite films, which displayed homogeneity, good

visual appearance, and transparency. These thin films have an extended UV-blocking range in the absorbance spectra as compared to those of pure zein. It was observed that ZnO NPs, loaded into zein films exhibited 96.5 ± 4.9% inhibition of growth of *S. aureus*. It was suggested that as-prepared nanocomposites could be used for the development of food packaging and UV protective films.

The ZnS QDs/gelatin nanocomposites were prepared by Guo et al. (2020) using green one-pot method. The method shows advantages such as being an environment friendly strategy, with mild conditions, no need for organic solvents, and simple posttreatment. Here, gelatin acted as the green capping agent apart from being main component in the QDs/gelatin nanocomposites. The presence of gelatin provides the composite with a thermoresponsive sol−gel transition property. As-prepared composite with this property can find potential uses in imaging, fluorescence labeling, and controlled release.

The Fe_3O_4 quantum dots decorated silica (FS) adsorbent were prepared by Rakibuddin and Kim (2020) via a sol−gel method. The formation of Fe_3O_4 quantum dots (organically modified silica surface) with an average size of 3−4 nm was confirmed. One of the samples showed the best arsenic removal efficiency (38.2 mg g^{-1}), which was higher than Fe_3O_4 and silica particles. As-Fe_3O_4 and silica both are environmentally sustainable, therefore this composite could be a potential candidate for the removal of arsenic. Vasiljevic et al. (2020) synthesized iron titanate (Fe_2TiO_5) nanoparticles via a modified sol−gel method followed by calcination. The bandgap of as-prepared iron tantalate was around 2.16 eV. Its photocatalytic activity was evaluated for degradation of methylene blue in the presence of natural sunlight.

Wang and Li (2021) prepared ZnO quantum dots (ZQ) and Ag/ZQ nanocomposites with different percentages of Ag loadings via a sol−gel method. It was observed that the as-fabricated sample of nanocomposite (Ag content of 11 wt.%) exhibited excellent photocatalytic activity for degradation of methylene blue in the presence of Ag11/ZQ, when Ag content was kept at 11%. Xu et al. (2021) prepared CeO_2 QDs through a sol−gel method using a recursor of $Ce(NO_3)_3 \cdot 6H_2O$ as the source of cerium. Then they developed a fluorescence probe based on these CeO_2 quantum dots and used it for highly selective and ultrasensitive direct determination of 4-nitrophenol (4-NP). It was reported that the concentration of 4-NP can be determined in the range of 0.005−75.00 μM with a limit of detection of 1.50 nM. It was also revealed that as-prepared CeO_2 QDs could be applied in the determination of 4-NP in real water samples.

Li et al. (2021) developed ZnO quantum dots using a sol−gel method. They also evaluated the antibacterial activities of ZnO QDs against *Staphylococcus aureus*, *Escherichia coli*, and *Salmonella pullorum*. It was found that the particle size of ZnO QDs was in the range of 3−6 nm. It was reported that as-prepared ZnO QDs inhibited the growth of *S. aureus*,

E. coli, and *S. pullorum* by 94.75 ± 2.28%, 87.06 ± 0.98%, and 85.55 ± 1.15%, respectively. These QDs also reduced the mortality of chicks infected with *S. pullorum* effectively via regulating the balance of the intestinal flora, protecting intestine and liver.

The mesoporous graphene quantum dots-doped TiO_2 (TiO_2-GQD) nanocomposites were prepared by Zhao et al. (2021) through a sol−gel method under ultrasonic radiation. As-prepared TiO_2-GQD nanocomposites exhibited superior performance for sunlight absorption, and photocathodic protection. It was revealed that they can protect the active metal as well as reduce the corrosion rate. It was suggested that TiO_2-GQD nanocomposites could be used in marine engineering for marine corrosion protection in the future.

Zhang et al. (2021) synthesized ZnO QDs using a hydrolysis−condensation reaction. The effect of alkali bases (LiOH, NaOH, and KOH) as well as the ratio of Zn^{2+}:OH^- was investigated on the properties of as-synthesized ZnO QDs and it was observed that the particle size of ZnO QDs prepared in the presence of LiOH and NaOH was smaller as compared to that prepared with KOH. It was reported that ZnO QDs prepared with ratio of Zn^{2+}: LiOH = 1:1 exhibited the best dispersibility and fluorescence performance.

3.2.2 Sulfides

Yamane et al. (1992) prepared CdS dispersed in soda-borosilicate glasses using by the sol−gel process. They used cadmium acetate, tetramethoxysilane, sodium acetate, and triethylborate. The gel formed was exposed to H_2S at 120°C. It was observed that glass containing about 10 wt.% CdS crystallites (4−7 nm in diameter) was obtained by sintering at 590°C. Hayakawa et al. (2000) prepared rare-earth ions and semiconductor nanocrystals using Eu^{3+} doped silica gel with adsorbed cadmium sulfide particles via a sol−gel technique. It was proposed that surface-trapped electrons on CdS particles excited 4 f electrons (nonradiatively) in Eu^{3+} ions via an energy transfer process.

The CdS/ZnO quantum dots were prepared by Wang et al. (2011) via a sol−gel method. They used triethanolamine as a capping agent. The bandgaps for different ratios of CdS/ZnO (1:9, 1:1, and 9:1) were found to be 4.13, 3.93, and 3.11 eV, respectively. The size of as-obtained QDs was found to be in the range of 5−10 nm; of course with some agglomerated particles. Yang et al. (2018) prepared ZnS nanoparticles on nitrogen and sulfur codoped carbon nanosheets (ZnS@NSC) via a sol−gel synthesis. It was reported that nanosheets and ultrafine carbon shells together constituted an N, S codoped carbon framework, providing abundant active sites for sodium storage along with enhanced electrical conductivity. It was revealed that ZnS@NSC could achieve excellent cycling stability (73.6% capacity retention after 380 cycles at 0.5 A g^{-1}) and reversible capacity of 734 mAh g^{-1} at 0.5 A g^{-1}.

The ZnS/CdS/γ-TaON composite was prepared by An et al. (2019) via nitridation of Ta_2O_5 and deposition of CdS and ZnS quantum dots. It was revealed that CdS and ZnS quantum dots (3−8 nm diameter) were uniformly dispersed on the surface of γ-TaON. It was revealed that under optimized condition, H_2 evolution rate of ZnS/CdS/γ-TaON composite was 839.6 $\mu mol\ h^{-1}\ g^{-1}$, which is about 14 times higher than that of CdS/γ-TaON and 47 times higher than Pt loaded γ-TaON sample. Rakibuddin et al. (2020) prepared different MoS_2 morphologies (bulk, flake, and quantum dots) that were then fabricated onto indium tin oxide using the sol−gel method. The MoS_2 bulk, flake, and quantum dots were used as electrochromic anodic layers, and WO_3 as a cathodic layer to fabricate MoS_2/WO_3-based electrochromic devices. It was reported that as-fabricated MoS_2/WO_3 ECDs exhibited high optical contrasts (59%−75%) at 1.5−0 V and 700 nm. It was suggested that solution-processed MoS_2/WO_3-based ECDs can find an application in the processing of flexible and optical devices. Cadmium sulfide nanostructures were prepared by Sonker et al. (2020) using sol−gel method. Then CdS thin films of different thickness were prepared. They used an as-fabricated sample for gas sensing measurements for detecting 20 ppm NO_2 gas.

A phosphorescent probe of type SiO_2-Mn:ZnSQDS-MIP was synthesized by Chen et al. (2020) using MIP as a polymer coating via a sol−gel method. They used thioglycolic acid (TGA)-modified QDs, cephalexin, 3-aminopropyltriethoxysilane and tetraethoxysilane as luminescent materials, template, functional monomer, and cross-linking agent, respectively. It was revealed that cephalexin can be determined in 2.5−50 $\mu g\ L^{-1}$ concentration range with a limit of detection of 0.81 $\mu g\ L^{-1}$. The as-fabricated nanoprobe was applied for determination of cephalexin in (spiked) raw milk and milk powder. Sankar et al. (2020) synthesized Ni-doped CdS nanoparticles with 0.5%, 1.0%, 1.5%, and 2.0% via the sol−gel method. The average crystalline size of the particles was found to range from 8.70 to 9.93 nm. The SEM images indicated combination of metal oxide cubes and rod-like structures with 12−35 nm unequal grain size with excellent crystallinity quality. It was revealed that the bandgap energy decreases from 2.36 to 2.29 eV on increasing the percentage of Ni. Photocatalytic degradation of methylene blue and methyl orange was also carried out and it was found that 94% methyl orange can be degraded in 75 min.

Rempel et al. (2020) synthesized a complex sandwich catalyst, which was based on nanotubular TiO_2 and colloidal cadmium sulfide via a sol−gel method. They investigated the photocatalytic activity of this catalyst for oxidation of acetone in the gas phase under visible light and UV irradiation. Ajibade and Oluwalana (2021) prepared ODA-capped ZnS quantum dots from a bis(morpholinyldithiocarbamato)Zn(II) complex. It was confirmed that an hexagonal wurtzite crystalline phase of ZnS was present in the sample with particle sizes of about 1−3 nm. It was reported that the as-prepared ZnS can be used as photocatalysts for degrading brilliant green, rhodamine B, and their binary mixture. It was revealed that the highest photocatalytic

degradation efficiency of 94% was obtained with a sample with a low photoluminescence intensity. It was also found that ZnS quantum dots can be reused five times without any significant loss in degradation efficiency.

Zaidi and Azam (2021) synthesized zinc sulfide quantum dots using the sol−gel method. They used zinc nitrate and sodium sulfide as the source of zinc and sulfur, respectively. The particle size of as-prepared QDs was found to be 1.74 nm. The antimicrobial activity of these QDs was studied against *Pseudomonas aeruginosa*, where they exhibited good bactericidal activity. Perovskite-sensitized solar cell is an effective hybrid organic−inorganic solar cell device. Sonker et al. (2021) synthesized CdS quantum dots via the sol−gel approach. It was found that the maximum grain diameter was about ~4 nm. It was observed that as-fabricated CdS QD-based dye-sensitized solar cell and PSSC exhibited a maximum power conversion efficiency (η) of 0.5% and 1.8% at 1 Sun condition, which was improved by approximately 72% as compared to the reference cell.

3.2.3 Carbon-based quantum dots

Ke et al. (2017) prepared carbon quantum dots-modified TiO_2 photocatalysts via the sol−gel method. The photocatalytic performance of the as-prepared composite was the degradation of methylene blue in the presence of visible light irradiation and it was observed that the degradation efficiency of methylene blue was high (90%) within 2 h, which is almost 3.6 times higher than compared to TiO_2.

Ensafi et al. (2018) anchored MIP on the surface of GQDss using the sol−gel method. It was used for highly sensitive and selective determination of *p*-nitroaniline (*p*-NA) in the range of 0−15.0 μM. This was also applied to real samples of water and fish with satisfactory results. Molecularly imprinted silica was prepared via the sol−gel method by Yang et al. (2020). They used fipronil as the template, tetraethoxysilane as cross-linker, and 3-aminopropyltriethoxysilane as a functional monomer in the presence of carbon quantum dots. It was reported that blue fluorescence of the CQD@MIS, was quenched in the presence of fipronil, a commonly used insecticide. These QDs can detect fipronil in the range of 0.70 pM to 47 μM with the limit of detection being 19 pM. This method was applied for the determination of fipronil in real samples such as milk, spiked eggs, and tap water.

Yu et al. (2021) developed a composite of carbon nitride quantum dots in situ-doped TiO_2 inverse opal (TiO_2 IO) via the sol−gel method. It was reported that the as-prepared photocatalyst exhibited excellent photocatalytic degradation of toluene and 93% of toluene can be degraded into harmless products such as CO_2 and H_2O under simulated sunlight irradiation. On the other hand, only 37% of toluene was found to degrade in the presence of commercial P25. They also used this composite for the degradation of phenol and rhodamine B. Vyas et al. (2022) synthesized water-soluble, green incandescent CQDs at high yield by carbonization of water hyacinth (*Eichhornia crassipes*) weed. They

fabricated copper sulfide nanoparticles and composite CQDs@CuS. This composite was used for the photocatalytic degradation of brilliant green dye.

3.2.4 Graphene based

A fluorescent sensor was prepared by Zhang et al. (2020) based on water-soluble nitrogen-doped GQDs (N-GQDs), which were coupled with MIPs via a simple sol−gel method. It was then used for detection of tetracycline, an antibiotic. It was revealed that this method can be used in detecting the presence of tetracycline in animal-derived food.

Nickel-cobaltite/GQDs ($NiCo_2O_4$/GQDs) composites were prepared by Kharangarh et al. (2021). It was observed that the as-prepared sample exhibited improved electrical conductivity and can function as electrode materials with higher energy density compared to $NiCo_2O_4$ and GQDs. The observed specific capacitance for the fabricated composite was found to be 481.4 Fg^{-1} at 0.35 Ag^{-1}. It was higher than that of GQDs ($C_{sp} \sim 45.6\ Fg^{-1}$). It was proposed that the as-fabricated composites could be used as superior electrode materials in supercapacitors due to their unique characteristics.

Qiu et al. (2021) prepared cadmium sulfide quantum dots/dodecahedral phosphotungstic acid potassium $K_3PW_{12}O_{40}$ (KPW)/oxygen-doped mesoporous graphite carbon nitride (meso-g-C_3N_4) nanosheets with tandem heterojunctions. It was reported that the photocatalytic production rate of hydrogen formation and photocatalytic removal rate of Cr^{6+} over CdS/KPW/meso-g-C_3N_4 were found to be higher than with KPW and CdS/KPW.

3.3 Others

The CdSe quantum dots sensitized TiO_2 photocatalysts were synthesized by Shi et al. (2014) via the sol−gel method. The photocatalytic performance of as-prepared material was enhanced in the degradation of methylene blue. It was revealed that the catalysts doped with 0.05% CdSe QDs exhibited the highest activity, and the degradation efficiency of methylene blue could reach up to 99.2% within 3 h.

A solvothermal-assisted sol−gel method was reported by Anupama et al. (2021) to synthesize Se quantum dots. It was revealed that Se quantum dots having average size 3−8 nm were obtained with a trigonal crystal structure. It was found that as-prepared selenium quantum dots could work as ideal candidates for inner filter effect-based sensing of curcumin. Liu et al. (2022) synthesized the MIP@CdTe QDs through a simple sol−gel method. They used 3-aminopropyltriethoxysilane and tetraethoxysilane as functional monomer and cross-linker, respectively. These were then used for the determination of ciprofloxacin in the range of 0.5−24 μM with the limit of detection being 0.23 μM. This probe was also applied for the determination of this antibiotic in seawater samples with recoveries ranging between 98% and 110%.

3.4 Conclusion

The sol−gel process can provide nanoparticles of controlled sized and porosity along with purity. It avoids the problems of the coprecipitation method. Quantum dots of metals and metal chalcogenides, carbon, graphene, etc. can be easily prepared using this process. There is a wide scope for preparing quantum dots of different materials using this method.

Chapter 4

Laser ablation synthesis of quantum dots

Neetu Shorgar[1], **Indu Bhati**[2] **and Priyanka Jhalora**[1]
[1]*Department of Chemistry, PAHER University, Udaipur, Rajasthan, India,* [2]*Maribyrnong, VIC, Australia*

4.1 Introduction

LASER or Laser is light amplification by the stimulated emission of radiation. The first laser was built by Maiman (1960) based on theoretical work by Schawlow and Townes (1958). A laser differs from other light sources in the context that it emits coherent light. Its spatial coherence allows it to be focused on a tight spot, which is utilized in laser lithography and cutting. It also allows this laser beam to stay narrow even over great distances (collimation), which finds applications in laser lidar and pointers. Lasers can have temporal coherence also, which can be used to produce a broad spectrum with ultrashort pulses of light but their duration is short enough to be in the order of femtoseconds (10^{-15} s).

Lasers find applications in laser printers, optical disk drives, barcode scanners, fiber-optics, DNA sequencing instruments, lighting displays, laser surgery, photolithography, free-space optical communication, cutting and welding materials, skin treatments, as well as military and law enforcement devices for marking targets and measuring range and speed. The semiconductor lasers (blue to near-UV) have been used in place of light-emitting diodes (LEDs) as a white light source. Such laser devices are used in some car headlights.

4.2 Laser ablation

Laser ablation (LA) is a complex process. The laser will penetrate the surface of the sample and that depends on its wavelength as well as the refractive index of the target material used. A high electric field is generated due to laser irradiation that is enough to remove electrons from the bulk of the sample. These free electrons then collide with the atoms of the sample,

Quantum Dots. DOI: https://doi.org/10.1016/B978-0-12-824153-0.00004-5
© 2023 Elsevier Inc. All rights reserved.

transferring their energies. As a result, the target surface is heated, followed by vaporization, plasma formation, nucleation, and agglomeration, resulting in raw patio and/or quantum dots (Fig. 4.1).

The field of LA has been excellently reviewed by various researchers (Kim et al., 2017; Farshbaf et al., 2018; Ravi Kumar et al., 2019).

Mansoureh and Parisa (2018) observed that purity is a very important factor when metal nanoparticles (NPs) are to be applied in biological and medical fields. It is therefore, necessary to prepare metal NPs or quantum dots with the desired shape and size distribution.

4.2.1 Advantages

There are the following advantages in using the LA method:

- It is a simple and versatile method.
- It is relatively low-cost method except the cost of the instrument.
- It is a green approach.
- It does not require toxic chemicals or reagents.
- It provides high production rates.
- It provides good control of particle size.
- It provides particles with good monodispersity.

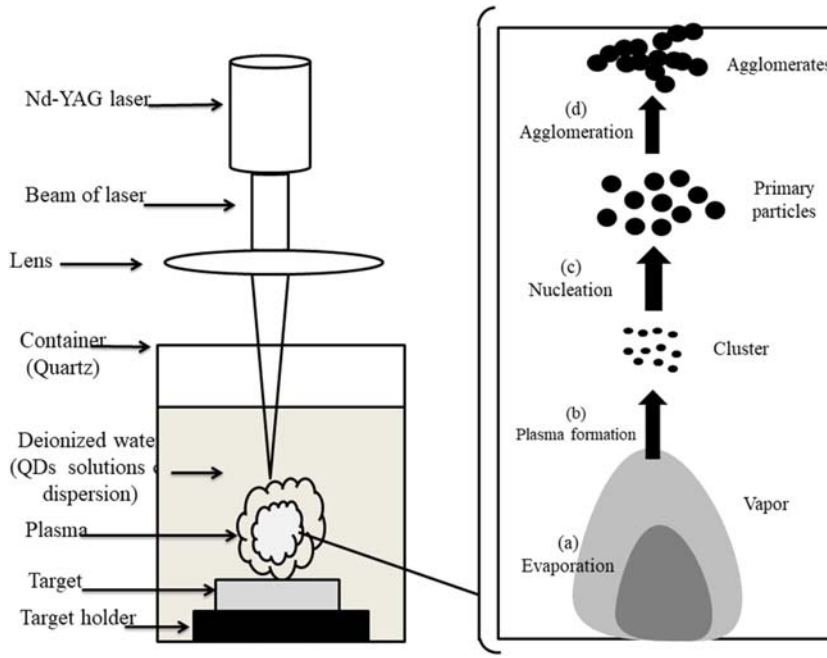

FIGURE 4.1 Laser ablation method for synthesis of quantum dots.

4.2.2 Disadvantages

The LA method has certain disadvantage also and these are:

- It has a slow rate of production of NPs.
- The consumption of energy is high.
- The cost of laser equipment is high.
- Ablation efficiency decreases on using laser for a longer period within a session.

4.3 Metal-based quantum dots

4.3.1 Metals

Silver NPs were produced by Pyatenko et al. (2004) on irradiating Ag target with a laser beam in pure water. They reported that these are very small spherical particles with size in the range of 2−5 nm.

Besner et al. (2005) obtained colloidal gold NPs using femtosecond LA of a gold plate in aqueous solutions. This method makes it possible to functionalize nanomaterial by an appropriate capping ligand. They were able to control the reactivity of as- prepared gold particles and their size by using polymers such as polyethylene glycol and dextran. The size of these NPs was found to be 5 nm, as evident from TEM images. It was also observed that long-term stability of gold particles was improved significantly on adding capping agents. A photoluminescence (PL) signal was also obtained in the violet−blue spectral range. It was revealed that as-functionalized NPs can find potential application in bioimaging and biosensing.

LA synthesis in solution (LASiS) has emerged as a new technique for synthesizing noble metal NPs (NM NPs). It is a "green" method, which does not require additional stabilizing molecules. However, presently LASiS has certain limitations in controlling the size of NM NPs, which can be overcome in the future. Amendola and Meneghetti (2009) reviewed the overview of LASiS.

Monodispersed spherical bismuth (Bi) NPs with diameters of 5−20 nm were synthesized by Verma et al. (2013) using a liquid pulsed LA method. It was reported that ablation time and surfactant ($C_{12}H_{25}NaO_4S$) both played a crucial role in the size of the NPs and their optical properties. It was proposed that such QDs can find potential applications in hypothermia treatment. Malviya and Chattopadhyay (2014) synthesized Ag−Cu alloy NPs through a LA technique under an aqueous medium in four different compositions. The observations were carried out on NPs with core−shell structure of two different sizes: ∼5 and ∼20 nm.

Kőrösi et al. (2016) synthesized ligand-free Ag NPs with particle size of 3 and 20 nm by application of picosecond LA. It was observed that a laser processing system allowed a high control on particle sizes. The effect of size

on the antibacterial activity of these as- synthesized Ag NPs was tested against *Escherichia coli* and *Staphylococcus aureus*. Li and Chen (2016) developed a new strategy for synthesizing stable and monodispersed silver quantum dots by laser fragmentation of bulk Ag in aqueous medium. They used polysorbate 80 as both a dispersing and stabilizing agent. It was revealed that surfactant played an important role in determining the size of these Ag nanostructures. The Ag QDs have excellent photostability of ~500 h and enhanced PL at 510 nm.

Ryabchikov et al. (2016) ablated a gold target using laser radiation (femtosecond) in aqueous solutions of initially prepared Si NPs. It was observed that Au-based spherical colloids were obtained with an average size in the range of 5−10 nm. It was proposed that as-prepared nanostructures can find various applications in the field of catalysis, biomedicine, and photovoltaics. Boltaev et al. (2018) observed that there is a correlation between efficient third harmonic generation in the plasmas and strong nonlinear optical response of silver NPs due to plasmon resonance. It was reported that nonlinear absorption coefficient of Ag NPs (8 nm) was high enough (3×10^{-5} cm W^{-1}) at the wavelength of 1064 nm.

Sadrolhosseini et al. (2019) fabricated gold NPs in the graphene quantum dots (GQDs) solution via LA. The particle size was controlled by changing ablation time from 5 to 25 min. A peak at 319.8 nm was attributed to GQDs. It was observed that particle size was in the range of 11.74−28.29 nm, which was found to decrease with increasing ablation time. Gold NPs in a carbon quantum dots (CQDs) solution were also prepared (Sadrolhosseini et al., 2020) using a LA method. It was observed that the variation in the photoluminescent peak in the presence of the gold NPs was higher compared to pure CQDs. It can be used for the detection of pyrene with a limit of detection of 1 ppm.

4.3.2 Metal oxides

Murali (2001) prepared indium oxide (IO) NPs via a reactive LA method. An average particle size of these particles was found to be 6.6 nm, as evident from XRD and TEM data. These laser ablated samples exhibited a blueshift of 110 meV compared to bulk material. Ajimsha et al. (2007) fabricated luminescent, transparent, and biocompatible ZnO quantum dots in three solvents (water, methanol, and ethanol) using a liquid-phase pulsed LA method. They did not use any surfactant. It was confirmed that crystalline ZnO quantum dots were found to have a uniform size distribution of 7 nm. As-prepared highly luminescent nontoxic ZnO quantum dots could find applications in the field of biomedicine as florescent probes.

A pulsed laser emitting UV radiations was used by Gondal et al. (2009) for the synthesis of nanostructured ZnO and ZnO_2. For the synthesis of NPs of ZnO_2, a highly pure metallic plate of Zn target was kept under repeated

laser irradiation in the presence of H_2O_2 as an oxidizing agent. It was reported that size, optical properties, and morphology of as-synthesized ZnO and ZnO_2 by this method were influenced by postannealing conditions. It was revealed that ZnO_2 was completely converted to ZnO by annealing ZnO_2 for 8 h at 200°C. It was reported that the size of ZnO changes from 5 to 19 nm raising the annealing temperature from 200°C to 600°C. Optical properties as well as bandgap of nano-ZnO were also changed.

Suzuki et al. (2009) used pulsed LA to prepare quantum dots of zinc oxide using differential mobility analyzer (DMA). Initially, irregularly shaped ZnO particles were obtained, but when annealing temperature was increased, then they are transformed into spherical QDs. It was observed that ZnO QDs obtained by this method were crystallized (single crystallites) with a wurtzite structure. The ZnO QDs with average size in the range of 4.8−8.1 nm could be easily prepared by reducing the specified sizes of DMA.

Zheng et al. (2010) prepared ultrafine Y_2O_3:Pr, Yb NPs using femtosecond pulsed LA. It was reported that these spherical particles have a size of about 10 nm (diameter) with a narrow size distribution. As-prepared NPs exhibited significantly improved upconversion intensity as compared to NPs, which were prepared by the sol−gel method.

Zeng et al. (2011) synthesized ZnO quantum dots through laser irradiation of hollow nanospheres of ZnO in liquid medium. It was reported that as-synthesized QDs have diameters ranging between 1 and 8 nm, exhibiting a quantum size effect, which can be tuned by variation of parameters of the laser irradiation process. It was observed that the main PL emission bands evolved are from blue to green, finally reaching ultraviolet peaks. These as-fabricated QDs can show optical and optoelectronic applications.

Eita et al. (2012) fabricated thin UV-blocking films of poly(methyl methacrylate) (PMMA) and ZnO quantum dots via spin-coating. It was revealed that an average thickness of bilayer before heating was 9.5 nm, which reduces to 8.6 nm after heating at 100°C for 1 h. It was also observed that surface roughness was 3.6 and 8.4 nm for one and ten bilayer films, respectively, as evident from atomic force microscopy. The absorption of UV radiation increases with increasing number of bilayers, but transmission was damped at wavelength <375 nm. It was reported that thin films had a high transparency in the visible region. The single layer of PMMA/ZnO QDs thin films was found to be hydrophobic in nature.

Singh and Gopal (2012) used nanosecond (ns) pulsed LA of zinc rod, which was placed on the bottom of a glass vessel containing methanol. As a result, a colloidal solution of drop-shaped zinc oxide quantum dots and their self-assembly into different dendritic nanostructures were obtained. It was observed that average length, width, and aspect ratio of these as-prepared drop-shaped zinc oxide quantum dots were found to be 6 ± 2.4 nm, 3.5 ± 1.4 nm, and 1.69 ± 0.4 nm, respectively. Its PL spectrum exhibited emission peaks in UV, violet, blue, and green spectral regions.

The SnO_2 quantum dots were synthesized by Singh et al. (2012) using LA in liquid. The diameter of the SnO_2 NPs was found in the range of 1−5 nm as evident from HRTEM images. As-prepared SnO_2 QDs exhibited tetragonal crystalline structure. Their PL spectrum showed green and blue emission peaks at 540 nm and 445 nm, respectively. It was proposed that these QDs have great potential for use in biosensors, optoelectronics, etc. Patel et al. (2013) synthesized SnO_2-QDs ($\sim$ 1−5 nm) by LA technique in liquid. Then these QDs were electrophoretically deposited onto the surface of indium tin oxide (ITO)-coated glass electrodes. Then ssDNA/SnO_2-QDs/ITO bioelectrodes were fabricated and these bioelectrodes have been used for DNA hybridization.

Drmosh et al. (2019) fabricated ZnO NPs by decomposing zinc peroxide (ZnO_2) quantum dots, which were synthesized by LA of microstructured Zn powder in 3% H_2O_2. Then rGO/ZnO nanocomposite was prepared from them via pulsed LA in liquid (PLAL). The surface of the rGO/ZnO hybrid was decorated with a Pt thin film so as to get a ternary rGO/ZnO/Pt hybrid nanocomposite. It was observed that this Pt-loaded rGO/ZnO gas sensor (thickness of 2 nm) exhibited selectivity and excellent response for sensing a low concentration of hydrogen. This nanocomposite was found to be 10 and five times better than pure ZnO, and rGO/ZnO nanocomposite, respectively. It was proposed that rGO/ZnO/Pt hybrid nanocomposite is a potential promising candidate for fabricating high-performance gas sensors for H_2.

Mitra et al. (2019) prepared highly crystalline p-type manganese oxide (MnO) wide bandgap semiconductor quantum dots via femtosecond-LA in liquid. This p-type MnO QD material could find applications in the industrial production of high-performance solution-processed deep UV optoelectronics on a large scale. Mostafa et al. (2019) synthesized tungsten oxide QDs with pulsed laser−assisted ablation. They used tungsten (tablet) as a target in liquid media. This method is a green chemical method as it uses only tungsten tablet and water for preparing tungsten oxide without impurities. It was confirmed by morphological analysis that the as-prepared tungsten oxide NPs were quantum dots with average diameter of about 5 nm. They used these as-prepared samples as the catalyst for the degradation of 4-nitrophenol.

Mwafy et al. (2019) prepared zinc oxide NPs using CQD solution through a LA technique. It was observed that ZnO-NPs in the CQD solution were formed with capping of the ZnO NPs (spherical) by a functional group of the CQD. As-prepared ZnO-NPs in the CQD solution had a particle size in the range of 7.5−14.03 nm. These prepared samples were used in the detection of lead and mercury ions in aqueous solution and it was found that a PL peak shift was greater in the presence of mercury ions compared to lead ions.

Kateshiya et al. (2020) developed a facile synthetic route for preparing highly blue fluorescent tyrosine-coated molybdenum oxide quantum dots (Tyr-MoO_3 QDs). They used tyrosine as a surface ligand for the functionalizing MoO_3 QDs.

It was revealed that as-prepared Tyr-MoO_3 QDs could act as a sensor for sensitive as well as rapid identification of imidacloprid via fluorescence quenching mechanism. The as-developed probe was also applied for detection of imidacloprid in real samples.

Wang et al. (2021) synthesized multifunctional ZnO, which was decorated on Fe hierarchical nanostructures using LA technique. They decorated ZnO quantum dots on Fe nanowires, ZnO nanospindles cluster on Fe core and flocky Fe@ZnO core−shell nanospheres (Fe@ZnO CSNSs). As-synthesized Fe@ZnO CSNSs were then used for the photocatalytic degradation of rhodamine B. It was reported that photocatalytic removal of rhodamine B was about 94.1% in the presence of natural light irradiation for 20 min.

4.3.3 Metal sulfides

Formation of quantum dots of ZnSe and CdS was reported under ablation of bulk semiconductors in a liquid environment (ethanol, diethyleneglycol, etc.) by Anikin et al. (2002). It was confirmed that these quantum dots are crystalline in nature with an average size of ∼10−20 nm. Lalayan (2005) prepared colloidal quantum dots of GaAs and CdS semiconductors through LA in the liquid media. The large blueshift of the PL was evaluated, and it was connected to size effects. Luminescence spectra at the wavelength 405 nm (CdS) and 420 nm (GaAs) indicated that sizes of QDs were in the range 2−3 nm.

Zheng et al. (2008) synthesized Cu-doped ZnS (ZnS:Cu) quantum dots in deionized water using femtosecond LA of a bulk (ZnS:Cu) target. It was reported that these quantum dots exhibited good water solubility and colloidal stability. An average size of as-prepared quantum dots varied in the range of 2.1−4.0 nm on changing the laser fluence. It resulted in a redshift of the emission peak.

Ka et al. (2011) synthesized lead sulfide (PbS) NPs layers onto different substrates at room temperature using pulsed laser deposition (PLD). It was reported that average size of these NPs can be controlled by changing the number of LA pulses. A blueshift in PL was observed from 1420 to 880 nm. As-prepared PbS NPs had a diameter of 8.5 nm, which was decreased to 2.5 nm, which confirmed the quantum size effect. Khan and BiBi (2014) synthesized densely packed CdS NPs using ns-pulsed LA. The average size of these NPs was found to be in the range of 5−10 nm. An energy bandgap of around 3.03 eV was attributed to band-to-band transition in CdS.

Ka et al. (2012) used the pulsed LA technique for direct synthesis of single-walled carbon nanotube/PbS-quantum dot (SWCNT/PbS-QD) nanohybrids (NHs). This not only permitted control on the size of the PbS-QDs but also made it possible for integration of these SWCNT/PbS-QD NHs into photoconductive devices with a strong photoresponse. Ka et al. (2014) used a PLD technique for fabricating NH heterojunctions (NH-HJs) solar cells.

They decorated TiO_2 nanorods (TiO_2-NRs) on PbS quantum dots (PbS-QDs). They could achieve NH-HJs-based PV devices with high power conversion efficiency (PCE) (4.85%). It was interesting to note that the PCE of these devices was found to be quite stable for several months in the presence of air. It was also reported that the addition of SWCNTs onto the TiO_2-NRs before decorating them by PbS-QDs further enhanced PCE to 5.3%, which may be due to more light absorption and improved charge collection by SWCNTs.

Darwish et al. (2015) synthesized size-tunable (5−12 nm) cadmium sulfide (nano II−VI semiconductor) with different shapes, such as rod, sphere, rope, etc., using a pulsed laser in liquid environment method. It was confirmed that the NPs are crystalline. These nanomaterials can find application in biosensing and photonics. Gondal et al. (2015) prepared TiO_2/ZnO/CdS QDs using a PLAL technique. Here, ZnO reduces the electron−hole recombination in the TiO_2 while CdS will increase the light harvesting efficiency of TiO_2. The morphology of the composite quantum dots was observed by high-resolution TEM indicating that the size of the composite ranges between 10 and 40 nm. Such a composite can be used for energy harvesting using sunlight.

Baldovi et al. (2016) synthesized MoS_2 quantum dots in colloidal suspensions by LA of commercial MoS_2 in acetonitrile. It was found that there was a lateral size distribution from 5 to 20 nm, as evident from HRTEM images. It was also revealed that these MoS_2 QDs were constituted by 3−6 MoS_2 layers (1.8−4 nm thickness). It was predicted that its photocatalytic activity may be enhanced for H_2 generation in the presence of UV−Vis irradiation using methanol as a sacrificial electron donor. Ka et al. (2016) decorated SWCNTs with PbS quantum dots by the PLD method. As a result, SWCNTs/PbS-QDs NHs were formed. It was found that the number of pulses controlled the average size of PbS-QDs as well as their coverage on the SWCNTs surface. The photoconductive devices were fabricated from these NHs exhibiting an enhanced photoresponse, which was dependent on size of PbS-QDs. The diameter of PbS-QDs was found to be 6.5 nm and bandgap was calculated as 0.86 eV.

The CdS quantum dots with a narrow size distribution were synthesized by Mendonça and de Azevedo (2016) having emission range of 400−700 nm. These were very stable, water-dispersible, and bright. They used a combination of LA technique and thioglycerol, which acted as a catalyst for the hydrolysis of thiosulfate as well as a stabilizing agent. The decomposition of thiosulfate catalyzed by thioglycerol produced S^{2-} ions, which interacted with Cd^{2+} ions to form CdS quantum dots. It was observed that the particle size of monodispersed CDs QDs was about 2.75 nm. As-prepared QDs exhibited bright PL in the yellow-orange region.

Li et al. (2017) fabricated monolayer MoS_2 QDs. They used temporally shaped femtosecond LA of bulk MoS_2 in water. It was revealed that
