Ariaeenejad *et al*. [25] presented a dual crosslinking (DC) strategy to synthesize novel 3D networks of carboxymethyl cellulose grafted copolymers of 2-acrylamido-2-methyl propane sulfonate and acrylamide (CMC-g-poly(AMPS-

co-AAm)) hydrogels. They utilized graphene oxide nano-sheets as nano-fillers and physical cross-linkers, making H-bondings between polymeric chains to prepare GO@CMC-g-poly(AMPS-co-AAm) networks. The effects of GO content on the performance of as-synthesized material was examined with a model enzyme (PersiCel1). It was revealed that persiCel1 immobilization on the GO reinforced hydrogels retained almost 60% of its maximum activity at 90°C. Its specific activity and storage stability were remarkably enhanced. The immobilized enzyme on the GO containing hydrogels showed a 154.8% increase in conversion of alkaline-treated sugar beet pulp compared with the free PersiCel1, while the PersiCel1/neat-hydrogel indicated only an increment of 66.7% under the same conditions.

Ranjbari *et al*. [26] reported the synthesis of graphene oxide nanosheets (GON) by a modified Hummer's method. Then they immobilized a protease purified from the *Penaeus*vannamei shrimp on the GON activated with glutaraldehyde. It was observed that immobilization of the protease on the GON activated with glutaraldehyde did not affect the optimum pH much, but it significantly improved thermal stability and stability at extreme pH values, as well as activity at 90°C. It was interesting to note that the free enzyme retained less than 10% of the activity, but immobilized enzyme could retain more than 90% of its original activity after 24h of incubation at 90°C. The immobilized enzyme exhibited higher activity for hydrolysis of casein at 70°C and in the presence of 2M urethane than that of the free enzyme.

The effect of the hydrophobicity of reduced graphene oxide (rGO) on the activity of candida rugose lipase (CRL) was studied by Chen *et al*. [27]. They observed that the higher hydrophobicity of rGO surface could increase CRL activity, but it decreased the activity. It was revealed that the rGOB showed a three-dimensional micro-nanoporous structure and surface hydrophobicity with improved adsorption properties and catalytic activity of CRL. It was reported that CRL was immobilized onto the beads by physical adsorption with the maximum adsorption capacity of 117.67 mg g^{-1}. The immobilized lipase (rGOB@CRL) exhibited good temperature, thermal, and reuse stability as compared to free CRL. The conversion rate of triglycerides (TG) in the free enzyme reaction system in the glycerolysis reaction of olive oil was found to be only 67.83%, while the conversion rate of TG in the $rGOB_4$@CRL reaction system could reach 74.87%. As-synthesised rGOB@CRL can be used to adsorb emulsified oil due to the excellent oil-absorbing ability of rGOB, producing monoglyceride (MG) and diglyceride (DG) *in situ* by catalyzing the glycerolysis reaction. The conversion rate of triglyceride (TG) could reach 89.70%, when the oil concentration was kept 4 mg mL^{-1}.

Agrawal *et al*. [28] immobilized *β*-amylase onto GQDs using 3-aminopropyltriethoxysilane and glutaraldehyde. It was reported that the predicted optimum immobilization efficiency (88.64%) was quite close to the actual value (87.98%), and it confirmed that the immobilization process was successful. The immobilized enzyme exhibited maximum activity at pH 5.0 and 57°C, The K_m and V_{max} were found to be 6.40 mg mL^{-1} and 714.28 μmol^{-1} min^{-1} mg, respectively. The enzyme could retain 75% activity even after 12 uses at 30°C. An increase in thermostability of immobilized fenugreek *β*-amylase and non-toxic nature of GQDs could be used for maltose production in beverage, food and pharmaceutical industries.

Laccase enzymes of *Aspergillus oryzae* were immobilized on graphene nanosheets by Skoronski *et al*. [29] *via* physical adsorption and covalent bonding. It was carried out through contact between graphene and a solution of laccase enzyme, which was dissolved in deionized water. It was reported that this adsorption process followed a Freundlich model, while the process of immobilization by covalent bonding was carried out by nitration of graphene. It was followed by a reduction of sodium borohydride and crosslinking with glutaraldehyde. It was observed that process of immobilization by both these techniques increased the pH range of its activity as compared to the free enzyme and also its operating temperature. It was found that the enzyme quickly lost its activity after the second reaction cycle, when it was immobilized *via* physical adsorption. It retained about 80% of it activity after six cycles.

Wang *et al*. [30] fabricated hydrophilic polyethylenimine (PEI) modified magnetic graphene oxide composite (Fe_3O_4@PDA@GO-PEI) and used it as efficient solid support for the immobilization of dextranase, so as to improve stability and recyclable performance. It was reported that GO nanosheet component not only provided abundant binding sites for decorating PEI molecules, but it increased the loading capacity of immobilized dextranase further and acted as a soft matrix to enhance its stability. A combination of the magnetic separation property and the recyclable ability of immobilized dextranase was found to be further improved. The loading amount of immobilized dextranase on as-developed Fe_3O_4@PDA@GO-PEI was determined to be 305.1 mg g^{-1}, and it was about 1.61 times that without GO component. It was revealed that as-developed Fe_3O_4@PDA@GO-PEI-dextranase exhibited high immobilization efficiency (76.27%) enzymatic activity (83.67%), improved stabilities in a wide range of temperature and pH conditions.It retained 85.78% of its initial activity even after 20 cycles. It was suggested that the immobilized dextranase has a potential for various applications in biocatalytic engineering fields.

Alpha-amylase was immobilized by Mulko *et al*. [31] inside three different polymeric matrices (polyacrylamide hydrogel) PAAm; polyacrylamide-graphene oxide nanocomposite, PAAm-GO; and alginate so that effect of the matrix on the catalytic performance can be compared. They also studied morphology, swelling, mechanical properties, retention efficiency, and the catalytic behaviour of supported biocatalysts. It was found that nanocomposite made of PAAm-GO matrix incorporated 98% of the enzyme, which may be due to cooperative effect, while alginate gels incorporated only 30%. The enzyme retention using PAAm-GO could achieve a value of 97.5%. It was reported that PAAm matrices protect the biocatalyst so that it can be reused. An improvement in catalytic properties of enzyme *via* immobilization makes it an excellent candidate in bioindustrial applications. It will therefore be possible to produce sequential or simultaneous saccharification and fermentation using it.

Atiroğlu [32] made some efforts to develop stability in *lipase B Candida antarctica* as Cross-Linked Enzyme Aggregates (CLEAs). Grapheneoxide nanoparticles (GO-MNPs) were prepared for this purpose. Different operating conditions were compared, such as temperature, pH, storage stability, reusability, and organic solvents. It was reported that saturated ammonium sulfate (55%) and cross-linked with 125mM glutaraldehyde for 10h at 4°C were found to optimize the synthesis of lipase-GO-MNPs-CLEAs with the maximum activity recovery of 96.5%. Hyaluronicacid (HA) was used to modify MNPs, which improved the stability and nano-biocatalytic performance so that it can be used in industrial applications.

D-Psicose (D-ribo-2-hexulose or D-allulose), (an epimer of D-fructose) is considered as a rare low-calorie sugar and its enzymatic production using ketose 3-epimerases is a feasible process for the production of D-Psicose. But there are some drawbacks in the application of ketose 3-epimerases, such as bioconversion efficiency and reusability of the enzyme. Dedania *et al*. [33] immobilized ketose 3-epimerases from *Agrobacterium tumefaciens (agtu)* D-psicose 3-epimerase (DPEase) on graphene oxide. It was reported that graphene oxide immobilized *agtu*-DPEase (GO-*agtu*-DPEase) had optimal pH 7.5 and temperature 60°C. A significant improvement in thermal stability was observed, which showed a half-life of 720 min at 60°C, while *Agrobacterium tumefaciens (agtu)* DPEase displayed only 3.99 min. The bioconversion efficiency accounted for graphene oxide immobilized DPEase at equilibrium, 40:60 (D-psicose: D-fructose), which is higher than the *agtu*-DPEase. It was observed that graphene oxide immobilized DPEase exhibited bioconversion efficiency up to 10 cycles of consecutive uses.

A simple, and efficient approach has been reported by Lin *et al*. [34] to fabricate a biocatalytic system by immobilizing the enzyme onto graphene oxide nanosheets

by two methods for the practical application of Bacillus licheniformis γ-glutamyltranspeptidase (BlGGT) *via* both; non-covalent (GO-BlGGT) and covalent (GO/GA-BlGGT) bonds. It was found that the enzyme-loading capacity for the prepared GO/GA nanomaterial was 3.47mg mg^{-1} support, corresponding to a 68.7% recovery of the initial activity. The immobilized enzymes exhibited significantly higher activity as compared to the free form of BlGGT, may be due to the beneficial effect of the layered GO carrier. It was revealed that covalently immobilized enzyme had comparable stability with respect to free enzyme during a storage period of 30days and it could be recycled nine times, retaining about 45.3% of its initial activity. Apart from it, the biocatalytic synthesis of γ--glutamyl-phenylalanine and γ-l-glutamyl-leucine by immobilized enzymes resulted in a yield > 31%.

Orfanakis *et al*. [35] synthesized hybrid nanostructures of magnetic iron nanoparticles and graphene oxide. They used these as nano supports for the covalent immobilization of β-glucosidase. It was revealed that the immobilization efficiency depends on the structure as well as the surface chemistry of nanostructures used. As-obtained hybrid nanostructure-based biocatalysts exhibited a two to four-fold higher thermostability as compared to the free enzyme, and also an enhanced performance at higher temperatures (up to 70°C); that too in a wide pH range. It was claimed that these biocatalysts retained up to 40% of their bioactivity after twelve cycles.

Biofunctionalization of Protein

As biological macromolecules have an essential role in our daily life; thus, it is important to control the activity and stability of such macromolecules. The most promising mothed for enhancing in activity and stability is to immobilize proteins on different support materials. Furthermore, large surface area and surface functional groups are the important features that are required for a better support system. Chaudhary *et al*. [36] opined that these features of graphene oxide and reduced graphene oxide make them ideal support materials for protein immobilization. The successful formation of GO/RGO-protein complexes with enhancement in structural/thermal stability may be due to various interactions at the nano-bio interface, making their utilization in various functional applications. It was emphasized that mechanism and interactions (hydrophilic, hydrophobic, electrostatic, local protein-protein, hydrogen bonding and van der Walls) between protein and GO/RGO influence structural stability and activity of enzymes/proteins. Furthermore, GO/RGO-protein complexes are utilized in various applications such as biosensors, bioimaging and theranostic agent, targeted drug delivery agents, and nanovectors for drug and protein delivery.

Wang *et al*. [37] constructed a hybrid composite of gold nanoparticles, phospholipids bilayer membrane, and graphene and there used this composite as matrices for microperoxidase-11 (MP11) immobilization. They also investigated direct electrochemistry and corresponding bioelectrocatalysis of the enzyme electrode. Phospholipid bilayer membrane was found to protect gold nanoparticles (Au NPs) assembled on polyelectrolyte functionalized graphene sheets may be due to electrostatic attraction to form a hybrid bionanocomposite. Due to the biocompatible microenvironment, which was (provided by the mimetic biomembrane) microperoxidase-11 entrapped in this matrix retained its original structure well and thus, exhibited higher bioactivity. The Au NPs–graphene assemblies, could also promote the direct electron transfer efficiently between the immobilized MP11 and the substrate electrode. As-prepared enzyme electrodes exhibited good direct electrochemistry and electrocatalytic responses to the reduction of hydrogen peroxide. The resulting H_2O_2 biosensor showed a low detection limit (2.6×10^{-6} M), broad linear range (2.0×10^{-5}–2.8×10^{-4} M), stability and good reproducibility. This sensor was used for real-time detection of H_2O_2 dynamically released from the tumor cells MCF-7 in response to a pro-inflammatory stimulant.

Biosensors

Narwal and Pundir [38] fabricated an improved amperometric biosensor by immobilizing glycerol kinase (GK) and glycerol-3-phosphate oxidase (GPO) nanoparticles (NPs) onto graphene oxide nanoparticles (GrO NPs) modified pencil graphite (PG) electrode. It was reported that this biosensor exhibited optimal current response at an applied potential of 0.45V and pH8.0 at 35°C. It displayed a wide linear response for glycerol concentration 0.001-60mM with a detection limit of 0.002μM. A very high sensitivity ($121.45\mu A \cdot mM^{-1} \cdot cm^{-2}$) and rapid response time (2s) were there. It was revealed that 98.5% analytical recovery was there on adding glycerol to the sera samples. The biosensor was used to measure blood serum glycerol levels in patients suffering from hyperglyceridemia. It was indicated that 25% of its initial activity was lost after its regular use for a period of 210 days or more at 4°C under storage conditions.

Two-dimensional GO nanosheets and one-dimensional lysozyme nanofibrils were hybridized by Wu *et al*. [39] through electrostatic interaction to obtain a novel amyloid-GO composite. It provides a biocompatible immobilization platform for Au nanocatalysts as well as enzymes, which could load a large and tunable amount of Au NPs and its high catalytic activity was also maintained. These immobilized catalysts showed high electrochemical behaviors, which is ideal as glucose sensing systems. It was reported that enzymes could also be immobilized

on the residual bare surfaces of amyloid-GO, which could serve as a sensitive and selective analytical glucose-detecting platform.

A competitive-displacement reaction strategy based on target-induced dissociation of gold nanoparticle coated graphene nanosheet (Au NPs/GN) from CdS quantum dot functionalized mesoporous titanium dioxide (CdS QDs/TiO_2) was designed by Cai *et al*. [40] for the sensitive photoelectrochemical (PEC) aptasensing of prostate-specific antigen (PSA) through the exciton–plasmon interaction (EPI) between CdS QDs and AuNPs. To construct such an aptasensing system, capture DNA was initially conjugated covalently onto CdS QDs/TiO_2-modified electrode, and then Au NPs/GN-labeled PSA aptamer was bound onto biofunctionalized CdS QDs/TiO_2 *via* hybridization chain reaction of partial bases with capture DNA. The introduction of AuNPs/GN efficiently quenched the photocurrent of CdS QDs/TiO_2 due to energy transfer. Upon addition of target PSA, the sandwiched aptamer between CdS QDs/TiO_2 and AuNPs/GN reacted with the analyte; thus, resulting in the dissociation of Au NPs/GN from the CdS QDs/TiO_2 to increase the photocurrent. Under optimum conditions, the aptasensing platform exhibited a high sensitivity for PSA detection within a dynamic linear range of 1.0 pg mL^{-1} to 8.0 ng mL^{-1} at a low limit of detection of 0.52 pg mL^{-1}. The interparticle distance of exciton–plasmon interaction and contents of AuNPs corresponding to the EPI effect in this system were also studied. Good selectivity and high reproducibility were obtained for the analysis of the target PSA. Importantly, the accuracy and matrix effect of the PEC aptasensor was evaluated for the determination of human serum specimens and newborn calf serum-diluted PSA standards, giving a well-matched result with the referenced PSA ELISA kit.

A simple and versatile method has been described by Liu *et al*. [41] to construct high-performance three-dimensional (3D) graphene-based enzyme biosensor. They used carbon nanotubes (CNTs) as carriers of methylene blue molecules to immobilize them on 3D graphene surface through strong π-π stacking force. The polydopamine (PDA) layer could also effectively prevent the leakage of inner electron mediators. The as-fabricated biosensor exhibited an outstanding performance for reagentless detection of hydrogen peroxide in terms of wide linear range (0.2 M-1.1 mM), high sensitivity (227.8 μA mM^{-1} cm^{-2}), low detection limit (58.0 nM), and fast response (reaching 95% of the steady current within 3 s). It was also revealed that biosensors exhibited high reproducibility and stability also.

Au nanoparticles and TiO_2 nanosheets co-modified reduced graphene oxide nanocomposite (Au-TiO_2NSs-rGO) were synthesized by Liu *et al*. [42] *via* a simple synthetic route and then used to immobilize hemoglobin (Hb) in order to fabricate a mediator-free biosensor. It was revealed that the Au-TiO_2NSs-rGO

would act as immobilization support for Hb, which afforded good protein stability and bioactivity. It was reported that direct electron transfer of Hb was facilitated with the special structure of Au-TiO_2NSs-rGO. This biosensor displayed good performance for the detection of H_2O_2 in a wide linear range of 7.5~250 μM with a low detection limit of 3 μM, supported by fast response and good stability.

Various multi-tapered (four, five, and eight tapered) optical fiber sensors (OFSs) have been developed by Zhu *et al*. [43]. They immobilized different nanomaterials, such as gold nanoparticles (Au NPs) and graphene oxide (GO) over the bare probe. These nanomaterials immobilized probes were then functionalized with ascorbate oxidase. The Au NPs were found to be well-suited for biosensing applications. GO-based materials were also equally promising in nanostructure-based optical sensing due to their good chemical stability,broad surface area, high electrical conductivity, and excellent mechanical behavior. The performance parameters of this sensor were found to be greatly improved such as sensitivity (8.3 $nmmM^{-1}$), correlation correlator (0.9724), and limit of detection (51.94 μM).

A novel and sensitive electrochemical biosensor were constructed by He and Liu [44] for detecting phosphate using AuNRs@Cu_2O-NDs loaded poly (diallyldimethylammonium chloride) (PDDA) functionalized graphene immobilized pyruvate oxidase (PyO). PDDA-Gr (which has good conductive ability) was used to increase the active site and supporting substrate of biosensor. Then AuNRs@Cu_2O-NDs composite material was prepared to enhance the capability for PyO immobilization and achieved fast electron transfer between hydrogen peroxide and Cu_2O-NDs to amplify the electrical signal. The proposed biosensor showed a wide linearity range from 0.01-80μM and a low detection limit of 0.4nM under optimal conditions. This biosensor exhibited satisfactory anti-interference, good stability, and excellent reproducibility when it was applied to the monitoring of phosphate content in food.

Centeno *et al* [45]. isolated a new plant peroxidase from the leaves of guinea grass (Panicum maximum). This peroxidase had a specific activity of 408 U mg^{-1} and a molecular weight of 30 kDa. It showed optimum activity at pH 8.0 and high thermostability at 66°C. The best substrates for this peroxidase from guinea grass are o-dianisidine and 2,2′-azino-bis-(3-ethylbenzthiazoline-6-sulfonic acid). The graphene-modified electrode exhibited excellent electrocatalytic activity for reduction of H_2O_2, with a linear response in the range (100 μM-3.5 mM)with detection limit of 150 μM.

Liu *et al*. [46] reported a hydrothermal method to prepare reduced graphene oxide (rGO)-based hydrogel (GelrGONR), using neutral red (NR) to mediate the

assembly of rGO sheets and tune the pore size of GelrGONR. A large pore size of up to 20 μm and interconnected porous structure of GelrGONR were observed. The GelrGONR-M was used as a biocatalyst for establishing a BOD biosensor and it exhibited a linear range of 2–64 mg O L^{-1} and a detection limit 0.4 mg O^{-1} for glucose–glutamic acid (GGA). This BOD detection strategy had long-term viability over one year and stability up to 2 months with a relative standard deviation of 2.1%.

A novel nanocomposite material prepared by Povedano *et al*. [47], which consists of reduced graphene oxide/Rh nanoparticles through a one-pot reaction process. It involved simultaneous reduction of both; $RhCl_3$ and graphene oxide with $NaBH_4$ as well as in situ deposition of the metal nanoparticles on the 2D carbon nanomaterial planar sheets. Glassy carbon electrode was coated with this nanocomposite and it was used as nanostructured support for the cross-linking of the enzyme laccase with glutaraldehyde to provide a voltammperometric biosensor for 17β-estradiol in the 0.9^{-11}pM range. This biosensor showed excellent analytical performance with high sensitivity of 25.7 A μM^{-1} $cm^{-1}$with a very low detection limit of 0.54 pM and high selectivity. It was applied to fast determination of the hormone in spiked synthetic and real human urine samples.

Amperometric biosensors based on glassy carbon electrodes (GCE) were modified with graphene oxide (GO) and multi-walled carbon nanotubes (MWCNTs) by Vlamidis *et al*. [48]. Two types of biosensors were realized using tyrosinase (Tyr) or laccase (Lac). The enzyme immobilisation on the modified GC was optimised employing different agents (bovine serum albumin and glutaraldehyde as crosslinking agent, Nafion, and chitosan). The conditions for the fabrication and the storage of the biosensors were established in order to obtain high sensitivities, good enzyme retention, and long-life devices. This biosensor was used for the determination of catechol, pyrogallol, epicatechin, gallic acid, 1,2-dihydroxybenzoic acid, caffeic acid, chlorogenic acid, rutin, catechin and dopamine. These were also used for the determination of total polyphenols concentration in juice samples.

Hashim *et al*. [49] used the spin coating technique for the preparation of tyrosinase immobilized graphene oxide thin film on a gold surface. It was revealed that the thin film is homogeneous, where the surface of graphene oxide is covered by tyrosinase as evident for AFM studies. The thin film has high absorbance value with a band gap of 4.082 eV. This modified thin film could sense the sensing presenceof phenol with a sensitivity of 0.00234° μM-1 and the ability to detect phenol down to 1 μM.

Zrinski *et al*. [50] developed a simple and highly sensitive electrochemical biosensor based on laccase immobilized onto a gold nanoparticles/graphene nanoplatelets-modified screen-printed carbon electrode (LACC/AuNP/GN-Pl/SPCE), and then it was used for the determination of hydroquinone (HQ) and other phenolic compounds. This biosensor shows excellent electrocatalytic activity towards the oxidation of hydroquinone at a potential of -0.05V (vs Ag/AgCl, 3M KCl) in phosphate buffer as supporting electrolyte (0.1M, pH 7.0) using hydrodynamic amperometry.

The biosensor was then applied to the determination of phenolic antioxidant capacity (AOC) in wine and blueberry syrup based on Trolox (6-hydroxy-2,5,7-8-tetramethylchromane-2-carboxylic acid) and hydroquinone equivalents. The results were found to be satisfactory and agreed well with the results of the reference method.

Enzymatic Biofuel Cells

Biofuel cell is a bioenergy device, which is useful in areas of biomedicine, bioelectronics, *etc*. Enzymatic biofuel cells are a class of biofuel cells which utilizes enzymes to generate energy from renewable sources.

Graphene has excellent electrical conductivity and ease of functionalization. As a result, it is considered a promising material for use in enzymatic bioelectrodes and biofuel cells. Such biofuel cells have attracted the attention of scientists due to their potential to harvest energy from organic materials.

Xie and Huang [51] encapsulated magnetic Fe_3O_4 nanoparticles in graphene oxides, and then these were employed as a magnetic carrier for the immobilization of lipase from *Candida rugosavia* interfacial activation of enzyme on hydrophobic surfaces. It was reported that activity recovery of 64.9% and enzyme immobilization efficiency of 85.5% could be achieved using the immobilization strategy. It was observed that Fe_3O_4 nanoparticles were successfully encapsulated into GO, and the lipase was tethered on this magnetic support. The immobilized lipase could efficiently catalyze the transesterification of soybean oil with methanol and produce biodiesel and the yield was 92.8% at 40°C. It was claimed that immobilized lipase could be easily recovered and recycling of the biocatalyst was possible five times without any significant loss of its activity.

Babadi *et al*. [52] fabricated 3-dimensional graphene (3DG)/glucose oxidase (GOx) bio-nanocomposite just to improve enzyme immobilisation and enzyme lifetime with an enhanced electron transfer rate. These enhancements were attributed to the unique physical properties of 3DG, (high porosity, large surface area, and excellent electrical conductivity). They could achieve a power density of

164 μW cm^{-2} at 0.4 V from this enzymatic biofuel cell (EBFC), which is comparable to that of the other glucose biofuel cells (GBFCs). This 3DG enhanced the enzyme lifetime, but decreased enzyme leaking and as a result, its good conductivity facilitates the electron harvest and transfer from the enzyme active site to the electrode.

Microfluidic microbial fuel cells (μMFC) combine the microfluidic technology and biocatalysts anchored at the electrode, representing an emerging bio-power generator. However, a major challenge towards further development is their low bio-catalysts loading on the electrodes. It has already been revealed that bioelectrode structure and nutrient-feeding type played a significant role in the power generation of μMFC. Yang *et al*. [53] fabricated a membrane-free μMFC with a piece of graphene-decorated nickel mesh as bio-anode. It was indicated that mixed bacteria grow densely on the surface of the electrode. Due to enriched bacterial colonization and sufficient nutrient supply, μMFC produces a remarkably high areal power density of 1.11 W m^{-2} at a current density of 2.15 A m^{-2}, which was higher than those obtained with conventional two-dimensional electrodes and flow-over architectures.

A nanocomposite comprised of graphene (G) supported manganese dioxide (MnO_2) incorporated into the network of polythioaniline (MnO_2-G/PTA) was synthesized by Perveen *et al*. [54]. This hybrid composite was applied as an electrode material for the development of a bioanode, which was fabricated by the electrochemical entrapment of ferritin (Frt) as mediator and glucose oxidase (GOx) enzyme in the matrix of the as-synthesized MnO_2-G/PTA deposited on glassy carbon electrode (GCE) surface. It was revealed that this hybrid electroactive support (MnO_2-G/PTA) used for the immobilization of the enzyme (GOx) provides appropriate electrical cabling between the redox enzyme (GOx) and the electrode surface. The as-developed GCE/MnO_2-G/PTA/Frt/GOx bioanode attained a maximum current density of 3.68 $mAcm^{-2}$ at 35 mM glucose concentration at a scan rate of 100 mVs^{-1}. This modified electrode possesses a high potential and good biocompatibility for production of bio-electricity from glucose.

Yaqoob *et al*. [55] used oil palm biomass waste-derived graphene derivatives (L-GO) as an anode in a double chamber of MFCs. This composite based anode (L-GO/ZnO) was fabricated to generate energy and remove Pb^{2+} from wastewater. It was reported that L-GO/ZnO anode showed 91.07% removal efficiency of lead ions, while only 85% removal efficiency was exhibited by L-GO anode. It was found that the composite anode (L-GO/ZnO) showed maximum power density (1350×10^{-3} mW m^{-2}) and current density (142.98 mA m^{-2}), which was relatively

many times higher than the L-GO anode (power density = 20×10^{-3}mW m^{-2} and current density = 17.54 mA m^{-2}).

There are a number of reactions, which involve biotransformations/organic transformations by the biocatalysts. Normally, the activity of an enzyme is limited because of its mobility; therefore, immobilization of such entity is necessary to enhance its activity. Graphene and graphene based materials such as graphene oxide and reduced graphene oxide have a good potential in this respect. These biocatalysts can effectively promote some bioreactions. Other applications of such biocatalyst are biosensors, biofuels, *etc*. It will prove to be a promising area of research in coming decades.

Some recent development in the fields of immobilization of enzymes, biofunctionalization of protein, biosensors, enzymatic biofuel cells, *etc*. have been summarized in Table **1**.

Table 1. Recent applications of graphene- based biocatalayst.

SUPPORT	APPLICATION	REFERENCE
Graphene oxide	Immobilization of Adenylate cyclase	[56]
Reduced graphene oxide	Immobilization of Geotrichumcandidum acetophenone reductase	[57]
Graphene oxide	Functionalized by loading laccase	[58]
Reduced graphene oxide	Biosensor for detection of sarcosine	[59]
N-Doped graphene	High-energy enzyme biofuel cells	[60]
Graphene	Xylose-fueled microbial fuel cells	[61]
Graphene oxide	Adsorption of dyes through immobilized lipase	[62]
Graphene oxide	Biosensor for detection of doxorubicin hydrochloride	[63]

CONCLUSION

There are a number of reactions that involve biotransformations/organic transformations by the biocatalyst. Normally, the activity of an enzyme is limited because of its mobility; therefore, immobilization of such entity is necessary to enhance its activity. Graphene and -based material such as graphene oxide and reduced graphene oxide have a good potential in this respect. These biocatalysts can effectively promote some bioreactions. Other applications such as biosensors, biofuels *etc*. will surface as a promising area of research in the coming decades.

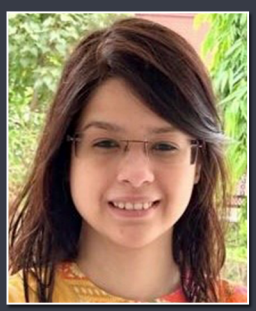
Pinki Bala Punjabi

Prof. Pinki Bala Punjabi obtained her M.Sc., M. Phil. and Ph.D. degrees from Vikram University, Ujjain (M.P.), India. She secured the first position in M.Sc. (1980) as well as in M.Phil. (1981). She has 34 years of research and teaching experience and superannuated from the Department of Chemistry, Mohanlal Sukhadia University, Udaipur (Raj.) in 2019. She is also a lifetime member of various societies namely, the Indian Chemical Society, Kolkata; Indian Council of Chemists, Agra; Indian Science Congress, Kolkata; and Indian Association of Chemistry Teachers, Mumbai. She has published around 139 research papers in journals of international and national repute. She has authored several chapters and books for renowned publishers such as Taylor and Francis, Elsevier, Apple Academic Press, CRC Press, Materials Research Forum, Nova Science Publishers, etc. She is also a reviewer of several international journals. She has completed two major research projects sponsored by University Grants Commission, New Delhi. Prof. Pinki Bala Punjabi has delivered invited lectures and chaired technical sessions at various national and international conferences. She has also organized two national-level conferences. Her expertise includes nanochemistry, particularly graphene chemistry, photocatalysis, organic synthesis, and polymer synthesis.



Rakshit Ameta

Dr. Rakshit Ameta has a first-class career throughout securing the first position in the M. Sc. and was awarded a Gold Medal. He was also conferred Fateh Singh Award by Maharana Mewar Foundation, Udaipur for his meritorious performance. After completing his Ph.D., he served at Hindustan Zinc Limited, Vedanta Group for one year. He has served at M. L. Sukhadia University, Udaipur; University of Kota, Kota, PAHER University, Udaipur, and presently J. R. N. Rajasthan Vidyapeeth (Deemed to be University) Udaipur. 16 Ph.D. students have been awarded their Ph.D. degrees under his supervision in various aspects of green chemistry. He has around 150 research publications to his credit in the journals of national and international repute. He also has a patent to his credit. He is a reviewer of around 50 international journals.

Dr. Rakshit has successfully organized many national conferences at the University of Kota, Kota; PAHER University, Udaipur, and JRN Rajasthan Vidyapeeth, Udaipur. He has delivered invited lectures and chaired sessions at 20 national conferences in different parts of the country. Dr. Rakshit served as a Council Member (2011-2013 & 2020-2022) and an Associate Editor of Physical Chemistry Section (2014-16), a Scientist-in-Charge in the Industrial and Applied Chemistry Section (2014-2016) of the Indian Chemical Society, Kolkata, and an Executive Council Member (2012-2014). He was also a Zonal Secretary (2016-18) of the Indian Council of Chemists, Agra.

He has written books and chapters published by CRC Press (Taylor & Francis), UK; Academic Press, Elsevier; Nova Publishers, USA; and Trans-Tech Publications, Switzerland. In 2017, he received Prof. U.C. Pant Memorial Award instituted by the Indian Chemical Society for his significant contribution. His research specialization includes photochemistry, green chemistry, microwave-assisted reactions, environmental chemistry, waste-water treatment, nanochemistry, solar cells, bioactive and conducting polymers. Recently, he has been elected as the Vice-President of the Indian Chemical Society, India.

Sharoni Gupta

Sharoni Gupta obtained her Ph.D. degree from Mohanlal Sukhadia University, Udaipur (Raj.), India in the year 2020. She was awarded the University Gold Medal for securing the first position in M.Sc. (Chemistry) in the year 2015. She was also a recipient of the Maulana Azad National Fellowship from the University Grants Commission, New Delhi. She has contributed 10 articles and chapters to the journals and books of leading international publishers such as Apple Academic Press, CRC Press, Bentham Science, Elsevier, Springer Nature and Wiley & Sons. Her specialization fields include graphene-based chemistry, nanocatalysis, and sustainable organic synthesis.

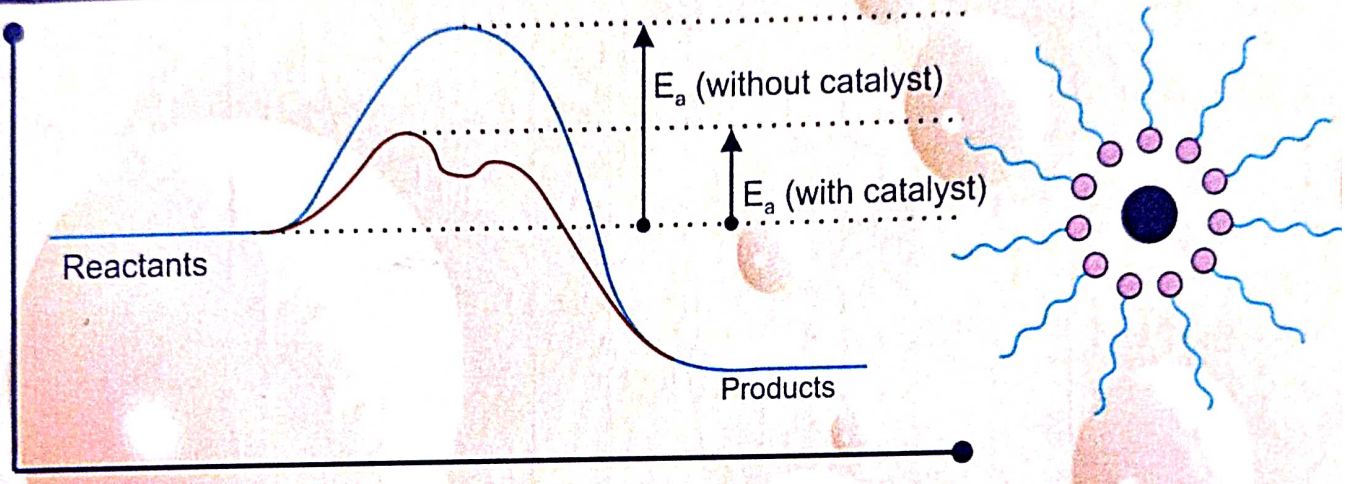
CONTENTS

Sr No	Paper Title	Page No.
1	A Geographal Study of Sex Ratio in Latur **S. B. Ashture**	1-4
2	A Study on Factors Influencing Individual Investment Decisions Towards Indian Share Market **Mrs. Abilasha N, Dr. Madhu Tyagi**	5-11
3	A Relative Study on The Decalogue of Ronald Knox and The Earlier Novels in The Dublin Murder Squad Series of Tana French **Janani P R, Dr. Preetha C**	12-13
4	The Ecocentric Environmental Paradigm In Coehlo's The Alchemist **Mantha Padmabandhavi Prakashrao**	14-17
5	A Study On Environmental Perspectives Of Amitav Ghosh's The Hungry Tide **G. Prema**	18-21
6	Mobile Apps Of Libraries: Boon For Library Users **Dr. Sangaraj Hosamani**	22-25
7	Voices Of The Subaltern Female Protagonist In Vikas Swarup's The Accidental Apprentice **Prashant Jambhulkar, Dr. Vivek V. Joshi**	26-30
8	"A Study Of Modern Teaching Techniques In Acquiring English Language With Global Perspective" **Dr.P.R.V.N.Kesava Kumar**	31-36
9	Study Of Interactions Of 2-{[2-(Cyclohexylcarbamoyl) Benzoyl] Amino}-3-Methylbutanoic Acid (2ca3mba) With Bsa At Different Ph Using Ultrasonic Interferometer And Ft-Ir Techniques **Shrikant B. Thakare**	37-42
10	Effect Of Child Exploitation On The Socio-Economic Status In India **Dr. Sanjay Kumar Das**	43-48
11	Very Rare Sp. Of Odonates (Dragonflies And Damselflies) At Salim Ali Lake (Aurangabad City) **JB Aghade, SA Saraf**	49-52
12	New Media Use By Academic College Librarians To Provide Information To Library Users During Covid-19 Pandemic Period **Amol Bhaudas Meshram, Dr. Kishorsingh R. Chungade**	53-58
13	Skill Impact Bonds In Enhancing Youth Population In India **Kaleeshwari.S, Dr.M. Jegadeeshwaran**	59-61
14	Padmini As An Existential Woman In Girish Karnad's Play Hayavadana **Priti Nilkanth Bhandekar, Dr. Vivek V. Joshi**	62-64



15	The Study On Significance Of Dramatic Techniques In Roy Williams's Depiction Of Realistic Content In Joe Guy **Mr. Samadhan M. Jadhav, Dr. Prabhanjan B. Mane**	65-70

प्रस्तावना

वायु जल भूमि वनस्पति पेड़ पौधे पशु मानव सब मिलकर पर्यावरण बनाते हैं प्रकृति में इन सब की माया और इनकी रचना कुछ इस प्रकार से व्यवस्थित है कि पृथ्वी पर एक संतुलन 20वीं सदी की शुरुआत से पृथ्वी की जलवायु में देखे गए परिवर्तन मुख्य रूप से मानवीय गतिविधियों, विशेष रूप से जीवाश्म ईंधन के जलने से प्रेरित हैं, जो पृथ्वी के वायुमंडल में गर्मी-ट्रैपिंग ग्रीनहाउस गैस के स्तर को बढ़ाता है, जिससे पृथ्वी की सतह का औसत तापमान बढ़ जाता है। इन मानव-उत्पादित तापमान वृद्धि को आमतौर पर ग्लोबल वार्मिंग के रूप में जाना जाता है। आंतरिक परिवर्तनशीलता (उदाहरण के लिए, अल नीनो, ला नीना और प्रशांत डेकाडल ऑसीलेशन जैसे चक्रीय महासागर पैटर्न) और बाहरी बल (जैसे, ज्वालामुखी गतिविधि, सूर्य के ऊर्जा उत्पादन में परिवर्तन, पृथ्वी की कक्षा में बदलाव सहित) जलवायु परिवर्तन में प्राकृतिक प्रक्रियाएं भी योगदान दे सकती हैं।) अतीत, वर्तमान और भविष्य के जलवायु परिवर्तन की निगरानी और अध्ययन के लिए वैज्ञानिक सैद्धांतिक मॉडल के साथ-साथ जमीन, वायु और अंतरिक्ष से टिप्पणियों का उपयोग करते हैं। जलवायु डेटा रिकॉर्ड जलवायु परिवर्तन के प्रमुख संकेतकों का प्रमाण प्रदान करते हैं, जैसे कि वैश्विक भूमि और समुद्र के तापमान में वृद्धि; समुद्र का स्तर बढ़ना; पृथ्वी के ध्रुवों और पर्वतीय हिमनदों में बर्फ की हानि; चरम मौसम में आवृत्ति और गंभीरता में परिवर्तन जैसे तूफान, गर्मी की लहरें, जंगल की आग, सूखा, बाढ़ और वर्षा; और बादल और वनस्पति आवरण परिवर्तन

भूमंडलीय तापक्रम में वृद्धि

ग्लोबल वार्मिंग, मानव गतिविधियों के कारण पूर्व-औद्योगिक काल (1850 और 1900 के बीच) के बाद से पृथ्वी की जलवायु प्रणाली का दीर्घकालिक ताप है, मुख्य रूप से जीवाश्म ईंधन के जलने से, जो पृथ्वी के वायुमंडल में गर्मी-फंसाने वाले ग्रीनहाउस गैस के स्तर को बढ़ाता है। इस शब्द का प्रयोग अक्सर जलवायु परिवर्तन शब्द के साथ एक दूसरे के स्थान पर किया जाता है, हालांकि बाद वाला मानव और प्राकृतिक रूप से उत्पादित वार्मिंग और हमारे ग्रह पर इसके प्रभाव दोनों को संदर्भित करता है। इसे आमतौर पर पृथ्वी के वैश्विक सतह के तापमान में औसत वृद्धि के रूप में मापा जाता है।

पूर्व-औद्योगिक काल के बाद से, मानव गतिविधियों का अनुमान है कि पृथ्वी के वैश्विक औसत तापमान में लगभग 1 डिग्री सेल्सियस (1.8 डिग्री फ़ारेनहाइट) की वृद्धि हुई है, एक संख्या जो वर्तमान में प्रति दशक 0.2 डिग्री सेल्सियस (0.36 डिग्री फ़ारेनहाइट) बढ़ रही

है। यह स्पष्ट है कि मानव प्रभाव ने वातावरण, महासागर और भूमि को गर्म कर दिया है।

ग्लोबल वार्मिंग औद्योगिक क्रांति के बाद से औसत वैश्विक तापमान में वृद्धि को दर्शाता है। 1880 के बाद से औसत वैश्विक तापमान में लगभग एक डिग्री सेल्सियस की वृद्धि हुई है। ग्लोबल वार्मिंग एक सतत प्रक्रिया है, वैज्ञानिकों को आशंका है कि 2035 तक औसत वैश्विक तापमान अतिरिक्त 0.3 से 0.7 डिग्री

बढ़ी हुई वर्षा से कृषि को लाभ हो सकता है, लेकिन एक ही दिन में अधिक तीव्र तूफानों के रूप में वर्षा होने से, फसल, संपत्ति, बुनियादी ढांचे को नुकसान होता है और प्रभावित क्षेत्रों में जन-जीवन का भी नुकसान हो सकता है।

ग्लोबल वार्मिंग के कारण समुद्री सतह का तापमान भी बढ़ जाता है क्योंकि पृथ्वी के वातावरण की अधिकांश गर्मी समुद्र द्वारा अवशोषित हो जाती है। गर्म समुद्री सतह के

23. Role of Innovative Pedagogical Strategies in Education
Dr. Ritu Singh Mahiyaria 241-248

24. Status of Future Challenges of Higher Education in India
Dr. Arun Kumar Mishra, Dr. Santosh Narain Pandey 249-255

25. Student Centered Approaches: The Role and Significance in Today's Academic System
Prof. Iranna Ronad 256-262

26. The Role of Innovative Teaching Methods in Modern Education
Jige Sandipan Babasaheb 263-277

27. Unlocking Work-Life Balance: The POWER-C LIFESTYLE Framework for Teaching Professionals
Akhila Rao, Shailashri V. T. 278-304

28. Ushering Service Learning from the Syllabus to Classroom
Vidya Krishnamoorthy 305-313

29. Vedic to Modernistic-A Study on India and Strategic Way of Inclusive Education
Partha Sarathi Sarkar 314-322

30. समकक्ष आकलन (Peer Assessment)
Dr. Jyotika Kharbanda 323-330

About the Authors

Prof. Shurveer S. Bhanawat has been working as a Professor and Head, Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur. Sixty eight research articles have been published. He was awarded by ICAI international research award in 2021 and 2022.

Dr. Avinash Panwar is currently working as Associate Professor, Department of Comp. Sc., Course Director, Informatics and Computational Sciences Programme, Nodal Officer College of Engineering and Architecture & Director, Computer Center at Mohanlal Sukhadia University, Udaipur.

Dr. Shilpa Vardia has been working as an Assistant Professor in the Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur. She is the convener of the Master of Finance and Control and Post-Graduation Diploma in Taxation Programme. She has contributed thirty-four research papers and also received ICAI International Research award in 2020.

Dr. Shilpa Lodha is Assistant Professor at Department of Accountancy and Statistics, Mohanlal Sukhadia University, Udaipur (Raj). Her more than 25 research papers have been published in journals of national and international repute. She is Convener of B. Com. Honours.

Dr. Asha Sharma is Assistant Professor in the Department of Accountancy and Business Statistics at Mohanlal Sukhadia University, Udaipur. She is the convener of Bachelor of Vocation and Master of Vocation (Accounting, taxation, and auditing). She has contributed more than 85 research papers.

Dr. Parul Dashora is an Assistant Professor in Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur, [RAJ]. She is also Convener of Certification Programmes of the department. She also has two patents to her credit.

Pushpraj Meena is an Assistant Professor in Department of Accountancy and Business Statistics, University College of Commerce and Management Studies at Mohanlal Sukhadia University, Udaipur (Rajasthan). He has 6 years of experience in practical field of Accounting, Auditing and Taxation.

CONTENTS

Chapter	Name of Chapter	Page No.
1	The Study of Micro Finance Related to Government Initiative Mission Mangalam ***Pratik Paun & Prof. (Dr.) Pratapsingh Chauhan***	01-07
2	Factors Affecting the Quality of Work Life of Women Employees: A Study of Small and Medium Enterprises (SMEs) in IT Sector in Rajasthan ***Aparna Soni & Dr. Meera Mathur***	08-20
3	Business Value Development: A Strategic Approach for Business Management ***Rajendra Deshpande***	21-28
4	Corporate Social Responsibility and Consumer Behaviour ***Dr. (Mrs.) Asha Sharma***	29-34
5	Women Empowerment in India: Challenges and Issues ***Dr. Mahesh Singh Rajput***	35-40
6	Hedge Ratio and Hedging Effectiveness Estimates for Stock Futures on NSE India ***Kerkar Puja Paresh & Dr. P. Sriram***	41-48
7	Oil Sector: Current Perspective of India ***CS Pradyumna Sharma & Dr. D.C. Jain***	49-57
8	Devising Suitable Models for Inclusive Finance ***Dr. Nitin Raj***	58-68
9	Issues and Challenges on Infrastructure Sector with Overview on Indian Economy ***Dr. Rohitash Lal Bairwa***	69-74
10	GST: Issues and Impact on Indian Banking Sector ***Dr. Naresh Kumar & Mamta Bhushan***	75-82
11	Bridging the Gender Gap: Empowering Women through Financial Inclusion ***Dr. Shaifali Mathur***	83-96
12	Role of Women Entrepreneurs in Make in India Campaign ***Miss Monika Talreja & Dr. Anurodh Godha***	97-102
13	Karz Mafi (Loan Waivers): Is it the Right Solution to the Woes of Indian Farmers? ***Ms. Pooja Pareek & Dr. R.K. Sharma***	103-106

14	Role of Tourism & Hotel Industry in Development of Jodhpur City (Rajasthan): An Overview ***Dr. Ashok Kumar & Nisha Sankhla***	107-115
15	A Study on Rural Development ***Dr. J. Venugopal***	116-120
16	Aim of Economic Growth and Its Analogous Share in National Economy: With Special Reference to Rajasthan ***Rita Soni***	121-124
17	Fair Value Measurement Concept of IFRS: Problems and Prospects in Corporate Reporting in India ***Manisha***	125-136
18	Role of Literature in Advancing Women's Economic Empowerment ***Dr. Ruchi Goyal***	137-142
19	Merger and Acquisition of Selected Indian Company ***Prof. (Dr). Mahendra H. Maisuria***	143-148
20	Impact of GST on Economy and Marketers in India ***Ms. Chandni Seth***	149-154
21	An Evaluative Study of Microfinance and Women Empowerment in Rajasthan ***Ekta & Salim Khan***	155-160
22	Empowerment of Women: Strategies and Governmental Efforts ***Dr. Piali Biswas***	161-166
23	Government Reforms for Developing Women Entrepreneurs ***Dr. Neha Khatri***	167-182
24	Analysis of Oilseed Crops Scenario in Rajasthan ***Sunil Kumar & Anuj Kumar***	183-191
25	The Amendment in GST: An Attempt to Give Relief to Ordinary Consumer ***Kavita Bharti***	192-198
26	Impact of Demonetization on Society and Economy ***Sunita Sharma*** & ***Prof. D.S. Rathore***	199-201
27	CSR and Sustainable Business Strategies: Global Growth Phenomenon in View of Environmental Concerns ***Dr. Kamlesh Pritwani***	202-206

Contents

1.	Investment perspective of investors in share market-Case study of working women in Udaipur city	
	Prof. P.K.Singh	1
2	Election Tourism in India: A Niche Market to Encash India's Biggest Festival of Worlds Largest Democracy	
	Priyanka Payal	
	Dr. Rajeev K. Saxeena	15
3.	Measuring Effectiveness of Supply Chain Management and Its Impact on Financial Performance	
	Dr. Asha Sharma	25
4.	Impact of Expert System's on Audit Efficiency	
	Pushpraj Meena	
	Dr. Vinod Kumar Meena	38
5.	Implementation of CSR Practices and Challenges in its Development	
	Dr. Raja Bhoj Sharma	
	Nikhar Goyal	51
6.	Artificial Intelligence and Blockchain Technology: A Disruptive integration for Accounting and Auditing Profession	
	Gourav Surana	
	Shurveer S. Bhanawat	60
7.	Carbon Accounting Practices in Select European Companies	
	Neelam Yadav	
	Durga Singh Gour	
	Shurveer S. Bhanawat	68

8. Implementation of IFRS in India as IND AS and Significant Carve-outs
Nikhar Goyal
Dr. Raja Bhoj Sharma 87
9. Revealed Accounting Treatment under Cloud Computing Arrangement
Neelam Yadav
Mukesh Kumar
Shurveer S. Bhanawat 96
10. A Critical Study on Indian Banking System towards Digital Finance and Development of Business in India
Dr. Lokesh Mali 106
11. Challenges and Issues on Implementation and Value Relevance of IFRC (with special reference to Indian Accounting System)
Vikram Singh 112
12. Role of Artificial Intelligence for Agriculture Development: An Emerging Era of Research
Dr. Rakesh Birda 119
13. Study of Factors Influencing Consumer's Online Shopping Behavior with Special Reference to Organized Retail Market
Dr. Abhineet Saxena
Dr. Ashish Sharma 128
14. Readiness Indices for Adoption for Industry 4.0
Dr. Narendra Goyal 147
15. Digital Transformation and User's Awareness & Attitudes towards Artificial Intelligence Technology in the Banking Industry
Dr. Renu Sharma
Neha Khandelwal 155
16. Comprehensive Analysis of E-Commerce in India
Dr. Rajesh Meena
Dr. Manish Dadhich 170
17. Prospect of Micro Finance in Entrepreneurship Development in Zambia
Robert Mwiinga
Dr. Manish Dadhich 181

18. Marketing of Information Products and Services in the Electronic Era
Dr. Surendra Sethy 194
19. Challenges and Issues on Implementation and Value Relevance of IFRC With Special Reference to Indian Accounting System
Dr. Y. R. Goswami 204

About the book

Description

Plant-Microbe Interaction - Recent Advances in Molecular and Biochemical Approaches: Agricultural Aspects of Microbiome Leading to Plant Defence, Volume Two continues the work of Volume One, covering the role of these plant microbes and their interaction between plants and microbes. These beneficial microbes, such as bacteria and fungi are also known as plant growth-promoting

Show more

Key Features

- Covers agricultural aspects in which the biochemistry in between plants and microbes helps us understand interactions in the rhizosphere
- Helps readers understand the molecular and biochemical approaches of plant-microbe interactions

Description

Plant-Microbe Interaction - Recent Advances in Molecular and Biochemical Approaches: Overview of Biochemical and Physiological Alteration During Plant-Microbe Interaction, Volume One covers the role of these plant microbes and their interaction between plants and microbes. These beneficial microbes, such as bacteria and fungi are also known as plant growth-promoting

Show more

Key Features

- Covers agricultural aspects in which the biochemistry in between plants and microbes helps us understand interactions in the rhizosphere
- Helps readers understand the molecular and biochemical approaches of plant-microbe interactions

Herd Behaviour: A Psychological Bias of Behavioural Finance Theory

Dr. Shilpa Lodha[1] | Charu Sharma[2]

ABSTRACT:

This paper provides a detailed description of the herd behaviour, one of the emotional biases of behavioural finance theory. Due to the challenges and contradictions faced by efficient market hypothesis, behavioural finance has become a very important research field. Various authors have contributed in the field of behaviour finance theory so the present study is focused on the concept of herd behaviour, its evolution, causes, types and relevance of further research in the field of herd behaviour. The paper has concluded that herd behaviour could be of great relevance in the stock market as the same has been observed as most common psychological bias among all other anomalies.

I.INTRODUCTION

Investment decisions are vital for the success and survival of an investor. When an individual decides and invests his sum of money, he becomes investor. Individual investors accumulate their savings and convert them into investments. Institutional investors try to earn maximum returns by investing their idle funds. Investment helps in protecting the value of money which an individual possesses as the value of money decreases with the passage of time due to inflation effect. An investor is required to invest their money in such a way so that he should be able to earn such rate of return which is greater than the inflation rate. Therefore, investors need to analyze the investment

Crowdfunding: A Conceptual Understanding

Dr. Shilpa Lodha[1] | Babu Lal Gedar[2]

ABSTRACT

Crowdfunding (CF) is an emerging platform for financial help and a new way to collect money. It's a good medium of financial assistance for any person, an organization, NGO, new startups and others. In this paper, one would get to know about a conceptual understanding of crowdfunding. Aim of the study is to explore conceptual framework of crowdfunding and it covered introduction, history and types of crowdfunding, legal framework of crowdfunding in India and other countries, process of generating fund from crowdfunding, benefits and challenges of crowdfunding. It is concluded that crowdfunding is growing very fast in many countries whereas in India there is a need to spread more awareness about it.

Keywords: *Crowdfunding, Equity Crowdfunding, Debt Crowdfunding*

INTRODUCTION

In finance, procuring funds is the basic step for investment and distribution decisions. Of late,crowdfunding is emerging as an alternative way of procuring funds for start-ups and entrepreneurial projects. Several authors have tried to define crowdfunding.

"Crowdfunding is solicitation of funds (small amount) from multiple investors through a web-based platform or social networking site for a specific project, business venture or social cause." (SEBI Consultation Paper, 2014)[1].

Crowdsourcing occurs when a profit-driven company outsources specific tasks critical to the production or sale of its product to the general public (the crowd)

Impact of XBRL Reporting System on the Reliability of Financial Reporting in India

Apporva Mamodiya[1] | Dr. Shilpa Lodha[2]

ABSTRACT

XBRL is a very dynamic and modern financial reporting language which is being used around the world to communicate the results of operational and financial performance of the business organisations. It ensures accuracy, reliability, timeliness and decision usefulness to various stakeholders. This paper focuses on the impact on the XBRL reporting on the reliability and transparency of the financial reporting system in India. The data was obtained through a questionnaire survey of 34 accounting professionals. Collected data was analysed with the help of descriptive statistics and concludes that XBRL reporting positively impacts on the reliability of financial reporting system in India. It is also assumed that the use of XBRL will provide stakeholders and recipients of the financial statements with financial information about the companies that are credible.

Keywords: *XBRL, Financial reporting, Reliability, Transparency.*

INTRODUCTION

XBRL is a state-of-the-art tool for digitized disclosure of business and financial information ofbusiness houses. And this is the emerging reporting trend around the world. This new tool removes almost all the disadvantages of traditional formats of financial reports like paper- based, PDF, HTML, Word etc., these are static in nature which does not enable the preparers and users to easily compare, analyse and reuse past reports to prepare reports for the current years. But Extensible Business Reporting Language benefits both the creators and the

MYCOTOXINS IN FOOD AND FEED

Detection and Management Strategies

Mycotoxins represent an assorted range of secondary fungal metabolites that extensively occur in numerous food and feed ingredients at any stage during pre- and post-harvest conditions. Mycotoxin contamination in food and feed cause acute and chronic mycotoxicosis, including teratogenic, carcinogenic, oestrogenic, neurotoxic, and immunosuppressive effects and several others health issues. ***Mycotoxins in Food and Feed*** presents an overview of all the major mycotoxins, sources of production, chemistry and biosynthesis, occurrence in food and feed, effect on agriculture, effect on human health, detection technique, masked mycotoxins, and management and control strategies.

Key Features

- Provides broad coverage of mycotoxins and their effects on food and feed
- Includes comprehensive information of occurrence, chemistry, detections methods and management strategies for each toxin
- Discusses recent development in detection technologies for major mycotoxins
- Explores agricultural practices and post-harvest management strategies for managing mycotoxin infestations

ABSTRACT

The long and continuous ice cores obtained from drilling thick ice sheets of Antarctica provide us with one of the best high-resolution records of climate change during the last 800 kilo years. Away from anthropogenic activities, the ice core records are relatively uncorrupted and well preserved. The interior of Antarctica becomes still far away from the moist warm climate of the coastal region further reducing the moisture transport due to continentality. Despite being so dry, the desert continent holds 70% of the freshwater of the Earth. Much of the early history of the Antarctic ice sheet is revealed not from Antarctica but from the marine sedimentary record in the Southern Ocean surrounding Antarctica. However, for the last few thousand years, several ice cores reveal a direct record of Antarctic climate. The history of origin and subsequent permanent establishment of the Antarctic ice sheet has been well constrained by the oxygen isotope record of the benthic foraminifera from the marine sediments.

अंधेरों से संघर्ष करता एक उपेक्षित दिया : 'यमदीप'

डॉ. नीता त्रिवेदी

हमारी दुनिया के समानांतर चलती एक उपेक्षित दुनिया जो हमारे आसपास होते हुए भी, नजरों से दृष्टिगत होते हुए भी, हमारे दृष्टिकोण का हिस्सा नहीं बन पाती। यह दुनिया हमारे आसपास चलते-रहते-जीते नजर तो आती है पर हमारे विचारों तक उस दुनिया की पहुंच नहीं है। हां, एक पूरी की पूरी दुनिया हमारे आसपास ताली बजाती हुई, हमारे मांगलिक उत्सवों पर खुशियां मनाते हुए दुआएं देती और नेग लेकर गाती बजाती हमारे आसपास चलती है, किंतु यह हमारे लिए केवल भय, कौतूहल और घृणा का ही भाव उत्पन्न करती है विमर्श का नहीं। जी हां मैं बात कर रही हूँ– किन्नर समाज की जो सदियों से उपेक्षित, संघर्षशील रहा है। इस समाज में रहता हुआ समाज से दूर। यह समाज सृष्टि की उत्पत्ति से ही हमारे मध्य रहा है। सभ्यता के विकास के साथ मानव ने कई स्तरों पर उत्तरोत्तर प्रगति की है किंतु यह समाज आज भी अपनी अस्मिता के लिए संघर्षरत है। विमर्श के इस दौर में किन्नर विमर्श पर भी साहित्य ने सुधि ली है जिस कारण से इनके जीवन संघर्ष, यातनाओं-भावनाओं आदि ने बौद्धिक मानस पर अपनी उपस्थिति दर्ज करवाई है।

साहित्य में किन्नर विमर्श पर नीरजा माधव कृत 'यमदीप' उपन्यास भारतीय हिंदी साहित्य में अब तक ज्ञात प्रकाशित उपन्यासों में पहला उपन्यास माना जाता है। समकालीन स्त्री साहित्यकारों में नीरजा माधव एक सशक्त नाम है। आपने कथा साहित्य एवं कथेतर गद्य साहित्य में अपनी लेखनी द्वारा एक अलग विशिष्ट पहचान बनाई है। आपने समसामयिक विषयों पर गंभीर चिंतन प्रस्तुत किया है। आपके कहानी संग्रह हैं- 'चिटके आकाश का सूरज', 'अभी ठहरो अंधी सदी', 'आदिम गंध तथा अन्य कहानियां', 'चुप चंतारा रोना नहीं', 'पथदंश', 'वाया पांडेपुर चौराहा'। आप के प्रसिद्ध उपन्यास हैं - 'यमदीप', 'तेभ्यः स्वध', 'ईहानृग', 'अवर्ण महिला कॉन्स्टेबल की डायरी', 'अनुपमेय शंकर', 'गेशे जम्पा', 'मृगदाय के अहेरी', 'धन्यवाद सिवनी', 'रात्रिकालीन संसद'। आपके निबंध संग्रह हैं- 'चौत चित मन महुआ', 'रुकोगी नहीं भागीरथी', 'सांझी फूलन चिति', 'यह राम कौन है'? 'प्रस्थानत्रयी' नाम से आपका एक काव्य संग्रह भी प्रकाशित हुआ है। आपका रचना कर्म आपकी बहुमुखी प्रतिभा को अभिव्यक्त करता है। आपकी औपन्यासिक कृति 'यमदीप' सन 2002 में प्रकाशित उपन्यास है। यह उपन्यास किन्नर समाज एवं स्त्री अस्मिता पर आधारित एक महत्वपूर्ण हस्ताक्षर है।

'यमदीप' उपन्यास का शीर्षक ही पाठक को कथा की मूल संवेदना से सराबोर कर देता है। 'यमदीप' अर्थात यम के लिए जलाया गया दीप। प्रकाश-पर्व की पूर्व संध्या पर घर से बाहर घूरे (कूड़ा करकट की जगह) पर यमदीप रखा जाता है। इस दीप की कोई पूजा-अर्चना, आरती कुछ नहीं होती। यहां तक की उस दीप को रखने के बाद पलट कर उस ओर भी नहीं देखा जाता। ऐसा उपेक्षित दीप यमदीप है जो उस सांध्य कालीन घनघोर अंधेरे से अकेला ही संघर्ष करता है। प्रकाश का नन्हा स्त्रोत उस गहन अंधकार में भी कई पथिकों को मार्ग दिखाता किंतु स्वयं में अकेला जलता रहता है।

नीरजा माधव अपने उपन्यास 'यमदीप' की भूमिका में स्पष्ट लिखती है- "प्रकाश-पर्व की पूर्व संध्या में दरवाजे के बाहर रात-भर टिमटिमाते उसी यम दीपक की भांति जो उपेक्षित होते हुए भी याद दिलाता है

आलोकित कल का। नहीं छूटती उसकी प्रदीप्त होने पर फुलझड़ियां और पटाखे, नहीं होती पूजा अर्चना या चढ़ते थाल पर भोग, पर काली रात के विरोध में टिमटिमाता रहता है चुपचाप, निःशब्द। सूखता रहता है अंतसरस बँद- बँद -बँद।"[1] यदि इस 'यमदीप' के आलोक में हम महताब गुरु, नाजबीबी, छैलू, चमेली, शबनम, अकरम, मंजू आदि को प्रतीकार्थ में देखें तो इस शीर्षक की सार्थकता, उसकी संवेदना को उसकी व्यापकता में देख पाएंगे। क्या यह सभी वह यमदीप नहीं जो अपने घर के बाहर घूरे पर छोड़ दिए गए हैं और परिवार का कोई सदस्य मुड़कर उस दिए को नहीं देख सकता क्योंकि वह दिया अभिशप्त है। परिवार का कोई सदस्य पीछे मुड़कर फिर कभी नहीं जान पाता या जानना चाहता है कि वह दिया उस कूड़े करकट भरी दुर्गंध युक्त उपेक्षित एवं गहन अंधकार में जल भी रहा है या बुझ गया है। दिये का संघर्ष उसका नितांत वैयक्तिक बन जाता है। 'यमदीप' किन्नरों के जीवन को उसकी व्यापकता, गहराई एवं संपूर्णता में व्यक्त करता एक जीवंत दस्तावेज है।

'यमदीप' में नाजबीबी तथा मानवी की कथा दो समानांतर ध्रुवों पर चलती है। नीरजा जी 'यमदीप' की भूमिका में ही मानवी के संबंध में स्त्री विमर्श का एक नया आयाम प्रस्तुत करती है– "मानवी का पूरा का पूरा स्त्री विमर्श है। अपनी अस्मिता और स्वीकार के लिए एक अंतहीन जिजीविषा लिए। आदर्श भारतीय स्त्रीत्व-गरिमा की राह से एक पग भी लड़खड़ाए बिना। पितृसत्ता के सह-अस्तित्व को बिना नकारे, अपने अस्तित्व के लिए पूर्णतया चौतन्य। स्त्री के संघर्षों और जुझारूपन को तथाकथित नारी-मुक्ति आंदोलन की आयातित दृष्टि से नहीं, बल्कि अपने बौद्धिक और तार्किक दृष्टिकोण से जांचती-परखती, पर सहानुभूति के स्थान पर स्वानुभूति से तथ्यों तक पहुंचने के बाद ही कोई निर्णय लेती हुई।"[2] मानवी उपन्यास में एक संवेदनशील पत्रकार है जो वंचितों एवं शोषितों के प्रति सहानुभूति रखते हुए उनके उद्धार के लिए प्रयत्नशील दिखाई पड़ती है। वह पारिवारिक एवं सामाजिक स्तर पर संघर्षशील रहते हुए स्त्री-अस्मिता के प्रति जागरूक नारी है।

नाजबीबी उर्फ नंदरानी भी अपने अस्तित्व के प्रति संघर्षशील, भावुक, मानवीय गुणों से ओतप्रोत, संवेदनशील किंतु सर्जक एवं सुदृढ़ व्यक्तित्व की किन्नर है। उपन्यास के प्रथम अध्याय से ही उसके भावुक मन की झलक मिल जाती है। प्रसव पीड़ा से तड़पती एक पगली स्त्री को जब गली- मोहल्ले के लोग तमाशबीन बनकर देख रहे थे। स्त्रियां अपने घरों से छुप-छुप कर देख रही थी। जब कोई भी उस स्त्री की मदद को नहीं आता तब नाजबीबी अपने साथियों के साथ वहीं उसका प्रसव कराती है। प्रसव पीड़ा से जब उस पगली की मृत्यु हो जाती है और कोई भी उसकी सद्य:जात पुत्री को नहीं अपनाता तब नाजबीबी उसे अपने साथ ले आती है। उसके साथी जब उसे लड़की को साथ ले चलने के लिए मना करते हैं तब वह कहती है– "किसके भरोसे छोड़ें वह बच्ची को? कोई पालने को तैयार नहीं। ऐसे छोड़ देने पर कहीं कुत्ते-कौवे नोंचकर... नहीं... नहीं।"[3] थोड़ी आनाकानी के बाद मेहताब गुरु उस बच्ची को नाजबीवी के साथ रहने की इजाजत दे देते हैं तथा सभी को यह हिदायत भी देते हैं कि बस्ती के बाहर किसी को भी पता ना चले कि यहाँ टेपकी (लड़की) पल रही है।

बच्ची का नाम 'सोना' रखा गया तथा नंदरानी अर्थात नाजबीवी सोना की मां बन जाती है। किन्नरों के मन की ममता, उनकी भावना, उनका मानवतावादी स्वरूप पाठकों को उनके प्रति एक नई दृष्टि देता है। वे अपने परिवार एवं समाज से कटकर अपना एक नया समाज बनाते हैं जहां मानवीय समाज की घृणा, उपेक्षा, तिरस्कार के बदले भी वे उनके प्रति अमानवीय तथा क्रूर नहीं हो सकते। नाजबीबी सोना को बड़े यत्न से पालती है तथा उसे उसी सभ्य समाज के मध्य रहने के लिए, उस के उत्थान के लिए उसे स्कूल में भी भेजती है। वह जब सोना के एडमिशन के लिए स्कूल जाती है तब चपरासी, शिक्षिकाएं तथा प्रिंसिपल तक उस पर व्यंग्य करती है, उसका मजाक बनाती है। सब कुछ होते हुए भी वह सोना को स्कूल भेजती है किंतु सोना को स्कूल में उसके किन्नर होने पर शर्मिंदा ना होना पड़े इसलिए वह छैलू किन्नर जो पुरुष ही लगता है उसे सोना को स्कूल लाने एवं छोड़ने के लिए भेजती है।

इस प्रसंग के माध्यम से लेखिका यह भी बताना चाहती है कि इसी कारण किन्नर जो कि मुख्यधारा में आने का प्रयास भी करना चाहते हैं, समाज के अन्य वर्गों की तो बात ही क्या शिक्षित एवं बौद्धिक वर्ग ही उन्हें हीनता का बोध कराते हैं। नाजबीबी को कभी-कभी अपना अतीत भी याद आ जाता है। वह सोचती है कि समाज के इन्हीं तानों एवं तिरस्कार के कारण उसे आठवीं कक्षा के बाद स्कूल छोड़ना पड़ा था। वह पढ़ना चाहती थी, आगे बढ़ना चाहती थी किंतु सामाजिक उपेक्षा एवं परिवार की बदनामी के डर से उसे स्वयं ही अपना घर छोड़कर किन्नरों की बस्ती में आना पड़ा क्योंकि उसे लग रहा था कि उसके कारण उसकी बड़ी बहन के विवाह में अड़चन आ रही हैं, उसके पिता को समाज में अपमानित होना पड़ रहा है। इन्हीं सब कारणों से नंदरानी स्वयं ही घर छोड़कर चली जाती है। लेखिका ने परत-दर-परत टूटते नंदरानी के मन को बड़ी ही संवेदना से उकेरा है साथ ही उतनी ही क्रूरता से समाज का घृणित चेहरा भी रखा है। कैसी विडंबना है जहां किसी किन्नर को उसका परिवार अपना रहा है, शिक्षा के द्वारा उसकी उन्नति के मार्ग खोलना चाहता है वहां सामाजिक विभेद उसे अवनति के गर्त में ढकेल देता है। नंदरानी के माता-पिता बच्ची को तब भी नहीं छोड़ते। वे नंदरानी का पता प्राप्त कर एक बार उस बस्ती में भी जाते हैं जहां उनकी नंदरानी जो अब नाजबीबी बन चुकी है, रहती है। मां तो नंदरानी की स्थिति देखते ही बेहोश हो जाती है पिता भी आंसू बहाते हैं। वे नंदरानी को वहां से निकाल कर कहीं पक्का घर बना कर देना भी चाहते हैं पर मजबूरी यह भी है कि वे नंदरानी को साथ नहीं ले जा पाते। नंदरानी के भाई-भाभी उसकी उपस्थिति उनके घर में नहीं चाहते। तब सभी किन्नर भावुक हो जाते हैं उन्हें लगता है कि किसी के माता-पिता तो उन्हें मिलने आए वरना कईयों के तो माता-पिता ने हीं उन्हें यहां छोड़ दिया था। इस स्थिति में हिजड़ों के गुरु मेहताब गुरु नंदरानी के पिता को समझाते हुए तथा वास्तविक स्थिति का बोध कराते हुए किन्नर जीवन की त्रासदी को, उनके दर्द को बयां करते हुए कहते हैं– "आप इस बस्ती में रह नहीं सकते बाबूजी, और अपनी बेटी को अपने साथ रख भी नहीं सकते... दुनिया में बदनामी और हँसी-हँसारत के डर से। हिजड़ी के बाप कहलाना न आप बर्दाश्त कर पाएंगे और ना आपके परिवार के

लोग। लूली- लंगड़ी होती यह, कानी-कोतर होती, तो भी आप इसे अपने साथ रख सकते थे... इसीलिए इसे अब इसके हाल पर छोड़ दीजिए। यही उसका भाग्य था, यही बदा... था। सोच लीजिए, मर गई, सब्र कर लिया।"[4]

नाजबीबी उनके साथ नहीं जाती किंतु जब उसे पता चलता है कि उसकी मां की तबीयत बहुत खराब है। उसका अंतिम क्षण निकट आ गया है। तब वह अपने आप को नहीं रोक पाती। बस्ती में बिना किसी को बताए वह अपनी मां से मिलने जाती है। रास्ते में पता लिखा कागज भी उड़ जाता है तब उसकी संवेदनाएं और मुखर हो जाती है। किसी तरह घर पहुंचने पर उसे पता चलता है कि मां की मृत्यु हो गई है तब वह शोक विह्वल हो श्मशान पहुंचती है। यह प्रसंग भी नीरजा जी ने इतना मार्मिक बनाया है जिसे पढ़कर पाठकों का दिल भी पसीजने लगता है। नाजबीबी का अपने पिता के गले लग कर रोना, भैया का समाज के समक्ष उसे अपमानित एवं तिरस्कृत करना और पिता की व्यथा तथा उसका पुनः डेरे की ओर लौटना।

उसके पश्चात नाजबीबी अपनी ममता और प्रेम का पूरा कोष सोना पर लुटाती उसी को अपना जीवन मान पूर्ण तन्मयता से उसके लालन-पालन में जुट जाती है। बस्ती में सभी का सहयोग और महताब गुरु के संरक्षण में सोना बड़ी होने लगती है। एक दिन बस्ती के बाहर कोने का एक डॉक्टर पुलिस को खबर कर देता है कि हिजड़ों की बस्ती में एक लड़की पल रही है। उसके बाद पुलिस वाले हिजड़ों की बस्ती में जाकर सब को धमकाते हैं उन्हीं के दबाव में आकर नाजबीबी को सोना को नारी उद्धार गृह में छोड़ना पड़ता है। नारी उद्धार गृह की संरक्षिका रीता देवी पुलिस एवं नेताओं के साथ मिलकर आश्रम की बालिकाओं का दैहिक शोषण करती है। नाजबीबी को जब आश्रम की स्थिति का वास्तविक परिचय अखबारों के माध्यम से पता चलता है तब वह मानवी की सहायता से सोना को वहां से निकाल पाती है। साथ ही वह इस पूरे घटनाक्रम में मानवी पर नेताओं के तथा पुलिस के दबाव से हमला भी होता है। नाजबीबी उस परिस्थिति में मानवी के जीवन को बचाते हुए उसे हॉस्पिटल भी लेकर जाती है। मानवी के माध्यम से ही आश्रम की बालिकाओं की स्थिति का पता चलता है

कि किस प्रकार कोई लड़की अपने घर की दहलीज को चाहे वह किसी भी कारण से हो, लांघे तो वह पुनः अपने घर नहीं जा पाती। समाज के डर से माता-पिता भी उसे वापस नहीं ले जाते और इस प्रकार शोषण के चक्र में पिसते रहना उनकी नियति बन जाती है।

'यमदीप' उपन्यास में लेखिका ने हिजड़ों के जीवन पर, उनके रीति-रिवाजों आदि पर संपूर्ण प्रकाश डाला है। लेखिका हिजड़ों के समाज से अलग-थलग रहने, उनके मुख्य धारा से ना जुड़ पाने के साथ उनके सामाजिक स्तर पर भी चर्चा करती है। उनकी आय का मुख्य साधन मांगलिक अवसरों पर नाचना गाना, बधाई मांगना है। यजमान द्वारा जो मिल जाए उसी पर उन्हें आश्रित रहना पड़ता है। समाज के आधुनिकीकरण से इन पर आर्थिक संकट आ रहा है। इसके अतिरिक्त रोजगार इन्हें कोई देता नहीं अतः मजबूरन इन्हें देह व्यापार, भीख, डराकर लूटना आदि कृत्य करने पड़ते हैं। इसी संदर्भ में लेखिका कहती हैं– "धंधों में आ रही इस गिरावट को देखते हुए गिरिया रखने तक की छूट तो अब ना चाहते हुए भी स्वीकृति पा चुकी थी उनकी बस्ती में। समलैंगिक भूख से बेचैन कोई-कोई समर्थ पुरुष जो इसका कोती (स्त्री वेशधारी हिजड़ा) के रूप में भरण पोषण कर सके, इसके लिए अपनी इच्छित या अनिच्छत स्वीकृति कोई भी हिजड़ा दे सकता था। पेट पालने की इसी विवशता में कितने तो छिपे मुंदे तौर पर इसे वेश्यावृत्ति की तरह अपना चुके थे, क्योंकि एक तो गिरिया कम लोग बनते थे और दूसरे केवल गिरिया द्वारा दी गई सीमित धनराशि में इनका खर्च चलना मुश्किल हो जाता था। कभी-कभी ट्रेनों और बसों में चढ़कर भी यह धन उगाही करने लगते, लेकिन ऐसे हिजड़ों का पता चलते ही उन्हें बिरादरी से बहिष्कृत करने जैसा दंड भी गुरुजी द्वारा दे दिया जाता क्योंकि उनके समुदाय में भीख मांगना, चोरी हिंसा करना भयंकर पाप माना जाता है।"[5]

आर्थिक स्तर पर विपन्न होने के बावजूद भी देशभक्ति, धर्मनिरपेक्षता आदि पर उनके विचार उन्हें और भी महान बना देते हैं। नाजबीबी मानवी के प्रश्न के जवाब में कहती है– "अपने देश के लिए तो देखिए, हम लोग मर मिटेंगे। जिस तरह फौज में एक सिपाही भर्ती होता है, पुलिस होता है

...सरकार हमें भी हथियार दे दे। मैं तो लड़ूँगी। लड़ते-लड़ते हिंदुस्तान के पीछे अपना जान दे दूँगी। बस, मेरी यही तमन्ना है। मैं मेजर की लड़की हूँ, मेजर की।"[6] उनकी इसी भावना एवं विचारों को देखते हुए मानवी अंत में नाजबीबी का संकल्प उनके चुनाव में खड़े होने को मानती है। और नाजबीबी देश हित के लिए तत्पर मानवी को कहती है – "जैसा कहोगी, मेम साहब, वैसा ही होगा। जैसा भी काम होगा, मैं जनता की भलाई के लिए करूंगी, क्योंकि अपने तो आगे पीछे कोई नहीं है जिसके लिए दूसरों की रोटियां छीनूँगी और अपना घर भरूंगी। जरूरत पड़ी तो भ्रष्ट लोगों के खिलाफ हथियार भी उठाऊंगी। हर गंदगी को जड़ से साफ कर दूँगी। दुनिया में शांति रहे, और क्या चाहिए किसी को?"[7]

नीरजा जी ने 'यमदीप' में किन्नरों के रीति-रिवाज उनकी भाषा-शैली पर विस्तार से वर्णन किया है। नाजबीबी मानवी को बताती है कि – "हम लोगों की एक बेसरा माता है यानी हिजड़ों की देवी। उनका मंदिर अहमदाबाद में है। वहीं गुजरात में। तो वर्ष में एक बार वहां हम सब लोग जुटते हैं। भंडारा करते हैं, नाचते गाते हैं। यानी एक साथ दो चार दिन रहते हैं। हर जिले में हम लोगों के एक गुरु होते हैं। हम लोग जो रोज,कमाई करते हैं, उसका एक बड़ा हिस्सा बेसरा माता के नाम पर गुरुजी के पास जमा करते जाते हैं। उसी में से सब मिलाकर हो जाता है।"[8] हिजड़ों की अपनी एक सांकेतिक भाषा होती है। प्रतीकात्मक एवं संकेत भाषा के प्रयोग द्वारा लेखिका शिल्प को विशिष्टता प्रदान करती हैं। डॉ. विजेंद्र प्रताप सिंह ने अपने लेख में इसे स्पष्ट किया है – "नीरजा माधव ने 'यमदीप' में से चाय के लिए भांपकी, रिक्शा के लिए लुढ़कनी, ढोल के लिए डामरी, लड़की के लिए टेपकी, घुंघरू के लिए छमकने, पुरुषवेश के लिए कड़े ताल में, पिता के लिए सुड्डा, माता के लिए सुड्डी, सौ रुपये के नोट के लिए बड़मा, रखैल हिजड़ा के लिए कोती, किसी को टालने के लिए चिस्सेर पतवाईदास आदि शब्द इनके दैनंदिन भाषा का हिस्सा है जिसे लेखिका नीरजा माधव ने पूरी खोजबीन के साथ प्रस्तुत किया है। हिजड़ों की अनेक सांकेतिक भाषा जैसे– सेवा-समाखन, निहारन, वीला, पानकी, कातका, धौंकनी आदि अनेक नए शब्दों से लेखिका रूबरू करवाती हैं।"[9]

इस प्रकार यह उपन्यास किन्नरों के उदात्त चरित्र, संवेदनशील मन, कर्तव्यबोध, उनकी मानवता, नैतिकता अपने समाज के प्रति उनकी कौटुंबिक भावना, राष्ट्रप्रेम तथा अपनी आराध्या बेसरा माता और अपने हिजड़ा गुरु की आज्ञा पालन सभी से पाठकों का विस्तार से परिचय कराता है। 'यमदीप' इस उपन्यास के अंत में पथ प्रदर्शित करने वाले आलोक का प्रतिनिधि बनकर उभरता है। यही इस उपन्यास का मूल संदेश है।

पवन करण की कविताओं में प्रतिबिम्बित नारी

—डॉ० नीता त्रिवेदी

पवन करण आधुनिक हिंदी कविता के महत्त्वपूर्ण हस्ताक्षर हैं। आपकी कविताएँ दर्शन, समाज, राजनीति, पुराख्यान, जीवन के प्रत्येक क्षण, मानव मन की सूक्ष्म भावनाओं को जिस सहजता से अभिव्यक्त करती हैं उसमें प्रत्येक व्यक्ति अपने मन का दर्शन बड़े ही निश्चल भाव से कर पाता है। यह आपकी लेखनी की महत्त्वपूर्ण उपलब्धि है जो व्यक्ति से उसके ही मन का साक्षात्कार निर्विकार भाव से करा पाता है। आप की कविताएँ व्यक्ति के मन का वह दर्पण है जहाँ वह अपनी सभी सूक्ष्मातिसूक्ष्म मनोभावों के साथ नितान्त एकाकी खड़ा है। मन का दर्पण केवल उसके बाह्य आवरण को ही नहीं, मन की परतों के नीचे दबे छिपे सभी भावों का अपने नग्न रूप में दर्शन कराता है। व्यक्ति ना तो अपनी आँखें बन्द कर उस दर्पण से दूर जा सकता है और न ही सहज भाव से अपने ही मनोभावों से नजरें हटा सकता है। पाठक केवल तिलमिलाकर, बड़ी बेचैनी के साथ मूक दृष्टा बन उन सभी भावों के सामने खड़ा बेबस सा दिखाई पड़ता है।

पवन करण की कविताओं में स्त्री जीवन, उसके मन के विविध भावों, अनुभावों, संघर्षों तथा अभावों की सहज अभिव्यक्ति है। पवन करण की कविताओं में स्त्री मन अपने सभी द्वन्द्वों, संघर्षों, आत्मविश्वास, आस्था, जीवन मूल्यों के साथ मुखरित हुआ है।

18 जून, 1964 ई. को ग्वालियर (म.प्र.) में जन्मे पवन करण समकालीन कविताओं के एक सशक्त हस्ताक्षर हैं। आपने जनसंचार एवं मानव संसाधन विकास में स्नातकोत्तर की उपाधि प्राप्त की। आपके 8 काव्य-संग्रह प्रकाशित

हैं—'इस तरह मैं', ''स्त्री मेरे भीतर'', 'अस्पताल के बाहर टेलीफोन', 'कहना नहीं आता', ''कोट के बाजू पर बटन'', 'कल की थकान' और 'स्त्री शतक' (दो खंडों में)। आपका कविता संग्रह ''स्त्री मेरे भीतर'' मलयालम, मराठी, उड़िया, पंजाबी, उर्दू तथा बाँग्ला में प्रकाशित हो चुका है। इस संग्रह की कविताओं का नाट्यानुवाद एवं मंचन भी हो चुका है। आपकी कविताओं का भारतीय भाषाओं के अतिरिक्त रूसी और अंग्रेजी में भी अनुवाद हुआ है।

आपने नवभारत ग्वालियर में साहित्यिक पृ. 'सृजन' का 5 वर्षों तक संपादन किया। नई दुनिया में साहित्य पर केन्द्रित साप्ताहिक स्तंभ 'शब्द प्रसंग' का लेखन भी आपने किया। आपको अपनी साहित्यिक कृतियों के लिए कई सम्मान भी मिले हैं—'इस तरह मैं' पर रामविलास शर्मा पुरस्कार (म. प्र. साहित्य अकादमी 2000) एवं रजा पुरस्कार (म.प्र. कला अकादमी 2002) प्राप्त हुआ।''स्त्री मेरे भीतर'' पर वागीश्वरी सम्मान (म.प्र. हिंदी साहित्य सम्मेलन 2004), मास्को (रूस) का पुश्किन सम्मान (भारत मित्र समाज, मास्को 2006), शीला सिद्धांतकर स्मृति सम्मान (राग विराग कला केन्द्र, दिल्ली 2007), परम्परा ऋतुराज सम्मान (परम्परा, दिल्ली 2009), केदार सम्मान (केदार शोध संस्थान, बाँदा 2012) तथा स्पन्दन सम्मान आदि अनेक सम्मान आपको मिले हैं।

पवन करण की कविताएँ जीवन की कविता है, जहाँ जीवन का प्रत्येक क्षण, मानव मन की सूक्ष्म भावनाएँ अपनी सहजता में परिव्याप्त है। ये कविताएँ जीवनानुभवों के उस प्राकृतिक सोते के समान हैं जो अपनी राह स्वयं बनाता, उन सभी अनगढ़ रास्तों के बीच से सहज ही निर्बाध गति से आगे बढ़ता चलता है। उनकी कविताएँ अभिधा में हमसे बात करती है, बिना किसी लाग लपेट के। पवन करण का कविता संग्रह 'अस्पताल के बाहर टेलीफोन' के फ्लैप पर उद्धृत पंक्तियाँ भी इसी को स्पष्ट करती है—''ये कविताएँ उन्हीं लोगों के शब्दों और मुहावरों में बात करती हैं जिनकी ये कविताएँ हैं यानी हम और आप। यहीं हमारे सामने से शुरू होकर और हमारे देखते ही देखते हमारी दृष्टि सीमा से ऊंचे, कहीं अबूझ और अपार होती व्यवस्था के प्रति हमारी प्रतिक्रिया भी इन कविताओं में है, और विषाद भी। हमारे जीने का उछाह भी इनमें है और अवसाद भी। इनमें हमारा बड़ा होना भी है और छोटा होना भी, हमारी हिंसा भी और हमारी करुणा भी।''[1]

पवन करण अपनी कविताओं की भाषा में जितने सहज, सरल एवं संवेदी हैं उनकी कविताओं के विषय चयन में वे उतने ही अलग हैं और बाकी कवियों से विशिष्ट भी। वे अपनी कविता के विषय चयन को लेकर सारी वर्जना के

विपरीत किसी पुरानी परम्परा का अन्धानुकरण न करते हुए अपने नए मानक, नए विषय, जीवन के प्रत्येक क्षण का यथार्थ बहुत ही सहजता से व्यक्त कर देते हैं। यही कारण है कि हिंदी कविता में शायद पहली बार 'प्यार में डूबी हुई माँ' ने प्रवेश पाया है। 'स्त्री मेरे भीतर' कविता संग्रह की भूमिका में विष्णु नागर कहते हैं—"एक औरत जो अपनी युवावस्था में अचानक विधवा हो गयी हो, जिसने वर्षों उस अकेलेपन और निराशा में गुजारे हों, जिसमें दुनिया की हर खुशी में सिर्फ अपने व्यक्तिगत दु:ख की छाया ही नजर आती है, उसके जीवन में अचानक चुपके से कोई पुरुष आए (वह पुरुष विवाहित है या अविवाहित, यह मायने नहीं रखता और बहुत उचित ही पवन ने इस बारे में कविता में मौन बरता है।) और उसके इस तरह आने का सिर्फ मौन स्वागत ही उसकी बेटी न करे, इस कारण अपने को केवल दुनिया की सबसे खुशनसीब लड़की ही न समझे, बल्कि इस वजह से बौराई-पगलाई-सी रहे और उसे अपनी प्रेम करती हुई माँ उसके स्कूल की ही कोई शरारती, चंचल और हंसमुख लड़की लगने लगे, इस तरह की बात इससे पहले कहने और समझने का साहस किसी कवि ने नहीं किया।"[2]

जिस सहज भाषा में एक पुत्री अपने मृत पिता की फ्रेम से बात करते हुए अपनी माँ के प्रेम को व्यक्त करती है वह पवन करण की कविता के कथ्य की एक महत्त्वपूर्ण उपलब्धि है। जिस गहन संवेदना को सहज शब्दों में एक पुत्री के माध्यम से प्रस्तुत करना बिना किसी अश्लीलता के विषय को एक महत्त्वपूर्ण स्थान देती है—

अब तुम्हें वाकई नहीं मालूम पिता कि माँ
इस उम्र में कितनी खूबसूरत देती है दिखाई
और प्रेम करती हुई माँ को देखती
मैं क्यों न फिरूँ बौराई
प्रेम करती हुई माँ इन दिनों
बिल्कुल मुझ जैसी लगने लगी है
जैसे मेरी स्कूल की कोई सहेली
शरारती चंचल और हंसमुख[3]

पवन करण की कविताओं ने स्त्री मन को एक मुखर अभिव्यक्ति दी है। उनकी कविताओं में झांकता स्त्री मन अपनी हर घुटन, हर चीत्कार, अपना हर दर्द, हर संवेदना को बड़े ही संयत और सहज रूप में प्रस्तुत करता है। यह सहजता ही उन पात्रों से आत्मीयता जुड़ाती है, पाठक को उन अहसासों का साझी बनाती है।

पवन करण की कविताओं में आई नारी पात्र केवल अपनी व्यथा कथा ही नहीं बताती, केवल संवेदना का विषय ही नहीं बन कर आती, वह अपने सम्पूर्ण अस्तित्व के साथ कविताओं का केन्द्र बिन्दु बनकर उभरती हैं। उनकी कविताओं में नारी-मन की अनेक परते हैं जहाँ वह पारिवारिक -सामाजिक अंकुशों के भीतर भी अपनी परवाज तोल रही है। अपने आत्मविश्वास को परख रही है। अपना विरोध, अपना विद्रोह व्यक्त कर रही है किन्तु बहुत ही संयम और धैर्य के साथ। बड़ी सहजता से परम्पराओं को करवट देते हुए परिवर्तित कर रही है। वह स्त्री विमर्श का बिगुल बजाते हुए क्रान्ति की अलख नहीं जगाती किन्तु अपने आप को बदलते हुए, यथार्थ को स्वीकार करते हुए अपने जीवन मूल्यों के साथ आगे बढ़ रही है। हाँ, स्त्री शतक के दो खंडों में उन्होंने पौराणिक स्त्री पात्रों के माध्यम से प्रश्न तो उपस्थित किए हैं इस पुरुष वर्चस्ववादी समाज के समक्ष। मैं अपने आलेख के माध्यम से पवन करण की कविताओं में व्याप्त इसी नारी मन की अभिव्यक्ति को स्पष्ट करने का प्रयास करूँगी।

पवन करण की कविताओं में स्त्री-पुरुष संबंधों के अनेक भाव चित्र बिखरे हुए हैं। ये सभी विषय हमारे आसपास के जीवन में बिखरे हुए मिल जाएँगे इसी कारण हम इन्हें पढ़कर असहज नहीं होते बल्कि इन विषयों को कविता के विषय के रूप में देख कर आगे बढ़ने से पहले कुछ रुक कर गम्भीर होकर चिन्तन अवश्य करते हैं। पवन करण के काव्य-संग्रह 'कोट के बाजू पर बटन' के फ्लैप पर उल्लिखित उद्धरण से शायद बहुत अधिक स्पष्ट हो पाए—"भले ही टेकनोलॉजी और मैनेजमेंट के प्रशिक्षण ने बहुत जगहों पर आदमी को ही हाशिए पर सरका दिया हो किन्तु मध्यवर्गीय भद्रलोक की वर्जनाओं से भिड़न्त की धमक वाली ये कविताएँ पाठक के संवेदनतन्त्र में कुछ अलग ही प्रकार से हलचल पैदा करती हैं, क्योंकि भारतीय समाज अभी अपना नग्न फोटोसेशन कराने को उत्सुक प्रेमिका तथा बेटी और प्रेमिका के बीच पिता के प्यार के अन्तर तथा विवाह की तैयारी करती प्रेमिका से पति की आन्तरिकता को जानने को उत्सुक आहत प्रेमी को अपने संस्कारों के बीच जगह नहीं दे पाया है।"[4]

अपनी कई कविताओं में पवन करण ने पुरुष मन के माध्यम से स्त्री को समझाया है। पुरुष की सोच में स्त्री के मनोभावों की अभिव्यक्ति बड़े ही निश्चल रूप से की है। 'अपने विवाह की तैयारी करती प्रेमिका' कविता में प्रेमिका अन्तर्द्वंद तो स्पष्ट ही दीखता है जो अपने ऑफिस में कार्यरत अपने प्रेमी से अपने ही विवाह की तैयारी करते रहने के बीच भी अपने प्रेम को अभिव्यक्त करती है

साथ ही होने वाले पति के प्रति उसमें तनिक भी अनुरक्तता नहीं दीखती। प्रेमी न तो उसे अपना सकता है और उसे किसी और का होते देखने का दुःख भी कविता में पुरजोर दिखाई देता है। प्रेमिका की अभिव्यक्ति का खुलापन भी परिवर्तन की सौंधी-सी खुशबू का झोंका सा लगता है—

मगर मैं उसके साथ एक दिन भी नहीं रहने वाली
तुम्हारे और अपने घर के कहने पर मैं यह शादी कर रही हूँ
तुम जानते हो न तुम्हारे बिना नहीं रह सकती मैं
छोड़ कर चली आऊँगी सब, सुन रहे हो न
मैं हताश उसकी बेचैनी पर हाँ मैं हिला देता हूँ अपना सिर[6]

'फोटोसेशन' कविता में अवश्य स्त्री की बहुत ही नितान्त वैयक्तिक अभिव्यक्ति, खुलापन, स्त्री स्वातन्त्र्य का एक अलग पक्ष उभरता है, किन्तु इस कविता में स्त्री विमर्श के कई नए आयाम भी दृष्टिगत होते हैं—

जिसे तुम बार-बार मुझ पर लुटा देने की कहते हो
मुझे तुम्हारी वह जान नहीं चाहिए
नहीं चाहिए मुझे तुम्हारी वह ओट
जिसके पीछे मैं खुद को सुरक्षित मानतीआई हूँ
मैं उस ओट से बाहर आकर/तुम्हारे आगे खड़ी होना चाहती हूँ[6]

स्त्री के जीवन का यह एक क्रान्तिकारी पक्ष है जहाँ वह अपनी देह को बन्धन नहीं मानती और ना ही सात जन्मों के रिश्तों पर विश्वास करती है वह इस एक जीवन को ही खुलकर, भरपूर जीना चाहती है अपनी सभी इच्छाओं और कामनाओं की पूर्ति के साथ—

मुझ पर बहुत भार है अपनी इस देह का
मैं खुद को हल्का महसूस करना चाहती हूँ,
तुम्हारे साथ सपनों और चाहतों से लबालब सात नहीं
बस एक जीवन जीना चाहती हूँ
और उसी चाहत भरे जीवन से निकलकर बाहर आई
यह मेरी एक इच्छा है जिसे मैं पूरा करना चाहती हूँ
मैं तुम्हें ये भी बता देना चाहती हूँ ये कोई
ऐसी पहली और अन्तिम इच्छा नहीं मेरी
इसके बाद भी मैं इच्छाओं और कामनाओं से
लबालब एक लड़की ही रहूँगी
मैं इस इच्छा के पूरी होते ही कोई कैवल्य नहीं पा लूँगी[7]

साथ ही होने वाले पति के प्रति उसमें तनिक भी अनुरक्तता नहीं दीखती। प्रेमी न तो उसे अपना सकता है और उसे किसी और का होते देखने का दुःख भी कविता में पुरजोर दिखाई देता है। प्रेमिका की अभिव्यक्ति का खुलापन भी परिवर्तन की सौंधी-सी खुशबू का झोंका सा लगता है—

मगर मैं उसके साथ एक दिन भी नहीं रहने वाली
तुम्हारे और अपने घर के कहने पर मैं यह शादी कर रही हूँ
तुम जानते हो न तुम्हारे बिना नहीं रह सकती मैं
छोड़ कर चली आऊँगी सब, सुन रहे हो न
मैं हताश उसकी बेचैनी पर हाँ मैं हिला देता हूँ अपना सिर[6]

'फोटोसेशन' कविता में अवश्य स्त्री की बहुत ही नितान्त वैयक्तिक अभिव्यक्ति, खुलापन, स्त्री स्वातन्त्र्य का एक अलग पक्ष उभरता है, किन्तु इस कविता में स्त्री विमर्श के कई नए आयाम भी दृष्टिगत होते हैं—

जिसे तुम बार-बार मुझ पर लुटा देने की कहते हो
मुझे तुम्हारी वह जान नहीं चाहिए
नहीं चाहिए मुझे तुम्हारी वह ओट
जिसके पीछे मैं खुद को सुरक्षित मानतीआई हूँ

इसके बाद भी मैं इच्छाओं और कामनाओं से
लबालब एक लड़की ही रहूँगी
मैं इस इच्छा के पूरी होते ही कोई कैवल्य नहीं पा लूँगी[7]

बिना किसी लाग लपेट, बिना किसी आवरण के नारी मुक्ति का सहज जयघोष पवन करण की कविताओं को महत्त्वपूर्ण बना देता है। 'दरअसल उसको समझना खुद को समझना है' कविता में कवि ने पुरुषों के माध्यम से स्त्री चरित्र को समझा है। एक पुरुष अपनी पत्नी के उसके प्रेमी के साथ रंगे हाथों पकड़े जाने के बाद की स्थिति पर अपने मित्र के साथ विचार कर रहा है। कवि मित्र के माध्यम से पुरुष मन को आईना दिखाता है कि जब तुम किसी और की पत्नी के साथ प्रेम में रत रहते हो तब उस स्त्री के पति और हम प्रेमी क्या अलग-अलग पुरुष हैं?—

दरअसल उसे समझना खुद को समझना है
इस बात का कोई अर्थ नहीं कि तुम्हीं-
इसके शिकार क्यों हुए मैं तुम्हीं से पूछता हूँ
तुम्हें ही इस सब का शिकार क्यों नहीं होना चाहिए था[8]

पवन करण ने अपनी कविताओं में नारी मन को कभी नारी की नजर से देखा है तो कहीं पुरुष चरित्रों की नजर से भी स्त्री संबंधों के कई कई रूप उकेरे हैं। ऐसी ही एक कविता है—'एक खूबसूरत बेटी का पिता' जहाँ पिता अपनी बेटी की सुन्दरता पर चिंतित है। यह कविता बड़े ही सुन्दर एवं भावुक शब्दों में एक पिता की अभिव्यक्ति है। अपनी युवा बेटी के भविष्य, उसके सपनों, उसके प्रेम को सहारा देता एक पिता अन्त में आश्वासन देता अपनी पुत्री को—

सिर्फ भय ही नहीं एक खूबसूरत बेटी का पिता होने का
जो उल्लास होना चाहिए मेरे भीतर
वह मेरे भीतर है और दो गुना है
फिर भी मेरी चिन्ता में मेरी बेटी की खूबसूरती
शामिल है और शामिल है यह दृढ़ता
यदि इस सब के बावजूद भी
उससे कोई गलती होती है तो हो जाए
उसके पीछे उसे उबारने के लिए मैं खड़ा हूँ तत्पर[9]

पिता-पुत्री के संबंधों की कई कविताएँ पवन करण ने लिखी है। 'वह अब मुझसे भी डरने लगी है' कविता में पिता का अपनी बेटी की उम्र की लड़की से प्रेम करना तथा अपनी बेटी की नजरों में अपने पिता के प्रति भय को पवन करण ने एक अलग ही भूमि पर रचा है। जहाँ पिता अपनी बेटी की आँखों में अपने लिए भय को पाता है—

मैं अब उसके लिए पिता नहीं रहा
मुझमें अब उसे एक पुरुष नजर आने लगा है
उसे मेरे चेहरे में अब उस औरत का चेहरा
दिखाई देने लगा है जिसे लेकर इन दिनों
उसकी माँ की साँस गले में अटकी है
जिसके प्रेम मे में इन दिनों बेतहाशा डूबा हूँ[10]

पिता को यह खीझ है कि उसकी बेटी अब उससे नजरें चुराती है। उसके मन में यह संकोच है कि शायद इन दिनों में उसे उन आवारा, मनचले लड़कों जैसा लगता हूँ जो उसे रास्ते चलते छेड़ते हैं। पिता को लगता है कि मैंने अपने प्रेम को पाकर, बेटी की नजरों में अपना पिता होना खो दिया है। पिता के लिए अपनी बेटी की उम्र की प्रेमिका द्वारा बेटी से खुद की तुलना करना भी संकुचित करता है—

और उस वक्त तो खुद को लेकर
बेटी के भीतर पैदा हुआ भय
मुझे सच लगने लगता है
जब वह जिसके प्रेम में इन दिनों
खोया हूँ मैं अगाध, अपनी तुलना
मेरी युवा बेटी से करते हुए
मुझसे पूछती है, बताओ दोनों में से
तुम किसे ज्यादा प्यार करते हो
अपनी बेटी को या मुझे[11]

इस कविता में पिता अपनी पुत्री के मनोभावों को समझ रहा है। उसकी संवेदना से जुड़ा है पुत्री के प्रति उसका मन। यहाँ पिता बेटी के मन को पढ़ने का प्रयास कर रहा है। इसी प्रकार की एक और कविता है—'पिता की आँख में पराई औरत'। इस कविता में बेटी अपने पिता के मन को पढ़ रही है स्थिति कमोबेश वही है बस नजरिया थोड़ा सा बदला है। इसमें पुत्री अपने पिता के प्रेम के प्रति कहीं न कहीं संवेदनशील भी है। वह अपनी माँ और पिता के संबंधों की कई प्रकार से व्याख्या करती है। वह पिता से झगड़ा भी करना चाहती हैं पर पिता के प्रेम को समझने का प्रयास भी करती है—

एक बार तो उसके मन में आया वह अपने सामने बिठाकर
पिता को डांट दे बुरी तरह, ज्यादा हो तो झापड़ जड़ दे दो-चार
उनसे कहे क्या हो रहा है ये सब

पापा यह सब आपको अच्छा नहीं लगता अब
देखो मैं भी अब बड़ी हो गयी हूँ।
यह सब करने की तो अब मेरी उम्र है
मगर जब अपने भीतर किसी नवयुवक-सी बेचैनी लिए
सज-धजकर घर से बाहर
भागते पिता को देख तो खुद को समझाती है
नहीं यार मेरे बड़े हो जाने का मतलब
यह नहीं कि चुक गये हैं पिता शायद
उनका जीवन शुरू हुआ यहीं से[12]

पिता-पुत्री संबंधों के कई-कई आयाम पवन करण की कविताओं में स्वतन्त्र एवं निर्बाध रूप से अभिव्यक्त हुए हैं। अभिव्यक्ति की स्वतन्त्रता का एक और पक्ष है जहाँ पुत्री अपने मृत पिता को अपनी माँ के प्रेम के बारे में बताती है। इस कविता में कवि ने पुत्री के माध्यम से स्त्री के प्रति जो उदार संवेदनशीलता दिखाई है वह समकालीन हिंदी कविता की एक महत्त्वपूर्ण उपलब्धि है। इस कविता में उस पुत्री की खुशी में संवेदना की वह उजास है जो उसकी माँ के जीवन में कई वर्षों के बाद आई है। वह पुत्री साक्षी है अपनी माँ के उन दु:खों भरे वर्षों की जो उसने वैधव्य के कारण बिताए हैं वह माँ के अपने मृत पति के प्रेम को भी जानती है तभी वह खुश है। विष्णु नागर के शब्दों में—''पूरी कविता में कवि कहीं हस्तक्षेप करता नहीं दीखता, अन्धेरे में दिया लेकर चलने का अभिनय करता नहीं दीखता, वह अपनी कविता को पूरी तरह प्यार में डूबी हुई माँ की बेटी के हवाले कर देता है और उसे ही बोलने देता है। यह कविता उस लड़की की कविता है या कहें गीत है, उसकी गुनगुनाहट है, उसके बौराएपन का संगीत है।''[13]

स्त्री-पुरुष संबंधों के अतिरिक्त स्त्री से जब सामाजिक संबंध टकराए, जहाँ परिवार और स्त्री के विचार आमने- सामने आए उन कविताओं में स्त्री मन अपनी तमाम वर्जनाओं के बावजूद उभर कर आया। पवन करण की कविताओं में स्त्री अपने हक के लिए आवाज उठाना शुरू कर देती है। 'हक' कविता में स्त्री का अपने परिवार से संघर्ष मुखर है—

मैंने अपनी पसन्द के पुरुष को प्रेम- पत्र लिखा
तुमने मेरी पढ़ाई बन्द करवा दी
मैं अपनी चाहत के पुरुष से छुपकर मिली
तुमने घर के दरवाजों में कैद कर दिया मुझे

मैंने अपनी इच्छा के पुरुष से
प्रेम-विवाह करने को कहा, तुमने कोशिश की
मेरी जुबान पर ताला डालने की
मैंने तुम्हारी इच्छा के खिलाफ जाकर अपना ब्याह रचाया
तुमने मेरे साथ-साथ उसे भी मार डाला
या फिर मुझे मरा मान लिया हमेशा के लिए[14]

स्त्री का विरोध यहीं समाप्त नहीं होता। वह प्रश्न करती है, अपने परिवार से अपना हक माँगती है—

तुम भले ही मुझे मरा मान लो
और कभी मेरा चेहरा ना देखो
मगर उससे पहले मेरे हिस्से का पैसा तो मुझे दो
मेरे पूछने पर तुम ही तो कहते थे
हम अपने हक के लिए लड़ते आए हैं
प्रेम पर मेरा हक था तो पैसे पर भी तो मेरा हक है
क्या मुझे अब इसके लिए भी लड़ना पड़ेगा[15]

यह अपने अधिकार के प्रति सचेत स्त्री का स्वर है जो अपेक्षाकृत अधिक मुखर है। सभी स्त्रियाँ इतनी मुखर नहीं हो पाती। कुछ स्त्रियाँ विद्रोह नहीं करती, बस अचानक अपनी उड़ान से अपनी सोच समाज को सौंपती है। 'उड़ान' कविता में स्त्री की उसी सोच को कवि ने वाणी दी है। घर-परिवार स्त्री पर पाबन्दी लगाता है, वह नहीं जान पाता कि स्त्री अपने सपनों की उड़ान को, अपने परों को सबसे छुपा कर खुले आकाश में उड़ना सीख रही है। एक दिन वह अपने पूरे आत्मविश्वास के साथ सपनों के आकाश में उड़ जाती है। कवि सन्देश देता है—

जो घर स्त्री की उड़ान को
नहीं पहचानते
उनसे उड़कर जाने वाली स्त्रियाँ
कभी वापस नहीं लौटती
आकाश छूकर
बस उनकी उड़ान लौटती है[16]

ये सभी स्त्रियाँ समकालीन काव्य जगत की आधुनिक स्त्रियाँ हैं जो समाज के बीच अपनी स्थिति को स्वयं स्थापित करती हैं। पवन करण ने इसके अतिरिक्त इतिहास के पन्नों से उपेक्षित, विस्मृत करा दी गयी उन पौराणिक स्त्री पात्रों को

अपनी कविता में स्थान दिया है। पवन करण का प्रसिद्ध काव्य-संग्रह है—स्त्री' शतक'। यह दो खंडों में प्रकाशित है इसके प्रत्येक खंड में सौ कविताएँ हैं। ये सभी कविताएँ उन मिथकीय स्त्री पात्रों के प्रश्न हैं इस पुरुष वर्चस्ववादी समाज से कि क्यों उन्हें इस तरह बिसरा दिया गया? पवन करण का 'स्त्री-शतक' उनके काव्य जीवन की सबसे महत्त्वपूर्ण उपलब्धि है। यह काव्य-संग्रह स्त्री की वेदना, उसकी करुणा, उसकी निराशा या द्वन्द्व की ही अभिव्यक्ति नहीं है यह उसकी चैतन्य शक्ति, उसके साहस, उसके जीवन का जीवन्त आख्यान है। 'स्त्री-शतक' पुरुषवादी सत्ता के अहंकार पर एक प्रहार है।

'स्त्री-शतक' में कई-कई नारी पात्रों की कथा है जो अपने आँचल में कई-कई विमर्श छुपाए हुए हैं। पौराणिक आख्यान के अनुसार 'तारा' कविता में तारा बृहस्पति की पत्नी थी, जिसे बृहस्पति का शिष्य चन्द्रमा भगाकर ले जाता है और उन दोनों के अनैतिक संबंध से बुध का जन्म होता है—

यदि तुम्हें कभी तारा मिले तो उससे पूछना
तो वह बताएगी चमक का घर
गहरे अन्धेरे में डूबा रहता है
किसी पुरुष का किसी स्त्री के चेहरे में चन्द्र देख लेना चन्द्र को
खुद उसके चेहरे का पता बता देना है[17]

इसी सन्दर्भ में 'ममता' कविता में एक और स्त्री चरित्र उभरता है जो देव गुरु बृहस्पति के एक अन्य रूप से हमारी पहचान कराता है। ममता बृहस्पति के भाई उतथ्य की पत्नी जिसके साथ गर्भावस्था के दौरान बृहस्पति ने सम्भोग किया। वह बृहस्पति से प्रश्न करती है—

तुम कौन सा मुँह लेकर चन्द्र से
तारा को वापस माँगने जा रहे हो
भाई की पत्नी होते हुए भी तुमने
जिस तरह, अपमानित किया मुझे
चन्द्र ने तो वैसा नहीं किया तुम्हारे साथ[18]

इन सभी प्रश्नों के सामने हमारा इतिहास मौन है किन्तु पवन करण की कविताओं में ये सभी स्त्रियाँ दिल खोलकर अपनी व्यथा कथा कहती है। इन दुखिनी नारियों में केवल ऋषिकुल की नारियाँ ही नहीं, राजा-महाराजाओं की रानियाँ-दासियाँ, देव पत्नी तथा देव पुत्रियाँ, साथ ही पुरुषोत्तम कहलाने वाले देवताओं की बहनें भी हैं। मर्यादा पुरुषोत्तम दशरथ नन्दन राम की बहन शान्ता भी

दुःखी है। सरमा (रावण की दासी), सीता से शान्ता के बारे में प्रश्न करती है—

जब दशरथ उसे ऋषयश्रंग
को सौंप रहे थे तब क्या उसने
तुमसे कहा कि मैं किसी
ऋषि से नहीं राम भैया जैसे किसी
राजकुमार से ब्याह करना चाहती हूँ
भाभी तुम इन आर्यों को समझाओ न
कि वे मुझे यज्ञदान में नहीं सौंपे
मेरी पसन्द भी पूछे मुझसे, चलने दें
मेरी भी ब्याह की बात किसी योद्धा से[19]

एक और भी बहन है—एकानंगा (एकाँगा) जो गोकुल में कृष्ण की बहन है—

जैसे नाम सुनकर सब शान्ता का
जताते आश्चर्य/कि राम की बहन भी थी एक
अरे हमने तो सुना ही नहीं कभी
बारे में उस लुप्त भगिनी के
खुद की अनदेखी वे बहनें थीं हम
जो अपने-अपने कालखंड की
स्मृतियों में छूटती गयी सबसे पीछे
जबकि हम में से एक
कृष्ण की बहन थी और एक राम की[20]

देवराज इन्द्र, राजा बलि से धरती हथियाने के लिए अपनी पुत्री जयन्ति को वृद्ध शुक्र को दे देते हैं। तब कवि जयन्ति से प्रश्न करता है—

जयन्ति बूढ़े शुक्र की अंकशायिनी होने से पहले
तुमने खुद के बारे में नहीं सोचा
तुम्हें पिता की बात मानने से पहले
माँ शचि एक बार भी याद नहीं आई
नहुष से खुद को बचाने में सफल शचि
तुम्हें पितृ-आज्ञा न मानने का सुझाव देती
तुम्हें बताती कि तुम्हारे पिता को स्त्री-शीलता
दाँव पर लगाने में हिचक नहीं होती

नंदिनी और उर्वशी में अन्तर नहीं उसके लिए[21]

स्त्री शतक की स्त्रियाँ अपने अस्तित्व के प्रति अधिक जागरूक व सचेत मालूम पड़ती है। ऋषि दधीचि जिन्होंने अपनी हड्डियों का दान इन्द्र को दिया था वज्र निर्माण हेतु, उनकी पत्नी सुवर्चा का प्रश्न कितना सटीक है। 'सुवर्चा' कविता में वह अपने पति से प्रश्न करती है—

वज्र निर्माण के लिए अपनी हड्डियाँ
इन्द्र को सौंपते समय तुमने
मुझसे एक बार भी नहीं पूछा ऋषिवर
क्या बस मैं ही तुम्हारी अर्धांगिनी थी
तुम अर्धांग नहीं थे मेरे
क्या मेरी ही देह पर तुम्हारा
अधिकार था, तुम्हारी देह पर
कोई अधिकार नहीं था मेरा
फिर तुमने मेरी सहमति लिए बिना
अपना देह-आधार
कैसे दे दिया किसी को
तुम्हारी आज्ञा के बिना क्या मैं
कभी किसी को स्वयं का
कुछ सौंप सकती थी[22]

इसी प्रकार इस काव्य-संग्रह में कई मुखर नारी पात्र हैं—धृतराष्ट्र की दासी नयना, बाल विधवा उलूपी, घटोत्कच की पत्नी मोर्वी, विदुर की माँ इन्दु, राजा पृथु की पत्नी अर्ची, राजा शर्याति की पुत्री सुकन्या, शर्मिष्ठा, दुर्योधन की पत्नी भानुमति, भीम की पत्नी हिडिम्बा, कृष्ण की आठों पत्नियाँ, रायाणी आदि की अन्य-अन्य कथाएँ हैं। 'स्त्री-शतक' की भूमिका में राधावल्लभ त्रिपाठी जी लिखते हैं—"पवन करण ने इस शतक में आख्यानों को खंगालते हुए, मिथकों में गोता लगाते हुए ऐसे स्त्री पात्र हमारे सामने खड़े कर दिए हैं जिनकी अथाह व्यथा कथा प्राय: उपेक्षित अनजानी रह गयी है।"[23]

अत: निष्कर्ष रूप से कहा जा सकता है कि पवन करण की कविताएँ स्त्री मन का वह आइना है जहाँ से व्यक्ति स्त्री-जीवन को उसकी पूर्ण संवेदना के साथ

देख-सुन महसूस कर सकता है। आपकी कविताएँ स्त्री जीवन के विविध सन्दर्भों को नए-नए विषयों से रूबरू कराती हैं।

राधा की अंतरंग अनुभूतियों का गायन : कनुप्रिया

—डॉ. नीता त्रिवेदी

आधुनिककाल में कृष्ण साहित्य की दो महत्त्वपूर्ण कृतियाँ हैं—'अंधा युग' और 'कनुप्रिया'। इन दोनों कृतियों के रचनाकार एक ही है सर्वतो मुखी प्रतिभा संपन्न प्रख्यात कवि एवं कथाकार डॉ. धर्मवीर भारती। आपने साहित्य की कई विधाओं यथा कविता, कहानी, उपन्यास, नाटक, निबंध, आलोचना, अनुवाद, रिपोर्ताज आदि में अपनी लेखनी से विशिष्ट छाप छोड़ी है।

'अंधा युग' तथा 'कनुप्रिया' दोनों ही युद्ध और शांति के चरम क्षणों का काव्य है। दोनों में ही महाभारत के युद्ध और उसके बाद की अशांति, थकन, विवशता आदि पर लेखक के विचार हैं किंतु दोनों ही काव्य दो अलग-अलग ध्रुवों पर खड़े होकर युद्ध की विभीषिका को देख रहे हैं। कनुप्रिया में प्रेम की तन्मयता अपने चरम पर है। धर्मवीर भारती 'कनुप्रिया' की भूमिका में लिखते हैं दृश्लेखक के पिछले दृश्य काव्य में एक बिंदु से इस समस्या पर दृष्टिपात किया जा चुका है। गांधारी, युयुत्सु और अश्वत्थामा के माध्यम से। कनुप्रिया उनसे सर्वथा पृथक् बिल्कुल दूसरे बिंदु से चलकर उसी समस्या तक पहुँचती है, उसी प्रक्रिया को दूसरे भाव स्तर से देखती है और अपने अनजान में ही प्रश्न के ऐसे संदर्भ उद्घाटित करती है जो पूरक सिद्ध होते हैं। पर यह सब उसके अनजान में होता है क्योंकि उसकी मूल वृत्ति संशय या जिज्ञासा नहीं, भावाकुल तन्मयता है। कनुप्रिया की सारी प्रतिक्रियाएँ उसी तन्मयता की विभिन्न स्थितियाँ हैं।[1]

कनुप्रिया अर्थात कृष्ण की प्रिया, उनकी आराधिका-राधा। यह संपूर्ण काव्य राधा कृष्ण के प्रणयप्रसंग, कृष्ण के विरह में राधा की स्थिति, राधा की दृष्टि से कृष्ण, उनके प्रेम का अवलोकन करता है। उपमा ऋचा ने अपने एक लेख में

लिखा है—''कृष्ण को शरण देने वाला ये हृदय उसी आराधिका का है, जो पहले राधिका बनी और फिर राधिका से कृष्ण की आराध्या हो गई। कृष्ण आराधना करते हैं, इसलिए ये राधा है या ये कृष्ण की आराधना करती है, इसलिए राधिका कहलाती है। सच, बहुत कठिन है इसको परिभाषित करना क्योंकि इसकी परिभाषा स्वयं कृष्ण है खुद को असाधारण होने की सीमा तक साधारण बनाए रखने वाली ये किशोरी कृष्ण को अनायास ही मिली थी भागवत में। भागवत, रस का गीत है। उस गीत का रस भी और कोई नहीं, यही आराधिका है।''[12] पुरुष और प्रकृति के विविध प्रतीकों के माध्यम से सृष्टि के रहस्योद्घाटन के साथ ही प्रेम की तन्मयता और राधा की सहजता, विराटता और मन के कई सहज सुलभ प्रश्न हैं कनुप्रिया में जिनके प्रति उत्तर न तो इतिहास के पास है न ही वर्तमान के पास।

डॉ. धर्मवीर भारती 'कनुप्रिया' की भूमिका में इसे स्पष्ट करते हैं—''ऐसे तो क्षण होते ही हैं जब लगता है कि इतिहास की दुर्दांत शक्तियाँ अपनी निर्मम गति से बढ़ रही हैं, जिनमें कभी हम अपने को विवश पाते हैं, कभी विक्षुब्ध, कभी विद्रोही और प्रतिशोध युक्त, कभी वल्गाएँ हाथ में लेकर गतिनायक या व्याख्याकार, तो कभी चुपचाप शाप या सलीब स्वीकार करते हुए आत्मबलिदानी उद्धारक यात्राता[3], लेकिन ऐसे भी क्षण होते हैं जब हमें लगता है कि यह सब जो बाहर का उद्वेग है। महत्त्व उसका नहीं है। महत्त्व उसका है जो हमारे अंदर साक्षात्कृत होता है—चरम तन्मयता का क्षण जो एक स्तर पर सारे बाह्य इतिहास की प्रक्रिया से ज्यादा मूल्यवान सिद्ध होता है, जो क्षण हमें सीपी की तरह खोल गया है। इस तरह कि समस्त बाह्य,अतीत, वर्तमान और भविष्य, सिमटकर उस क्षण में पुंजीभूत हो गया है, और हम हम नहीं रहे।''[13]

'अंधायुग' में बाहर का उद्वेग अधिक है। 'कनुप्रिया' तो केवल चरम तन्मयता के उसी क्षण का काव्य है जिसके आलोक में बाह्य जगत भी उसी क्षण में समाहित हो जाता है। वैसे तो संपूर्ण काव्य ही राधा का आत्मकथन है किंतु जिस सहजता, जिस प्रेम की कसौटी पर राधा इस बाह्य जगत को, अपनी सृष्टि के केंद्र कान्हा को समझती है, परखती है वहीं राधा की तन्मयता संपूर्ण काव्य, समस्त चराचर से बड़ी हो जाती है इसी संदर्भ में भारती जी 'कनुप्रिया' की भूमिका में आगे लिखते हैं—''लेकिन वह क्या करें जिसने अपने मन से जीवन जिया है, तन्मयता के क्षणों में डूब कर सार्थकता पाई है, और जो अब उद्घोषित महानताओं से अभिभूत और आतंकित नहीं होता बल्कि आग्रह करता है कि वह उस सहज की कसौटी पर समस्त को कसेगा। ऐसा ही आग्रह है कनुप्रिया का।''[14]

'कनुप्रिया' राधा के मन की अंतरंग अनुभूतियों का गायन है, राधा का, उसके प्रेम का, सहज प्रस्फुटन है। प्रेम की सहजता से परिपक्वता की स्थिति तक की यात्रा है कनुप्रिया। भारती जी ने संपूर्ण काव्य को पाँच खंडों में विभक्त किया है—पूर्वराग-मंजरी, परिणय, सृष्टि-संकल्प, इतिहास तथा समापन, पूर्वराग-मंजरी, परिणय और सृष्टि-संकल्प के अंतर्गत राधा कृष्ण के बहुमुखी प्रणय के विविध आयामों से प्रेम की निर्मल अजस्र धारा प्रवाहित हो रही है जो इतिहास तथा समापन में कई मोड़ो से गुजरती हुई राधा और कृष्ण को एक नए रूप में व्याख्यायित करती है। एक नई दृष्टि प्रदान करती है। डॉ. परविंदर कौर के अनुसार—"कनुप्रिया राधा-कृष्ण के प्रेम का मनोवैज्ञानिक विकास है। पूर्वराग मंजरी, परिणय, सृष्टि-संकल्प, इतिहास और समापन के अंतर्गत राधा की प्रेमाभिव्यक्ति में कहीं भी अस्वाभाविकता का आभास नहीं होता, अपितु मनोवैज्ञानिक भाव-बोध है।"[5]

कृष्ण, महाभारत युद्ध के बाद नितांत एकाकी, थके हुए, व्याकुल, संशयग्रस्त होकर अपनी राधा को पुकारते हैं और राधा इसी क्षण की प्रतीक्षा में उसी अशोक वृक्ष के नीचे कृष्ण की प्रतीक्षा करती है कि कब उसके कृष्ण उन्हें पुकारे और राधा उन्हें अपने आंचल की छाया में विश्राम देकर सुला दे।

भारती जी ने 'कनुप्रिया' का प्रारंभ राधा के कैशोर्य-सुलभ मानवीय भावों से किया है धीरे.धीरे भावों का विकास एवं उनकी परिपक्वता उत्तरोत्तर विकसित होती है। लेखक ने भूमिका में लिखा है। "पूर्वरागा और मंजरी-परिणय उस विकास का प्रथम चरण, सृष्टि-संकल्प द्वितीय चरण तथा महाभारत काल से जीवन के अंत तक शासक, कूटनीतिज्ञ, व्याख्याकार कृष्ण के इतिहास निर्माण को 'कनुप्रिया' की दृष्टि से देखने वाले खंड-इतिहास तथा समापन इस विकास का तृतीय चरण चित्रित करते हैं।"[6]

पूर्वराग के पाँच गीत तथा मंजरी परिणय के तीन गीत राधा के प्रेम के सहज उच्छ्वास हैं जहाँ राधा के प्रेम की तन्मयता तथा किशोरावस्था का सहज एवं सरल मन अपनी समस्त कमनीयता के साथ मुखर है। सृष्टि-संकल्प में राधा कृष्ण का प्रेम एक अलौकिक आह्लाद, प्रकृति एवं पुरुष के विविध प्रतीकों के माध्यम से पल्लवित एवं प्रस्फुटित होता है। इतिहास खंड में इतिहास निर्माता, द्वारकाधीश, कूटनीतिज्ञ, गीतोपदेशक कृष्ण को कनुप्रिया अपने सहज प्रेम की कसौटी पर देखती है, समझती है, व्याख्यायित करती है। समापन राधा और कृष्ण के उसी प्रेम पर होता है जहाँ राधा कृष्ण की प्रतीक्षा में है और कृष्ण महाभारत युद्ध के पश्चात्

नितांत एकाकी, क्लांत और दुखी हैं। कृष्ण अधूरे हैं राधा के बिना और उन्हीं क्षणों में कृष्ण की पुकार पर प्रतीक्षारत राधा आती है कृष्ण से मिलने, उनकी थकान को दूर करने और उनके एकाकीपन को दूर करने।

भारती जी ने 'कनुप्रिया' में श्रीमद्भागवत के योगीश्वर कृष्ण को दृष्टि में रखते हुए वर्तमान संदर्भों को, समस्याओं को भावनात्मक रूप से समझाने का सार्थक प्रयास किया है। इसमें राधा-कृष्ण दोनों ही नवीन संदर्भों एवं नूतन रूप से उपस्थित हुए हैं। 'कनुप्रिया' के प्रारंभिक गीतों में कृष्ण के प्रेम की दिव्यता, अलौकिकता कई कई रूपों में प्रस्फुटित होती है। राधा-कृष्ण की प्रिया है। कनुप्रिया है, वह कृष्ण की आद्या शक्ति है, प्रकृति स्वरूपा है तथा कृष्ण पुरुष रूप में हैं। राधा प्रकृति के कण-कण में जीवन बनकर परिव्याप्त है। पूर्व राग के प्रथम गीत में ही अशोक वृक्ष राधा के चरणों के स्पर्श की प्रतीक्षा में जन्मों से पुष्पहीन खड़ा है—

ओपथ के किनारे खड़े
छायादार पावन अशोक-वृक्ष
तुम यह क्यों कहते हो कि
तुम मेरे चरणों के स्पर्श की प्रतीक्षा में
जन्मों से पुष्पहीन खड़े थे

प्रकृतिस्वरूपा राधा अशोक वृक्ष को समझाती है कि मैं तो कई कई रूपों में तुम्हीं में समाई हूँ—

तुम को क्या मालूम कि
मैं कितनी बार केवल तुम्हारे लिए।
धूल में मिली हूँ
धरती में गहरे उतर
जड़ों के सहारे
तुम्हारे कठोर तने के रेशों में
कलियाँ बन, कोंपलबन, सौरभ बन, लाली बन।
चुपके से सो गई हूँ
कि कब मधुमास आए और तुम कब मेरे
प्रस्फुटन से छा जाओ।[8]

कृष्ण राधा की सांसो में संगीत बनकर समाए हुए हैं। यह राधा के प्रेम की दिव्यता है जहाँ कृष्ण उनसे दूर होकर भी उन्हीं में समाहित है—

यह जो अकस्मात
आज मेरे जिस्म के सितार के
एक-एक तार में तुम झंकार उठे हो—
सच बतलाना मेरे स्वर्णिम संगीत
तुम कब से मुझ में छिपे सो रहे थे।[9]

इन गीतों में राधा कृष्ण के प्रेम की कई कई लीलाएं अभिव्यक्त हुई है। कृष्ण के प्रेम का सम्मोहनए राधा का समर्पण कई कई रूपों में मुखर होता है। एक रूपक दृष्टव्य है—

घाट से लौटते हुए
तीसरे पहर की अलसायी बेला में
मैंने अक्सर तुह्में कदंब के नीचे
चुपचाप ध्यानमग्न खड़े पाया
मैंने कोई अज्ञात वनदेवता समझ
कितनी बार तुह्में प्रणाम कर सिर झुकाया
पर तुम खड़े रहे अडिग, निर्लिप्त, वीतराग, निश्चल!
तुमने कभी उसे स्वीकारा ही नहीं।[10]

पर क्या ऐसा हो सकता है कि राधा का अभिवादन कृष्ण अस्वीकार कर दें। राधा भी मान करते हुए कृष्ण को प्रणाम करना छोड़ देती है पर क्या कृष्ण के सम्मोहन से छूटना इतना भी आसान हो सकता है। राधा के ही शब्दों में—

और क्या मुझे मालूम था कि
तुम केवल निश्चल खड़े नहीं रहे
तुह्में वह प्रणाम की मुद्रा और हाथों की गति
इस तरह भा गयी कि
तुम मेरे एक-एक अंग की एक-एक गति को
पूरी तरह बांध लोगे
इस संपूर्ण के लोभी तुम
भला उस प्रणाम मात्र को क्यों स्वीकारते?
और मुझ पगली को देखो कि मैं
तुह्में समझती थी कि तुम कितने वीतराग हो
कितने निर्लिप्त।[11]

राधा कृष्ण के प्रेम में इतनी बेसुध है कि उसे यमुना के सांवले जल में भी

कृष्ण का आभास होता है। उसे लगता है—

मानो यह यमुना की सांवली गहराई नहीं है
यह तुम हो जो सारे आवरण दूर कर
मुझे चारों ओर से कण-कण, रोम-रोम
अपने श्यामल प्रगाढ़ अथाह आलिंगन में पोर-पोर
कसे हुए हो।[12]

राधा के कृष्ण हर समय, हर पल उसके आसपास ही हैं। उनकी उपस्थिति का आभास राधा को प्रकृति के हर कण-कण में हो रहा है। राधा को रास की पूर्वस्मृति आती है तो उन्हें पश्चाताप भी होता है कि वह रास की रात में कृष्ण के पास से लौट क्यों आयी—

मैं उस दिन लौटी क्यों—
कण-कण अपने को तुम्हें देकर रीत क्यों नहीं गई?
तुमने तो उस रास की रात
जिसे अंशतरू भी आत्मसात किया
उसे संपूर्ण बनाकर
वापस अपने.अपने घर भेज दिया।[13]

पूर्वराग के इन पाँचों गीतों में राधा द्वारा कृष्ण की स्मृति के माध्यम से प्रेम के विविध दृश्य उपस्थित होते हैं। सुलभा बाजीराव ने इन गीतों के संबंध में कहा है—"पूर्वराग के पाँचों गीत स्त्री पुरुष के बीच उत्पन्न होने वाले अनुराग के उत्तरोत्तर अबाध गति से विकसित होने की कथा कहते हैं।"[14]

मंजरी परिणय के अंतर्गत तीन लंबे गीत हैं जिसमें राधा कृष्ण प्रेम के कई-कई बिम्ब, कई रूपक, कई प्रतीक, लौकिक-अलौकिक, कई-कई संकेत अभिव्यक्त होते हैं। राधा कैशोर्य की बाल सुलभ भावना में कई संकेत तो समझ जाती है और कई संकेत जिनके अर्थ उसे कृष्ण के जाने के बाद समझ आते हैं जिस कारण वह दुखी भी है, व्यथित भी। राधा कई-कई रूपों में अपने मनोभाव कृष्ण को समझाती है—

तुम्हारी जन्म-जन्मांतर की रहस्यमयी लीला की
एकांत-संगिनी मैं
इन क्षणों में अकस्मात
तुमसे पृथक नहीं हो जाती मेरे प्राण,
तुम यह क्यों नहीं समझ पाते कि लाज

सिर्फ जिस्म की नहीं होती
मन की भी होती है
एक मधुर भय
एक अनजान संशय
एक आग्रह भरा गोपन,
एक निर्व्याख्या वेदना या उदासी,
जो मुझे बार-बार चरमसुख के क्षणों में भी
अभिभूत कर लेती है।[15]

राधा को दुख है कि कृष्ण के बार-बार बांसुरी बजा कर बुलाने पर भी वह उस शाम आम्र मंजरियों के नीचे नहीं पहुँच पाई। कृष्ण द्वारा उदास मन से पगडंडी पर आम्र मंजरी को चूर-चूर कर बिखेर देने पर राधा कहती है—

यह तुमने क्या किया प्रिय!
क्या अपने अनजाने में ही
उस आम के बौर से मेरी क्वांरी उजली
पवित्र माँग भर रहे थे साँवरे![16]

राधा व्यथित है कि वह कृष्ण के आम के बोर का संकेत नहीं समझ पाई। वह कृष्ण से कहती है—

कतनी बार जब तुमने अर्द्धोन्मीलित कमल भेजा
तो मैं तुरंत समझ गई कि तुमने संझाबिरिया बुलाया है
कितनी बार जब तुमने अंजुरी भर-भर बेले के फूल भेजें
तो मैं समझ गई कि तुह्मारी अंजुरियों ने
किसे याद किया है
कितनी बार जब तुमने अगस्त्य के दो
उजले कटावदार फूल भेजें
तो मैं समझ गई कि
तुम फिर मेरे उजले कटावदार पाँवों में
तीसरे पहर—टीले के पास वाले
सहकार की घनी छांव में
बैठकर महावर लगाना चाहते हो।
आज अगर आम के बोर का संकेत नहीं भी
समझ पायी तो क्या इतना बड़ा मान ठान लोगे ?[17]

राधा कई-कई अर्थों, कई-कई रूपकों से कृष्ण को मनाती है। साथ ही 'तुम मेरे कौन हो?' गीत में कृष्ण के साथ अपने कई-कई संबंध जोड़ती है। हर संबंध में एक नया बिम्ब उभरता है और अंत में इन सभी संबंधों के मध्य से राधा का स्वयं से साक्षात्कार होता है और फिर समस्त सृष्टि, कृष्ण की हर लीला राधा में ही समाहित हो जाती है—

तो मुझे अकस्मात लगा है
कि मेरे अंग-अंग से ज्योति फूटी पड़ रही है
तुह्मारी शक्ति तो मैं ही हूँ
तुह्मारा संबल,
तुह्मारी योगमाया,
इस निखिल पारावार में ही परिव्याप्त हूँ
विराट,
सीमाहीन,
अदम्य,
दुर्दांत[18]

राधा और कृष्ण का प्रेम जब उस विराट स्वरूप को धारण कर लेता है जहाँ उन दोनों के अतिरिक्त समस्त सृष्टि में और किसी का अस्तित्व नहीं है। जहाँ राधा अपने आप से परिचित होती है। वह कहती है।

पर जब मुझे चेत हुआ
तो मैंने पाया कि हाय सीमा कैसी,
मैं तो वह हूँ जिसे दिग्वधू कहते हैं, कालवधू—
समय और दिशाओं की सीमाहीन पगडंडियों पर
अनंत काल से, अनंत दिशाओं में
तुह्मारे साथ-साथ चलती चली आ रही हूँ, चलती
चली जाऊँगी...
इस यात्रा का आदि न तो तुह्में स्मरण है न मुझे
और अंत तो इस यात्रा का है ही नहीं मेरे
सहयात्री![19]

भारती जी ने 'कनुप्रिया के सृष्टि-संकल्प के तीनों गीतों के माध्यम से राधा कृष्ण के प्रेम की विराटता को वाणी दी है। 'सृजन-संगिनी' गीत में सृष्टि के प्रत्येक कण में, उसकी गति-लय में, सृजन-विनाश, प्रवाह सभी में कृष्ण की इच्छा उनकी संकल्प शक्ति का विस्तार है और कृष्ण की संपूर्ण इच्छा का अर्थ

केवल और केवल राधा है—

और यह प्रवाह में बहती हुई
तुह्मारी असंख्य सृष्टियों का क्रम
महज हमारे गहरे प्यार
प्रगाढ़ विलास
और अतृप्त क्रीड़ा की अनंत पुनरावृत्तियाँ हैं—
ओ मेरे स्त्रष्टा
तुह्मारे संपूर्ण अस्तित्व का अर्थ है
मात्र तुह्मारी सृष्टि
तुह्मारी संपूर्ण सृष्टि का अर्थ है
मात्र तुह्मारी इच्छा
और तुह्मारी संपूर्ण इच्छा का अर्थ हूँ
केवल मैं!
केवल मैं!!
केवल मैं!!![20]

समस्त चराचर के प्रत्येक कण में राधा कृष्ण ही है। प्रकृति के संपूर्ण विस्तार में राधा कृष्ण का असीम प्रेम ही परिव्याप्त है। राधा कहती है—

अगर यह निखिल सृष्टि
मेरा ही लीलातन है
तुह्मारे आस्वादन के लिए।[21]

फिर भी राधा के मन में एक आदिम भय व्याप्त है। यह भय प्रकृति स्वरूपा राधा में सहज रूप से उदित होता है। वह अपनी शक्तियों को भी पहचानती है फिर भी एक आदिम भय उसमें है। वह कृष्ण से पूछती है—

और अगर यह चंद्रमा मेरी उंगलियों के
पोरों की छाप है
और मेरे इशारे पर घटता और बढ़ता है
और अगर यह आकाशगंगा मेरे ही
केश-विन्यास की शोभा है
और मेरे एक इंगित पर इसके अनंत
ब्रह्मांड अपनी दिशा बदल सकते हैं—
तो मुझे डर किससे लगता है

मेरे बंधु![22]

'केलिसखी' गीत प्रेम की, अभिसार की अभिव्यक्ति का गीत है। इस गीत में प्रेम की उद्दाम, उत्कंठा, व्याकुलता व्यक्त हुई है—

और भय,
आदिम भय,
तर्कहीन, कारणहीन भय जो
मुझे तुमसे दूर ले गया था, बहुत दूर—
क्या इसीलिए कि मुझे
दुगने आवेग से तुह्मारे पास लौटा लावे
और क्या यह भयकी ही काँपती उंगलियाँ हैं
जो मेरे एक-एक बंधन को शिथिल
करती जा रही हैं
और मैं कुछ कह नहीं पाती![23]

राधा स्वयं को, अपनी शक्तियों को भूल केवल उस क्षण में जीवंत होना चाहती है। प्रकृति अपनी बाह्य शक्तियों को समेट स्वयं में ही समा जाना चाहती है।

यह बाहर फैला-फैला समुद्र मेरा है
पर आज मैं उधर नहीं देखना चाहती
यह प्रगाढ़ अंधेरे के कंठ में झूमती
ग्रहों-उपग्रहों और नक्षत्रों की
ज्योतिर्माला मैं ही हूँ
और असंख्य ब्रह्माण्डों का
दिशाओं का,
समय का
अनंत प्रवाह! मैं ही हूँ
पर आज मैं अपने को भूल जाना चाहती हूँ[24]

इन अंतरंग क्षणों में, समय को बांधकर, दिशाओं को रोककर समस्त ब्रह्मांड में केवल कृष्ण और राधा ये दोनों ही हैं—

आओ मेरे अधैर्य !
दिशाएं घुल गई है
जगत लीन हो चुका है

समय मेरे अलक-पाश में बंध चुका है।
और इस निखिल सृष्टि के
अपार विस्तार में
तुह्मारे साथ मैं हूँ। केवल मैं—
तुह्मारी अंतरंग केलिसखी![25]

राधा कृष्ण की अंतरंग केलिसखी जिनके मिलने से सृष्टि का निर्माण होता है और राधा के थक कर सो जाने पर यह निखिल सृष्टि लय हो जाती है। कृष्ण पुनः अपने संकल्प और इच्छा के द्वारा राधा को जगाते हैं और पुनः सृष्टि का सृजन होता है। इस प्रकार असंख्य सृष्टियों का लय एवं पुनः सृजन राधा कृष्ण के अलौकिक प्रेम के संकल्प एवं इच्छा पर निर्भर है। अतः इस 'सृष्टि-.संकल्प' शीर्षक में राधा कृष्ण का प्रेम केवल लौकिक एवं दैहिक स्तर पर न होकर प्रकृति-पुरुष के दिव्य रूप से ओतप्रोत हो जाता है।

'इतिहास' शीर्षक से कृष्ण अब द्वारकाधीश, कूटनीतिज्ञ, महाभारत के नायक के रूप में उभरते हैं। यह शीर्षक कथा के चरमोत्कर्ष का केन्द्रीय बिंदु है जहाँ से कथा समापन की ओर आकर विराम लेती है। इतिहास खंड में सात गीत हैं 'विप्रलब्धा', 'सेतु : मैं', 'उसी आम के नीचे', 'अमंगल छाया', 'एक प्रश्न', 'शब्द : अर्थहीन' तथा 'समुद्र-स्वप्न'। 'समुद्र-स्वप्न' की ही अंतिम कड़ी समापन है।

'इतिहास' खंड में राधा का विरह मुखर है। कृष्ण के विरह में राधा अपना दर्प खोती जा रही है। 'विप्रलब्धा' कविता में राधा कहती है—

अब सिर्फ मैं हूँ, यह तन है, और याद है
खाली दर्पण में धुंधला-सा एक प्रतिबिंब
मुड़-मुड़ लहराता हुआ
निज को दोहराता हुआ![26]

'सेतु : मैं' कविता में राधा को इतिहास से शिकायत है, कान्हा से शिकायत है। इतिहास राधा को सेतु बनाकर कृष्ण को उससे छीनकर ले गया—

नीचे की घाटी से
ऊपर के शिखरों पर
जिसको जाना था वह चला गया—
हाय मुझी पर पग रख
मेरी बाहों से
इतिहास तुह्में ले गया![27]

राधा कृष्ण से प्रश्न करती है कि हे कनु, क्या मैं तुह्मारे लिए सिर्फ एक सेतु थी—

सुनो कनु, सुनो
क्या मैं सिर्फ एक सेतु थी तुह्मारे लिए
लीलाभूमि और युद्ध क्षेत्र के
अलंघ्य अंतराल में![28]

कृष्ण के द्वारकाधीश बनने में, सदी के महानायक बनने में बहुत कुछ ऐसा था जो पीछे छूट गया था। राधा उसी छूटे हुए बिंदु पर खड़े होकर कृष्ण से प्रश्न करती है—

तुह्मारे महान बनने में
क्या मेरा कुछ टूट कर बिखर गया है कनु![29]

कृष्ण के जीवन में आए परिवर्तन से राधा के मन में ऐसा बहुत कुछ है जो टूटकर बिखर गया है। राधा अब भी पथ के किनारे खड़े छायादार पावन अशोक-वृक्ष के नीचे कृष्ण की प्रतीक्षा में रोज आती है। आम के नए बौरों के पास हर रोज जाती है किंतु अब उसे वे सब अर्थहीन प्रतीत होते हैं—

नया है
केवल मेरा
सूनी माँग आना
सूनी माँग, शिथिल चरण, असमर्पिता
ज्यों का त्यों लौट जाना...[30]

'अमंगल छाया' गीत में राधा को युद्ध एक अमंगल छाया के रूप में दिखाई पड़ता है जो उसके गाँव पर छा रही है। कवि राधा से कहते हैं कि कृष्ण को पाने के लिए उस कदंब की राह से होकर ना जाना जहाँ कभी ध्यानमग्न कान्हा राधा को बाँसुरी बजा कर बुलाते थे क्योंकि आज उधर से कृष्ण की अठारह अक्षौहिणी सेनाएं युद्ध में भाग लेने जा रही है। यह भारती जी की मौलिक कल्पना है। कवि राधा को समझाता है कि कृष्ण तुह्मारा प्रिय है लेकिन तुह्मारे गाँव को रौंदती ये सेना तुह्में नहीं पहचानती क्योंकि सेना युद्ध का प्रतीक है और राधा प्रेम का पर्याय। स्वाभाविक है कि युद्ध प्रेम के प्रति अपरिचित बना रहे—

उदास क्यों होती है नासमझ
कि इस भीड़-भाड़ में
तू और तेरा प्यार नितांत अपरिचित
छूट गए हैं[31]

राधा कृष्ण के इस स्वरूप से नितांत अपरिचित है। वह तो केवल प्रेम जानती है या उतना ही जितना कृष्ण ने उसे समझाया है। राधा चाहती है कि अर्जुन की तरह कृष्ण उसे भी गीता ज्ञान समझा दे जिससे वह युद्ध, धर्माधर्म, पाप-पुण्य, न्याय-दंड, क्षमाशीलता आदि की सार्थकता समझ पाए—

जितनी समझ तुमसे अब तक पाई है कनु
उतनी बटोर कर भी
कितना कुछ है जिसका
कोई भी अर्थ मुझे समझ नहीं आता है
अर्जुन की तरह कभी
मुझे भी समझा दो
सार्थकता है क्या बंधु ?[32]

'शब्द : अर्थहीन' गीत में राधा कहती है कि इस सार्थकता को तुम मुझे कैसे समझोगे कनु ? क्योंकि ये सभी शब्द मेरे लिए अर्थहीन है—

कर्म, स्वधर्म, निर्णय, दायित्व...
मुझ तक आते-आते सब बदल गए हैं
मुझे सुन पड़ता है केवल
राधन्, राधन्, राधन्
शब्द, शब्द, शब्द,
तुह्मारे शब्द अगणित हैं कनु-संख्यातीत
पर उनका अर्थ मात्र एक है—
मैं, / मैं, / केवल मैं! फिर उन शब्दों से
मुझी को
इतिहास कैसे समझाओगे कनु ?[33]

'समुद्र-स्वप्न' गीत में कवि ने राधा को लक्ष्मी-स्वरूपा दर्शाया है। जो युग-युगों से विष्णु के साथ विराजित हैं। राधा उसी क्षीर-समुद्र को स्वप्न में देखती है। कृष्ण महाभारत युद्ध में जीतने के बाद भी उदास, कभी क्लांत, कभी विस्मित, कभी आहत होकर उसी समुद्र किनारे बैठे हैं। सब कुछ पाकर इतने खिन्न। कृष्ण के मन में अंतर्द्वंद्व है और यहाँ पुरुष पुनः प्रकृति की शरण में जाता है जहाँ प्रकृति स्वरूपा राधा कृष्ण को अपने प्रेम का अभयदान देती है। वह कहती है—

और चारों ओर
एक खिन्न दृष्टि से देख कर

एक गहरी सांस लेकर
तुमने असफल इतिहास को
जीर्णवसन की भाँति त्याग दिया है[34]

उस असफल इतिहास को त्यागने के बाद ही कृष्ण को पुनः राधा की याद आती है—

और अब इस क्षण तुम
केवल एक भरी हुई
पकी हुई
गहरी पुकार हो...
सब त्याग कर
मेरे लिए भटकती हुई...[35]

इसी का विस्तार 'समापन' गीत में होता है। कृष्ण की पुकार पर राधा आती है अपने कनु से मिलने—

और जनमांतरों की अनंत पगडंडी के
कठिनतम मोड़ पर खड़ी होकर
तुह्मारी प्रतीक्षा कर रही हूँ।
कि, इस बार इतिहास बनाते समय
तुम अकेले न छूट जाओ।[36]

राधा कृष्ण से प्रश्न करती है—

सुनो मेरे प्यार!
प्रगाढ़ केलिक्षणों में अपनी अंतरंग
सखी को तुमने बाहों में गूंथा
पर उसे इतिहास में गूंथने से हिचक क्यों गए प्रभु ?[37]

शायद इसी कारण कृष्ण उद्विग्न हो रहे थे क्योंकि राधा के बिना इतिहास कभी पूर्ण नहीं हो सकता क्योंकि प्रेम के बिना शब्द अर्थहीन ही रहते हैं। राधा कहती है—

बिना मेरे कोई भी अर्थ कैसे निकल पाता
तुह्मारे इतिहास का
शब्द, शब्द, शब्द ...
राधा के बिना
सब

रक्त के प्यासे
अर्थहीन शब्द![38]

अतः 'कनुप्रिया' के बिना कान्हा का इतिहास असफल ही रह जाएगा। सारी सृष्टि को शरण देने की सामर्थ्य भले ही कृष्ण में हो लेकिन कृष्ण को शरण देने की सामर्थ्य केवल 'कनुप्रिया' के हृदय में है। इस प्रकार भारती जी ने राधा कृष्ण की पौराणिक कथा को मौलिक परंपरा एवं नवीन बौद्धिकता प्रदान की है। 'कनुप्रिया' युद्ध पर प्रेम की जीत के साथ ही प्रेम का महाराग बनकर दिगंत पर छा जाता है। 'कनुप्रिया' की राधा वर्तमान संदर्भों में नारी चेतना, उसकी शक्ति, प्रेम के विस्तार, राधा की आल्हादिनी शक्ति का विस्तार है। राधा कृष्ण के प्रेम, उनकी लौकिक लीलाओं का अलौकिक विस्तार, पुरुष और प्रकृति के प्रेम का विस्तार 'कनुप्रिया' में सहज रूप से अभिव्यक्त होता है। भारती जी युद्ध की समस्या को प्रेम के दृष्टिकोण से देखते हैं।

Plant Metabolites as New Leads to Herbal Drug Discovery: Approaches and Challenges

Kapish Kapoor, Priyal Jain & Joohee Pradhan

Chapter | First Online: 31 August 2023

247 Accesses

Abstract

Natural products and structural counterparts have long played an important role in pharmacotherapy. Nonetheless, designing novel leads for drug discovery utilising natural chemicals is a difficult challenge. It covers the phytochemical analysis, characterisation, and pharmacological research of bioactive substances originating from natural resources. Because plant-derived metabolites and bioactive chemicals are readily available in a wide range of forms at low cost and do not cause major immune system responses, indigenous wisdom has

a wealth of information about many plants with various medicinal properties. That is why they are a viable and preferable alternative to synthetic substances as therapeutic medications. Drug discovery research requires the development of robust and viable lead molecules that go from a screening hit to a drug candidate by structural elucidation and structure identification using GC–MS, NMR, IR, HPLC, and HPTLC. The discovery of new medications has been transformed by the introduction of new technology for screening natural compounds. Utilising these tools, we will be able to conduct research into new molecule screening using software and databases, establishing natural products as a primary source for drug development. It eventually leads to the identification of lead structures. As research progresses, difficulties are thoroughly investigated in order to overcome the obstacles to obtaining therapeutic plant metabolites and then large-scale production of the same must be designed for industrial purposes. Here, we review recent technological advances that have made natural product-based drug discovery possible, highlight certain applications, and identify major potential.

Phyto-Constituents as Potential Leads for the Development of Novel Antiepileptic Drugs

Joohee Pradhan, Purnima Paliwal, Sunita Panchawat, Rohini Trivedi & Devshree Gayakwad

Chapter | First Online: 31 August 2023

250 Accesses

Abstract

Epilepsy is the major cause of morbidity and mortality despite the availability of varied drugs. The current antiepileptic drugs (AEDs), however, solve numerous problems, but still many adverse reactions are observed in patients for instance; enzyme induction; impact of these drugs on growth and bone metabolism; effect on visual performance, etc. Along with this, the drug resistance epilepsy still remains a problem. Most of the antiepileptic therapies focus on combined administration of two

or more AEDs, but this is still not the solution to existing complications. These facts dictate a clear-cut need of a novel, third-generation, safe, and effective AED. The safety and efficacy of herbal drugs in treatment of various ailments including epilepsy have been supported by a vast literature published time to time. The phyto-constituents present in these herbal sources, e.g., *Bacopa monnierie*, *Acanthus montanus*, *Alchornea laxiflora*, *Berberine*, and many others, were found to act potentially on AED targets, which are voltage-gated Ca^{2+} channel, voltage-gated K^{+} channels (A- or M-type), voltage-gated sodium channel, $GABA_A$ receptors, Nicotinic cholinergic receptors, Glycine receptor, NMDA receptor, AMPA receptor, and ionotropic glutamate receptors, etc. Thus, we have a large database of phyto-constituents, which are effective against various types of epilepsies; and through a systematic approach involving structure–activity relationship study, computational approach such as molecular docking and pharmacophore modeling, new and safer AED can be developed. Along with the pharmacological therapy of Epilepsy and problems associated with the use of AEDs, this chapter includes the antiepileptic activity of various herbal drugs available through literarure. Those phyto-constituents which are responsible for anti epileptic activity, can serve as possible leads for the development of new, safer third-generation antiepileptic drugs.

Alzheimer's & Dementia

THE JOURNAL OF THE ALZHEIMER'S ASSOCIATION

ALZHEIMER'S AND DEMENTIA, (ISSN: 1552-5260), is published monthly on behalf of the Alzheimer's Association by Wiley Perodicals LLC, 111 River St., Hoboken, NJ 07030-5774.

Postmaster: Send all address changes to Alzheimer's and Dementia, Wiley Periodicals LLC, C/O The Sheridan Press, PO Box 465, Hanover, PA 17331 USA. All journals are normally despatched direct from the country in which they are printed by surface air-lifted delivery. All journals are normally despatched direct from the country in which they are printed by surface air-lifted delivery.

Editorial correspondence should be addressed to Donna M. Wilcock: dwilcock@iu.edu

Information for subscribers: Alzheimer's and Dementia is published in 12 issues per year. Institutional subscription prices for 2023 are: Print & Online: US$792 (US and Rest of World), €688 (Europe), £613 (UK). Prices are exclusive of tax. Asia-Pacific GST, Canadian GST/HST and European VAT will be applied at the appropriate rates. For more information on current tax rates, please go to https://onlinelibrary.wiley.com/library-info/products/price-lists/payment. The price includes online access to the current and all online backfiles to for previous 5 years, where available. For other pricing options, including access information and terms and conditions, please visit https://onlinelibrary.wiley.com/library-info/products/price-lists. Terms of use can be found here: https://onlinelibrary.wiley.com/terms-and-conditions

Delivery Terms and Legal Title: Where the subscription price includes print issues and delivery is to the recipient's address, delivery terms are Delivered at Place (DAP); the recipient is responsible for paying any import duty or taxes. Title to all issues transfers Free of Board (FOB) our shipping point, freight prepaid.

Claims for Missing or Damaged Print Issues: Our policy is to replace missing or damaged copies within our reasonable discretion, subject to print issue availability, and subject to the following terms: Title to all issues transfers Freight on Board ("FOB") to the address specified in the order; (1) Freight costs are prepaid by Wiley; and (2) Claims for missing or damaged copies must be submitted by the Customer or Subscription Agent within the claims window, as noted below.

Claims window - General: Claims for missing print issues must be sent to cs-agency@wiley.com (and the Subscription Agent or Customer may be referred to a society) within three months of whichever of these dates is the most recent: date of subscription payment; or date of issue publication.

Claims window - India: Both Subscription Agents and Customers in India have 48 hours after receipt of goods to confirm that all content listed on the packing label has been received. In the event of any discrepancy, SPUR Infosolutions, Wiley's delivery partner in India, needs to be notified within forty-eight (48) hours using this email address: support@spurinfo.com. All claims will be checked against SPUR Infosolutions delivery records before the claim is accepted. The above terms for Wiley's claims policy otherwise apply.

Journal Customer Services: For ordering information, claims and any inquiry concerning your journal subscription please go to https://wolsupport.wiley.com/s/contactsupport?tabset-a7d10=2 or contact your nearest office.

Aims and Scope: The mission of *Alzheimer's & Dementia*: Journal of the Alzheimer's Association is to bridge the knowledge gaps across a wide range of bench-to-bedside investigation. The journal publishes the results of studies in: behavior, biochemistry, genetics, molecular biology, pharmacology, physiology, protein chemistry, neurology, neuropathology, psychiatry, geriatrics, neuropsychology, epidemiology, sociology, health services research, health economics, political science and public policy. Content emphasizes interdisciplinary investigations, integrative/translational articles, related to: etiology, risk factors, early detection, disease modifying interventions, prevention of dementia and applications of new technologies in health services.

Wiley's Corporate Citizenship: Wiley's Corporate Citizenship initiative seeks to address the environmental, social, economic, and ethical challenges faced in our business and which are important to our diverse stakeholder groups. Since launching the initiative, we have focused on sharing our content with those in need, enhancing community philanthropy, reducing our carbon impact, creating global guidelines and best practices for paper use, establishing a vendor code of ethics, and engaging our colleagues and other stakeholders in our efforts. Follow our progress at www.wiley.com/go/citizenship

Wiley is a founding member of the UN-backed HINARI, AGORA, and OARE initiatives. They are now collectively known as Research4Life, making online scientific content available free or at nominal cost to researchers in developing countries. Please visit Wiley's Content Access – Corporate Citizenship site: http://www.wiley.com/WileyCDA/ Section/id-390082.html

Syzigium aromaticum may protect against paraquat mediated toxicity via p53 and Sestrin2 modulation

Nitish Rai[1] | Sharmistha Dey[2]

Abstract

Background: Numerous environmental risk factors, particularly neurotoxins, have been linked to the development of sporadic Parkinson's disease (PD), even though its exact cause is still unknown. The common spice Syzigium aromaticum has the greatest ORAC (Oxygen Radical Absorbance Capacity) value according to the National Institute on Aging. One of the three components of healthy ageing, vata, is calmed by Syzigium aromaticum while also stimulates nerves. The study investigated the rescue effect of Syzigium aromaticum ethanolic extract against paraquat (PQ) mediated PD type toxicity and elucidated the underlying molecular mechanism using the cell line.

Method: The cold extraction method was used to prepare the Syzigium aromaticum ethanolic extract by powdering, soaking in ethanol and stirring for 72 h. Then the supernatant was gradually aliquoted and filtered with Whatman filter paper no 1. Paraquat, at different doses, was used to generate PD type toxicity in SH-SY5Y cells for 24, 48, and 72 hours, and MTT test was used to measure the cytotoxicity. The rescue effect was demonstrated by simultaneously treating cells with 100 mM PQ and various doses of Syzigium aromaticum and then performing MTT assay. The protein expression studies was done using western blot technique to elucidate the underlying mechanism.

Result: The toxicity experiment showed that PQ-treated cells exhibited significant cell death, with the maximal toxicity occurring after 72 hours. However, the cells treated with Syzigium aromaticum were protected from the PQ-induced cell death. Syzigium aromaticum exhibited rescue effect in proportion to its dose. The western blot analysis of PQ treated SH-SY5Y cells demonstrated a dose-dependent increase in the levels of p53, Setrin2, and phosphorylated AMPK (P-AMPK). The levels of AMPK, mTOR and p70S6K remain unchanged, however, the phosphorylated p70S6K (P-p70S6K) levels were declined. When cells were simultaneously treated with PQ and increasing dose of Syzigium aromaticum, the levels of p53, Sesn2, and P-AMPK lowered similar to control. Further, there was an increase in the level of phosphorylated p70S6K (P-p70S6K) in proportion to the dose of Syzigium aromaticum.

Conclusion: The current study showed that the Syzigium aromaticum ethanolic extract prevented PQ-induced cell death in SH-SY5Y by targeting p53 and sestrin2.

1 Introduction

The living beings from the primitive ones to the most developed all require food for their survival and growth. Food being the major component for living is cultivated and harvested throughout the world using various agricultural techniques. For agriculture practice, one requires land which is composed of soil. Hence, it could be said that without the soil, there is no existence of food. Soil has the greatest affinity and dwelling place for a wide range of microflora which in turn is found to be beneficial or harmful, in some cases, for the growth of the plants. The presence or the absence of these microorganisms in the soil totally depends on the soil quality, texture, region where it is present, and the various abiotic factors of that ecosystem. The soil of a specific region may grow certain sort of plant types better as compared to the other soil type since the soil varies from region to region [1]. Soil possesses several vital characteristics and functions such as nutrient recycling, growth of plants and crops, the dwelling place for living creatures, especially microbes, water-holding capacity, filtration, degradation of organic as well as inorganic matter, and many others [1]. Soil serves as the raw material for any kind of agricultural activity in order to produce food or fiber. A soil particle gets surrounded by a large population of microbes in an ecosystem. One gram of soil approximately contains 10 billion bacteria and builds the highest number as well as the biomass of the soil microflora [2].

In India, 60% of the land is under cultivation means that a large population depends majorly on the agricultural produce for their daily requirement of food and feed. Not only India but also most of the countries around the world are

1 Introduction

The microbial community is a major uncovered pool of the Earth's biodiversity, of which only a tiny fraction is known [1]. Microbes comprise the major part of life on the planet and also play a vital role in the life of other living organisms [2]. Nowadays, climate change is appearing as a major issue because it affects life forms on the Earth. These changes are usually seen in the morphology, metabolic rate, photosynthetic rate, activity, and interactions of plant roots with their surrounding plants and microorganisms [3,4]. Growth and development of plants diminishes due to disturbed conditions of soils such as water deficiency, acidity, salinity, shortage of organic and inorganic nutrients mainly essential micronutrients (P, Ca, Mg, and molybdenum). Microorganisms that live in this type of soil enable plants to cope with these conditions [5–9]. The plant roots affect the rhizosphere through the exudation of substances in soil and influence microbial activity. Plant roots offer niches for a multitude of microorganisms, including viruses, fungi, bacteria, protists, and nematodes. Among different phyla, some of the phyla that are included in the plant growth-promoting microbe family are Cyanobacteria, Actinobacteria, Firmicutes, Bacteroidetes, *Bacillus* spp.,

1 Introduction

The world is rich in plant biodiversity and to protect this enormous number of species, many researchers have studied the effects of plant hormones and factors responsible for encouraging and limiting agricultural crop productivity. Eventually, as the research carried further, they discovered many points that have an outcome on plant development in both positive and negative manner such as proper sunlight, water, fertile soil, nutrients, drought, salinity, high temperature, cold, high winds, flood, and pH. Researchers recognized that salinization is the major abiotic stress to the environment [1]. Stress is a limitation that restricts the metabolic processes as well as decreases the ability of plants by converting energy into a nonrenewable energy source [2]. Stress affects one billion hectares of land globally [3]. Salt stress is an undesirable outcome of redundant minerals like Na^+ along with Cl^- or either one of them on the plant [2], and accrual of sodium and chloride ions on the Earth's surface results in natural salinity [3]. An inappropriate practice of irrigation exerts influence on 50% of the total fertile area, which is the major reason for increase in salt concentrations which further cause plant impairment [3]. On the basis of the living world, the quality, and the relation of the plant growth in the salinity area, Szabolcs [4] coined two main types of soils [2], which are as follows: (1) brackish soils—sodium chloride and sodium sulfate are the salts with good solubility, and often this soil

ABSTRACT

The Multidisciplinary Perspectives in Geography

Editor
Dr. Purnima Singh

Contents

S.No.	Title of the Chapter and Author/ Authors	Page No.
1.	Trend of Urbanization and Emerging Environmental Problems in Towns of Rajasthan. –Dr. Preeti Mishra	1-15
2.	Application of Statistical Methods in Applied Economic Geography. –Dr. Nidhi Khinduka Jain	16-24
3.	Geotourism: Future of Travel. – Dr. Ravinder Kumar	25-32
4.	Some Promising Plants in Rajasthan for Phytoremediation. –Bhavika Kunwar and Vartika Jain	33-50
5.	Modern Agriculture Practices and Land Degradation. –Dr Savitri Patidar	51-57
6.	Ecotourism: Conserving Environment with Responsibility. –Dr. Shweta Khandelwal	58-80
7.	History of Lakes of Udaipur. –Rahul Kumar	81-86
8.	Geography as Human Ecology. –Dr. Sandhya Pathania	87-103
9.	Elderly in India: Concerning issues. –Dr. Shruti Tandon	104-111
10.	Feasibility of Wind Energy in Rajasthan. --Dr. Palak Bhardwaj	112-115
11.	भू-सतही जल क्षेत्र में परिवर्तन का भू-स्थानिक अध्ययन: झालरापाटन तहसील, झालावाड़, राजस्थान –भरत कुमार सोनी, निमीष नारायण गौतम, डॉ. शिवानी स्वर्णकार	116-125
12.	मानव पर्यावरण संबंध –डॉ. सबीहा खान	126-136

12. मानव-पर्यावरण संबंध

डॉ. सबीहा खान

सहायक आचार्य, भूगोल विभाग, मोहनलाल सुखाड़िया विश्वविद्यालय, उदयपुर

शोध सारांश

मानव-पर्यावरण संबंध का अध्ययन एक समकालीन विषय है। दोनों घटकों का पूरक संबंध इनके अस्तित्व का प्रमाण है। सौर मंडल के एकमात्र ग्रह - पृथ्वी पर ही मानव जीवन संभव है परंतु इसके साथ ही इसी मानव जीवन के द्वारा ही पृथ्वी के अस्तित्व का महत्व है। मानव, पर्यावरण के प्रत्येक घटक को एवं पर्यावरण, मानव के प्रत्येक पक्ष को सदा प्रभावित करते रहें है और अनवरत करते रहेंगे। प्रागैतिहासिक युग में जहां प्रकृति सर्वोपरि थी एवं मानव अपने जीवन के अस्तित्व के लिए संघर्षरत था। वर्तमान में मानव ने अत्यधिक तकनीकी एवं प्रौद्योगिक विकास के साथ प्राकृतिक घटकों को अपने अनुरूप रूपांतरित करके, अपने जीवन के प्रत्येक पक्ष को मजबूत बनाया है। परंतु प्रकृति के अत्याधिक विदोहन के फलस्वरूप जलवायु परिवर्तन जैसी विकट समस्या ने संपूर्ण विश्व को सोचने पर मजबूर कर दिया है। इस समस्या के निराकरण हेतु मनुष्य को अपनी महत्वाकांक्षाओं पर काबू करना होगा।

कुंजी शब्द: मानव, पर्यावरण, प्राकृतिक घटक, प्रभाव।

मानव पर्यावरण संबंध (Man & Environment Relationship)

मानव पर्यावरण संबंधों का अध्ययन एक प्राचीन विषय के साथ ही समकालीन भी है। मानव सभ्यता के विकास के साथ ही इस प्राकृतिक एवं स्वाभाविक संकल्पना का प्रादुर्भाव हुआ क्योंकि उपलब्ध अनुकूल पर्यावरणीय दशाओं के फलस्वरूप ही मानव सभ्यता का उद्भव एवं विकास संभव हुआ है। बदलते हुए कालचक्र क्रम के साथ ही इस मानव पर्यावरण संबंध के प्रारूपों में परिवर्तन सदैव होते रहे हैं एवं भविष्य में भी होते रहेंगे।

यह संकल्पना विभिन्न वैज्ञानिकों, इतिहासकारों, भूगोलवेत्ताओं, दार्शनिकों के लिए सदैव महत्वपूर्ण विषय रहा है। अतः संकल्पना अंतर विषयक स्वरूप लिए हुए हैं। प्राचीन काल से आधुनिक काल तक यूनानी, रोमन, अरब, भारतीय, चीनी, फ्रांसीसी, जर्मन, ब्रिटिश, रशियन एवं अमेरिकी भूगोलवेत्ता ने इस संबंध में अपने ज्ञान को उजागर किया है। 19वीं सदी के उत्तरार्ध में चार्ल्स डार्विन की पर्यावरण के 'प्राकृतिक चयन' पर आधारित वैज्ञानिक संकल्पना- "विकासवाद सिद्धांत" के साथ ही मानव-पर्यावरण संबंध के अध्ययन का काल प्रारंभ हो गया था।

पृथ्वी पर मानव के जन्म से ही, मनुष्य पर्यावरण को एवं पर्यावरण मनुष्य को प्रभावित करता रहा है। इस संबंध के ऐतिहासिक क्रम पर यदि दृष्टि डाली जाए, तो पाएंगे कि प्रारंभिक काल में पर्यावरण के साथ आदि-मानव का कार्यात्मक संबंध था, जिसमें मानव की भूमिका दो तरफा थी। जहां मानव एक ओर ग्राही के रूप में भौतिक पर्यावरण से अन्य जीवो की भांति विभिन्न प्राकृतिक

Abstract: Various authors have defined a number of the integral transforms in the bicomplex space. This paper presents a review of the research on the bicomplex integral transformations. These transformations' varied applications are also highlighted here. The formula for the bicomplex version of the generalized Stieltjes transform been derived in light of recent advancements in the integral transforms in bicomplex space. Its basic operational properties are also addressed.

Keywords: Bicomplex numbers, integral transform, bicomplex Stieltjes transform.

AMS Subject Classification(2020): 44A05, 30G35.

1 *Introduction*

For a long time, bicomplex numbers have been investigated, and a lot of work has been done in this area. Between 1848 and 1850, Cockle [1, 2] introduced *Tessarines*, after which Segre [3] introduced bicomplex numbers.

Many bicomplex number properties have been identified. Researchers have been studying the various algebraic and geometric features of bicomplex numbers, as well as their applications, for the past few years (see, e.g. [4, 5, 6, 7, 8, 9]). In the recent developments, efforts have been

Abstract

Nanotechnology has broadened its horizon by incorporating nanoproducts in agriculture, as it is the primary source of income in developing nations. These nanoparticles (NPs) are incorporated with conventional fertilizers, fungicides, biocides, pesticides, etc., increasing their bioavailability in soil, sediments, and trophic levels. Various kinds of NPs are used in agriculture, for example, inorganic (Cu, Zn, CuO, ZnO, Fe_3O_4, etc.) and organic. This chapter summarizes, the application of copper-based NPs in agroecosystems. After exposure to the biological system, NPs fate depends on exposure, dissolution, transportation, chemical composition, and interaction with other plants. Their fate can alter depending on the properties of the respective ecosystem they are entering. NPs might aggravate toxic effects on non-targeted plants. Thousands and tons of NPs released into the environment yearly, yet, their interaction with biological systems is needed more systematic and methodical research.

Keywords: Nanotechnology, Copper-based NPs, Agroecosystems, Fate, Bioavailability

Introduction

Advancement in nanotechnology has made advantageous progress in science and technology at the industrial level, especially in biological sciences, agriculture, medicine, computing and microelectronics, environment and bioremediation, chemical manufacturing, transportation, energy, military, and consumer products (textiles, food packaging, cosmetics, paints, etc.). Nanoparticles (NPs) are the particles with at least one dimension in the array of 1-100 nm. These nanoparticles have well-known chemical and physical properties comprising antimicrobial and biocidal, photovoltaic and superconductivity, and relative stability by boosting the effectiveness of the products despite their small size. Extensive usage of nano-based agriproducts to control pests and improve fertility and growth has waked researchers to dwell

Abstract: - Nanotechnology is science, engineering, and technology conducted at the nanoscale which is about 1-100nm. Different techniques are there to synthesize the nanoparticles and modify them as per requirement. The types of nanoparticles and their enormous number of applications have crucial importance in the emerging field of nanotechnology. Although it's an emerging field but has less knowledge about the behaviour of nanoparticles which can lead to the generation of nano waste which may cause an adverse impact on the environment.

Keywords: - Nanotechnology, engineering, technology, nanoparticles, nano waste.

Introduction: -

Nanotechnology and nanoscience are emerging areas with enormous potential to enhance many areas of study and applications. What is truly novel about nanoscience is that developments in material science and characterisation technologies now allow for monitoring materials at the nanometre (nm = 10^{-9}m) scale, allowing for unique insights into atomic interactions [1]. Nanomaterials (NMs) are defined as materials that have particles with at least one dimension of 1-100 nm in length. Their unique physical and chemical properties have made them advantageous in a variety of applications [2]. Depending on the overall shape these materials can be 0D, 1D, 2D or 3D [3]. Nanoparticles have an interesting history. Their production is not solely the outcome of current science, nor is it limited to man-made materials. Organic nanoparticles (proteins, polysaccharides, viruses, among others) and inorganic nanoparticles (iron oxyhydroxides, aluminosilicates, metals, among others) are created naturally by weathering, volcano eruptions, wildfires, or microbiological processes [4]. The production of nanoscale materials with unique physicochemical properties has resulted in powerful nanotechnology in the twenty-first century, allowing existing technologies to realize their full potential. The unique features of these

Abstract:

Industrial effluents are one of the major provenances of continuous input of pollutants in aquatic ecosystems. The treatment of such contaminated systems requires several techniques, which include both conventional methods and some special techniques. Phenolic compounds are one of the persistent and lethal components found in wastewater. The contamination due to phenol and its compounds has moderately appeared. The degradation of such compounds can be achieved by using solar energy. Photodegradation or photolysis is a significant process in which pollutants are disclosed to sunlight. The process of photodegradation is enhanced by utilizing photocatalysts, which are regularly modified by incorporating nanoscience. Several physiochemical and biological methods have been developed which are environment friendly and bring complete mineralization of toxic compounds. Researchers have proved that several microorganisms can transmute organic pollutants into simpler compounds. Such methods proved sustainable and cost-effective.

Keywords: Phenol, Phenolic compounds, wastewater, physiochemical methods, biological methods.

Introduction:

Phenol is a crucial material in industries and is generally used in petrochemical industries, medicine, pesticide, dye, paper, and coal industries. Phenol acts as a forebearer in the production of several pharmaceutical drugs, plastics, epoxies, polycarbonates, and detergents. Its extensive use and noxious nature have generated serious health issues, as well as contamination of soil and water[1]. The carcinogenic and mutagenic effects affect humans, plants, and animals even at a very low concentration level[2]. In aqueous environments, the presence of phenol creates serious problems because of its perseverance and toxicity. Due to its carcinogenic nature, phenol causes mouth sores, darkening of urine, blood diarrhea, nausea, and vomiting with varying levels[3]. On top of that, while

Abstarct

Photocatalysis is a promising method for eradicating organic dyes from wastewater. Among the admired photocatalyst, copper oxide nanoparticles (CuO-NPs) are widely used for the photodegradation of organic dyes in wastewater treatment due to their low cost, abundance, less-toxic, ability to proceed at ambient temperature, and high photonic efficiency. This chapter includes a brief overview of dyes as a pollutant, applications of dyes, and dyes classification. Further, the photodegradation mechanism of dyes and kinetics using CuO nano photocatalyst is also discussed. It emphasizes the operational parameters affecting the photodegradation of cationic or anionic dyes and the charge carrier properties of the CuO nanocatalyst under visible or UV irradiation. In addition, we have discussed the photodegradation of organic dyes such as anionic dyes- methyl orange (MO) and congo red (CR) and cationic dyes- methylene blue (MB) and rhodamine B (RhB) using CuO nano photocatalyst.

Keywords: Copper oxide nanoparticles (CuO-NPs), photocatalyst, organic dyes, photodegradation, scavengers

1 Introduction

Ironically 'there is a reason we don't see the world black and white.' (Celeries Kemble)

Colours have always fascinated human beings since the Neolithic period (6000-3500 BC) from cave painting to acrylic advancements [1], [2]. Back then, a few plant-based colourants such as madder, indigo, woad, and saffron were cultivated and used as trade-in economies over Europe and the Asian continent especially. The use of these natural colouring agents came to a check, after the discovery of synthetic dyes by William Henry Perkin in 1856 [3]. This was one of the revolutionary works done in organic chemistry with its economical applications. Synthetic dyes are the most important colouring agent used in

Editors' Introduction

Dr. Om Prakash

M.A., Ph.D. in Geography from Jai Narain Vyas University Jodhpur, UGC NET-JRF in Geography, UGC NET in Population Studies, RPSC SET in Geography, NNRMS certificate course IIRS-ISRO. He has been working as an Assistant Professor in the Department of Geography at Jai Narain Vyas University, Jodhpur since 2013. He is also the coordinator of the Nodal Centre for the IIRS outreach program. At present, four research scholars are pursuing PhDs under his supervision. He has participated and presented papers in various international and national seminars and conferences and has published many research papers in reputed journals.

Dr. Gaurav Kumar Jain

M.A., M.Phil., NET-JRF, RPSC-SET in Geography, Ph.D. from Jai Narain Vyas University, Jodhpur. He has been working as an Assistant Professor in the Department of Geography at Jai Narain Vyas University, Jodhpur since 2013. At present, five scholars are pursuing research degrees under his supervision. He has participated and presented papers in various international and national seminars and conferences and has published many research papers in reputed journals.

Mr. Govind Singh

M.A. UGC-NET in Geography, RPSC-SET in Geography and Population Studies both. Born in 1983 in the village of Bhawanda in the Nagaur district of Rajasthan. Vagdevi's spiritual practice and literary interest turned him towards writing. He has a spontaneous inclination towards poetry, drama and various co-curricular activities. Due to his deep interest in geographical analysis and culture writing, various research articles and contemporary papers have been presented as well as published in various journals by him. He has been working as an Assistant Professor at the Department of Geography at Jai Narain Vyas University, Jodhpur since 2013.

Dr. Lalit Singh Jhala

M.A., NET, SET, Ph.D. in Geography from Mohan Lal Sukhadia University, Udaipur. Currently, he is working as an Assistant Professor in the Department of Geography at Jai Narain Vyas University, Jodhpur. His books, titled "Regional Disparities in Tribal Area" (single author) and "Tourism Development in Desert and Humid Zones" (co-authored), were published in 2012 & 2016 respectively. Dr. Jhala, is the recipient of the "Young Geographer Award" (2008) at the Rajasthan Geographical Association (RGA) national conference. He has also served as the Vice-President of RGA from 2020 to 2022. He has participated and presented papers in various international and national conferences, seminars and workshops; and has published 15 research papers in reputed journals. He has also supervised four Ph.D. scholars from Mohanlal Sukhadia University, Udaipur and JNV University, Jodhpur, respectively.

Preface

Climate change has become an agenda of key concern and requires our utmost attention. There are several factors which collectively attribute to climate change but anthropogenic activities since the early 1700s, could be considered the major cause of it. These anthropogenic activities not only degrade the quality of the water, air and soil around it, but are also responsible for several adverse health effects on animals and humans. Recent accelerated climate change has exacerbated existing environmental problems around the globe that are caused by the combination of changes in land use, increasing pollution and declining biodiversity. Climate change can be said to be a threat multiplier. It intensifies existing threats, aggravating complications for the environment, economy and thus, the entire society. The recent global warming is already producing negative influences on natural and human systems, seriously impeding progress toward some sustainable development goals (SDGs). Sustainable development is development that meets the needs of the existing generation without compromising with the capabilities of the future generations to meet their own needs. Climate change causes hindrance in the sustainable development of the society which not only affects mankind but all the species existing in an ecosystem.

This bilingual book emphasises on the several issues regarding climate change and how these issues are interlinked with sustainable development. The 20 chapters of this book revolve around how plants and animals are affected by climate change and how they can be used as indicators of climate change, how the agriculture sector is affected by it and what policies could be brought into account to stop the climate change and lead to betterment of all via working on sustainable development goals.

We would like to thank all the authors for coming forward and presenting their ideas which helped us in moulding this book. Their efforts would help the present and future generations in understanding the importance of this topic and would open gateways of new and better research.

Foreword

Earth, life and climate have always changed and climate change itself may have been crucial for the evolution of human being. The climate system is a complex interactive system consisting of the atmosphere, hydrosphere, lithosphere, cryosphere and outer space. Climate change is a global challenge with diverse implication at the national and regional levels, through impacts on various sectors such as agriculture, water resources, forestry and biodiversity, human health, energy and infrastructure. The scientific studies indicate that climate change is inevitable. The climate has transformed in the past, is varying in the present and is bound to change in the future. Today we are erroneously worried about the global warming and the impacts it is likely to bring. Contrary to it, some scientists forecast that 'global cooling' would be more disastrous in future.

The scientists are debating on the causes of climate change. The natural scientists believe that climate changes are due to several natural forces like changes in the obliquity of earth's axis, its rotational speed, solar variability or sunspot and volcanic activities. On the contrary, some scientists who believe in global warming say that increase in the emission of green house gases after industrial revolution has been mainly responsible for global warming and climate changes. It is beyond doubt that since 1850 A.D. the temperature is rising at such a rate that it was never experienced during last 800,000 years during geological past. The 'pro-warming lobby' advocates that the earth's warming occur not only in response to external forcing but also due to release of GHG's in the atmosphere by human beings especially the burning fossil fuels.

This book **"Climate Change and Sustainable Development"** presents a systematic work on the issues of climate change. The backdrop ranges from biology, agriculture, renewable energy to human health. All of these are very important aspects of human life as impacted by the rapid change in the climate of the earth. The book offers a wide variety of topics ranging from the global scenario of climate change, the bio monitoring properties of a plant that can be symptomatic of climate change and its impacts, the issue of solid waste management, the problems of agricultural pollution, the scenario of potential and challenges of biomass energy. The wider academic and geographical area of the problems discussed in the various chapters ensures that the book is wide in its scope, methods, approaches, spatial coverage and variety of problems faced.

I take immense pleasure in congratulating all the editors, as well as, the contributing authors of this book. The editors **Dr. Om Prakash, Dr. Gaurav Kumar Jain, Mr. Govind Singh and Dr. Lalit Singh Jhala** have, through persistent hard work and academic assiduity produced a well-balanced piece of literature that is varied in its approach and perspectives.

Hence, my compliments for their ardor and zeal.

Climate Change: An Overview of The Global Scenario

Bhavya Singh[1], Chirmaie Nagda[1], Kapil Kumar[1], Monika Rathore[1], Girima Nagda[2], Lalit Singh Jhala[3] and Devendra Singh Rathore[1]*

Abstract

Climate change is the variability among climatic statistics such as temperature, precipitation, wind circulation patterns, oceanic currents, and hot and cold snaps. Climate phenomena are accelerating at an alarming pace due to anthropogenic forces. It's a global pandemic of the 21st century that demands to act collectively in unison to curtail the changes that adversely affect the environment and the climate. These global alterations pose a threat to Earth and earthlings due to over-flourishing industrialization, unplanned development, and degradation of forests, population explosion, over-exploitation of natural resources, and increased pollution concentration in an ambient environment. Outcomes of these anthropogenic driven forces are devastating and detrimental, which speeds up the ecosystem disruption to its collapsing level. These events are impacting the ecosystems, ecological niches and habitats, shifting of geographical realms, altering weather patterns, sea level upsurging, melting of permafrost, biodiversity, changing hydrological and nutrient cycling, reducing ecosystem services, the outbreak of diseases, nations economy, and lives and livelihoods of people, etc. around the planet.

Keywords: Climate change, GHGs (Greenhouse gases), climatic systems, earthlings, pandemic, global, threats, over-exploitation.

Introduction

Climate change has become a crucial concern around every corner of the globe, which must be discussed and mentioned at the scientific and academic level and the societal level from a broader perspective as these climatic events worsen in the 21st century. Climatic changes across the globe have escalated the frequency and magnitude of altered unprecedented events such as wind circulation patterns across the northern and southern hemispheres, oceanic flow from equator to poles, and greenhouse gas

[1*] Corresponding author

concentration in the ambient atmosphere. The events mentioned above cascading detrimental effects on Earth and earthlings in varied ways, for instance, affect and impact the life and livelihoods, biodiversity, seasonal variations, local weather patterns, freshwater availability, energy, and food security, etc. by altering the ambient environment. We are now getting used to this climate emergency as we have seen and heard about it everywhere. But, do we care about this climatic emergency?

Climate is an ancient Greek word that means ***Klima***, meaning inclination. Climate is simply the standard average of 30 years of weather over a long period of any considered/studying area. According to IPCC (Intergovernmental Panel on Climate Change), 2001 glossary:

Climate in a narrow sense is usually defined as the "average weather," or more rigorously, as the statistical description in terms of the mean and variability of relevant quantities over a period ranging from months to thousands or millions of years. The classical period is 30 years, as defined by the World Meteorological Organization (WMO). These quantities are most often surface variables such as temperature, precipitation, and wind. Climate in a wider sense is the state, including a statistical description, of the climate system. (IPCC, 2001). The World Meteorological Organization (WMO) describes ***climate "normals" as"reference points used by climatologists to compare current climatological trends to that of the past or what is considered 'normal'. A Normal is defined as the arithmetic average of a climate element (e.g. temperature) over a 30-year period"*** (WMO).

Earth's climate comprises of five main climate systems, which are atmosphere (air), hydrosphere (water), cryosphere (ice and permafrost), lithosphere (upper earth layer, i.e., soil/land), and biosphere (living entity). The industrial revolution started back in the 1950s has gradually escalated the ambient atmospheric temperature, which has reached a level that is massively contributing to global climate change. The industrialization has popped up the concentration of atmospheric greenhouse gases to many folds than pre-industrialization. Climate change is a remarkable long-term change across the globe. Climatic changes are paving their way beyond thermal stress, disrupting ecosystems, and influencing the resources we depend on for our daily lives, such as water, energy, transportation, wildlife, agriculture, forest, and human health. Climate is one of the most important factors that affect species behavioral, productivity and distribution, and has an enormous impact on habitat and ecosystem ecology.

India is the 2nd most populated country with 1.3 billion population and lies at 6^{o} 44' and 35^{o} 33' latitude and 68^{o} 71' and 97^{o} 25' longitude. It's a mega-diverse nation. India is exceptionally prone to climate change impacts mainly due to its unique geography (IPCC, 2017). According to Global Climate Risk Index 2020, the top 10 most affected countries in 2018 are Japan, Philippines, Germany, Madagascar, India (14 in 2017), Sri Lanka, Kenya, Rwanda, Canada, and Fiji in chronology (Eckstein et al., 2019).

Climate change is the outcome of global warming due to the excess release of GHGs (Greenhouse gases). Global warming is the warming or heating up of Earth's environment naturally. But what we did is accelerate this gradual heating process and make the Earth's temperature rise by 2-3^{o} Celsius. Since the pre-industrial period, anthropogenic greenhouse gases emissions have risen significantly propelled by economic and population growth, and nowhere are they: at their peak. This has

contributed to unparalleled atmospheric amounts of CO_2 (Carbon dioxide), CH_4 (Methane), N_2O (Nitrous oxide), as well as some anthropogenic induced gases such as HFCs (Hydro-fluoro carbon), PFCs (Perfluorocarbon), and SF_6 (Sulfur hexafluoride) over the last 100 years. The impacts were found in the climate system and other human-driven forces and were likely to be the primary cause of the observed warming since the mid- 20th century. Global warming has the potential to induce extreme, pervasive, and irreversible impacts with greater magnitude in the future.

The CO_2 concentration in Earth's atmosphere has increased from pre-industrial time and has reached 405ppm (Parts Per Million) in 2017 to 414.11ppm in February 2020, the concentration of methane was 1849.95 ppb (Parts Per Billion), and nitrous oxide was 330.30 ppb in the year 2017 (NOAA). According to WMO (World Meteorological Organisation), since 1990, the warming consequences of stable greenhouse gases on our planet have risen by 41% (WMO). 2019 was the second warmest year measuring Earth's average global surface temperature at 1.71° F (0.95°C) of the 20th century. After 2005 nine of the ten warmest years on record have taken place (NOAA).

First-time climate change was addressed at the first earth summit, i.e., the Rio convention in 1992 held in Rio de Janerio adopted by UNFCCC (United Nations Framework Convention on Climate Change). UNFCCC came into force on 21 March 1994. The primary objective of this conference was to stipulate greenhouse gas emissions at a level that would prohibit the release of harmful anthropogenic driven gases entering into climate systems

The Inter governmental Panel on Climate Change (IPCC) has already forecasted in its 'Fifth Assessment Report' released in 2014 that threats associated with extreme events will continue to increase as the global mean temperature rises. IPCC is a United Nations governing body established in 1988 by WMO (World Meteorological Organisation) and UNEP (United Nations Environment Program). It produces reports which contribute to the work of UNFCCC**.**

"IPCC prepares comprehensive assessment reports on the state of scientific, technical and socio-economic knowledge on climate change, its impact and future risk and options for reducing the rate at which climate change is taking place." IPCC has been assigned to prepare a document on climate change, a detailed description of scientific assessment covering a broad spectrum of aspects of climate change, its impacts, and its variability.

Effects of climate change

Climate change affects every arena globally, mainly social, economic, and cultural aspects, at an alarming pace. Climatic events surpassed in the last 2-3 decades, affecting billions of people's lives, biodiversity, retreating glaciers, coral reefs, agricultural and food industry, forest, economy, etc. Increase in average global temperature since the pre-industrial era has substantially increased the frequency of storms, wildfires, cyclones, heatwaves, desertification, floods, droughts, famines, lowering of groundwater level, sea-level rise, disrupting wind and ocean currents, seasonal variations, crop patterns and production, depleting forest cover, the breakout of deadly diseases, increasing pests, affecting livelihoods of coastal region people, etc.

Greenhouse gas emissions were the largest in 3 million years when the Earth's

temperature was 3 degrees higher and the sea level 15 meters higher, which leads to the loss of earthlings and their livelihoods from droughts, wildfires, floods, severe storms, freshwater, and air crisis as well as a breakout of deadly diseases. State of the climate report 2019 emphasized the substantial effects of climate change such as thermal stress rising between land and ocean, upsurged sea levels, retreating glaciers as well as their influence towards socio-economic growth, human health, migration and relocation, food and water security, and land and marine ecosystem (WMO).

Effect of climate change on the coastal region

Corals are key indicator species for the health of the marine ecosystem worldwide. Approximately 50-70% of coral reefs are directly impacted by human-driven global climate change (Hoegh-Guldberg, 1999). Over the years, however, an inflated demand for coastal and marine goods and services ended in the unacceptable depletion of such vital assets, thereby diminishing the potential of those habitats themselves. Coastal erosion, beach erosion, damaging the flood management protection of coastal areas, loss of biodiversity has affected the livelihood and economy of agricultural, forestry, and fisheries dependent sectors. Coral reefs went through dramatic destruction because of varied anthropogenic and natural events in the last 3-4 decades. Coral reefs are a highly bio-diversified ecosystem on Earth, home to several species globally, and provide a livelihood to approximately 500 million people in economically poor countries or developing nations (IUCN).

Coral reefs host more than one-quarter of overall marine fish species (according to other marine species) despite covering less than 0.1% of the ocean floor (Spalding et al., 2001). Coral bleaching could recover if rising sea temperature between 1-2^{o}C normalizes within some days. If this temperature rise persists for a longer duration, it will lead to coral death. 24% of coral bleaching was observed with 16% of mortality, which has reduced 23% of coral cover in India between March to June 2016 in Gulf of Munnar (Down-to-Earth, 2018). Coral mortality deviates as per species variability and varied responses towards climatic events; for instance, fast-growing coral species *Acropora, Montipora,* and *Pacillopora* faced severe mortality due to resistance towards temp rising. In 2010 and 2016, coral bleaching caused severe mortality in the wake of global climate change (global coral bleaching events). SAC (Space Application Centre) produced an alert report on coral bleaching. They evaluated the mass bleaching in 1998, 2010, and 2016 in 5 coral reefs of India, i.e., Andaman, Nicobar, Gulf of Kutch, and Gulf of Munnar (Down-to-Earth, 2018)

Corals are deteriorating by cascading climatic events occurring in the last 2-3 decades, for instance; increase in temperature (1-2°C), light level/high solar irradiance, salinity, and low water quality due to agricultural and storm run-off other pollutants, acidification due to elevated CO_2 levels in oceans. The ocean absorbs around 30% of the world's carbon dioxide, which is being released into the atmosphere from the burning of fossil fuels by various sectors. This, in turn, is accelerating the acidification of oceans damaging marine life to a great extent. The increase in sea level will result in the influx of salt water and salinity of groundwater and surface water in coastal regions. Saltwater in agricultural plains may lead to food shortages, further spread of water-borne diseases, and lack of freshwater supply (Climate Change Report, 2009).

Effects of climate change on glaciers

Global climatic patterns have significantly impacted the Himalayan glaciers leads to the melting of ice caps since post-glacial time. Most of the river system is originating from the Himalayas Karakoram Range in India is home to almost 13,700 glaciers. Sea level is rising due to the melting of glaciers, the reason being global warming (warming air and increasing ocean temperature) which is cascading other disruptions, for instance, coastal erosion and storm surges (hurricanes and typhoons), as well as showing detrimental effects on the livelihoods of downstream people. Thawing of glaciers due to thermal distress and retreating land ice sheets has led to a rise in sea level, which has posed a severe threat of erosion and storm surge.

As surveyed by the Geological Survey of India, the glaciers of Satluj river basins such as Gara, Gor Garang, Shaune Garang, NagpoTokpo retreated at an average rate of 4.22-6.8m/year. At the same time, the Chenab river basin glaciers such as Bara Shigri, Chhota Shigri, Miyar, Hamtah, NagpoTokpa, Triloknath, and Sonapani retreated at an average rate between 6.81-29.78m/year. It can be concluded from above that the Bara Shigri glacier and Chhota Shigri glacier were recorded as the highest and lowest retreated glaciers (Vohra, 1981). Vohra (1981) monitored the Siachen and Pindari glaciers retreated with the rate of 31.5m and 23.5m/year. Thakur et al. (1991) found that the Gangotri glacier has retreated at the rate of 18m/year. Shukla and Siddiqui (1999) evaluated the 9.1m/year retreating rate for Milam Glaciers in the Kumaon Himalaya. Matny (2000) evaluated that Dokriani Bamak glaciers retreated at a rate of 20m compared to the average rate of 16.5m over the span of 35 years. Dobhal et al. (1999) observed the shifting of the Dokriani Bamak glacier by 586m in Garhwal Himalayas from 1962 to 1997.

Philip and Sah (2004) studied the Shaune Garang Glacier, which has shifted its place vertically by 100 m and similarly shifted horizontally by 1500m in 37 years. From 1780 to 2001, the Gangotri Glacier snout was moved around 2 km vertically and changing its place continuously. Kulkarni and others observed the retreating of many glaciers such as Janapa glacier by 646m, Jorya Garang by 425m, Naradu Garang by 550m, Bilare Bange by 90m, Karu Garang by 800m, Baspa Bamak by 380m, and Parbati Glacier in Kullu district by 608km from 1962 to 2000. They also concluded that in 39 years, the glaciated area was retreated by 19% and glacier volume by 23% (Kulkarni et al., 2004). In the Himalayan region, GLOF (Glacial Lake Outburst Flood) observed every 3-10 years resulted in the loss of lives and damaged the roads, houses, forests, bridges, and fields (Bajracharya et al., 2008)

Effects of climate change on agriculture

In India, 15% of GDP coming from the agricultural sector (other than forestry and fisheries), which engages 55% of the labour force. Furthermore, according to the 2011 census, 69% of the rural population is still closely associated with this sector. The rest of the economy also has significant forward and backward linkages with agriculture (Gupta et al., 2012). Around the world's one-third of the land area comes under cultivation. Agriculture in India is dependent on optimum weather conditions as crops are produced seasonally, such as Rabi and Kharif crops. Climate change brings altered rainfall patterns, thermal stress, proliferates pests and diseases and, irregular

crop cycle leads to a reduction in plant growth and yield.

A rise in the winter temperature of 0.5° Celsius is expected to decrease the wheat yield by 0.45 tons per hectare. A recent World Bank study analyzed the impacts of climate change on two drought susceptible regions in Andhra Pradesh and Maharashtra and one flood susceptible area in Orissa and concluded that Dryland farmers in Andhra Pradesh could see their income plummeting by 20%, sugarcane produce in Maharashtra can drop drastically by 25-30% and in some districts of Orissa substantial increase in floods leading to declining in rice production by 12% (Guiteras, 2009). Guiteras (2009) studied the effects of changing climatic variables such as temperature and precipitation in overall out-turn for rice, wheat, jawar, bajra, maize, and sugarcane. He depicted that without proper adapting and mitigating strategies, these alarming changes over the globe can decrease the out-turn by 4-9% in the short-run (2010-39) and by 25% in the future (2070-2099).

Effects of climate change on biodiversity

Climate change is a significant threat to biodiversity, rising pressure on genetic diversity, communities, and ecosystems. As per the report of the Ministry of Environment, Forest and Climate Change, India, a mega-diverse nation that contributes 7 to 8% of documented species, including 45,000 species of plants and 91,000 species of animals worldwide through India only accounts for 2.4% of the global area. India is among the 17 mega-diverse countries home to many plants, birds, fishes, mammals, reptiles, amphibians, insects species, and microorganisms (MOEFCC, 2014). Changing in climatic systems such as pollution, overpopulation, anthropogenic emissions, overexploitation of natural resources, heat storms, land-ocean thermal stress, droughts, floods, cyclones, seasonal variations, sea-level rise, coastal upwelling, rising of ambient temperature, annual and seasonal precipitation variations, changing intensity and frequency of solar irradiance and soil erosion, etc. are directly affecting the growth, habitats, reproduction, breeding seasons, migration of biodiversity.

Bates et al. (2008) stated that habitat loss in the wake of changing climate might severely affect approximately 5,000 plant species Thuiller (2007) mentioned that every 10□ increase in temperature would cause the occurrence zone of several specialist species to move by 160 meters vertically and 160km horizontally. Around 27,000 specioes are expected to become extinct every year. If thuis continues, 30 percent of the world's animals by the year 2050 will become extinct. The global rate of extinction is 100 to 1000 times that of natural death. Invading species (*Lantana camara, Partheniumhys terophorous, Ageratumconyzoides*) are dangerous to more climate-tolerant native species. Seasonal changes due to ever-increasing climatic conditions affect the normal plant life cycle by changing leaf fall, bud formation, flowering, fertilization, synchrony during pollination, fruiting and production, etc. Early flowering, fruiting, and ripening in crops showed less grain production. Due to the increase in land thermal stress, forest fires have escalated in recent years (Sharma, 2011)

In its most recent evaluation, the IPCC underlines that 20-30% of the species assessed so far are likely to be at increased risk of extinction if global average warming increases by 1.5-2.5°C (relative to 1980-1999). If global average temperature

increases around 3.5°C, 40-70% of the species assessed become extinct majorly across the globe (IPCC, 2001). As a result of high ocean thermal stress, more female turtles are produced than male turtles. As well as some threatened species, e.g., elephants, frogs, toads, amphibians, and tigers, are more prone to vulnerability due to climate change. Some findings observed the decreased weight of the polar bears from 325kg to 253kg between 1980 to 2004 (Bellard et al., 2012).

Parmesan (2006) and Bellard et al. (2012) confirmed that climate change is responsible for significant consequences throughout various biodiversity levels such as genetic, species, organismal, and ecosystem. Some species, such as *Berberisasiatica, Taraxacumofficinale*, *Jasminumofficinale,* etc., have moved to the elevation from 1000 to 2000m in Nanital (Anonymous, 2009).

Effects of climate change on humans

Climate variability impacts the human race and generates interfering warming pressure by increasing morbidity and mortality. Climate change can directly affect human health, such as thermal stress, cold snaps, death/injury during floods and storms, and indirectly through disease-spreading vectors, e.g., mosquitoes, viruses, bacteria, and various pathogens. The local environment, social, behavioral, and economic aspects are strongly influenced due to climate variability. The numerous health effects such as traumatic, infectious, nutritional, and psychological and other that emerge in shells hocked and distress communities amid climate induced economic dislocation, environmental degradation and conflict.

Changing climate is affecting all the species on our planet. Even the human race cannot withstand this ever-increasing climate crisis persistently for the last 50 years. Climate crisis brings our notice to breaking out diseases such as dengue, malaria, plague, Ebola virus, Nipah virus, Zica virus, etc. Recently COVID-19 (Coronavirus disease 2019) outbreak in central china has spread its roots across the globe as a pandemic leading to active cases toll 191,733,410 and death toll is 4,113,054 last week of July, 2021 (WHO, 2021). This disease is very contagious and transmits through contact from patients to their caregivers.

As a whole, 12000 severe weather incidents worldwide leads to 4 95,000 causalities between the years 1999 and 2018, which costs up to US$3.54 trillion. The annual monsoon in 2018 hit worst over hundreds of years, and it devastated Kerala state severely, which damaged 80 dams, 20000 houses with 324 causalities, and 2,20,000 people were forced to vacate their abode primarily due to flooding, which costs up to EUR 2.4 billion (US$ 2.8 billion). Moreover, Cyclone Titli and Gaja hit the east coast of India in October- November 2018 with 150km/h wind speed leads to 8 deaths and set off 4,50,000 without electricity. As per the Global Climate Risk Index 2020, in 2018, a sum of 2,928 people officially died from heat-related impacts, compared to 3,622 causalities due to flood and 2,463 death tolls from extreme storms (Eckstein et al., 2019). According to the MOEFCC report, around 2400 casualties occurred in the year 2018-2019 due to consecutive floods and cyclones in the face of altered meteorological systems. India recorded a temperature near 50°C; this intense water stress was omnipresent. Because of droughts in Chennai, around a million occupants could only be provided with water by trains and trucks.

Effects of climate change on the economy

According to a Stanford report showing that how Earth's increased thermal stress has raised disparity, global warming has slowed down the Indian economy by 31% (Economic Times). Over the last 15 years (2005-2019), the U.S. has endured 156 different weather or climate disasters causing a combined $1.16 trillion over damages (NOAA). As per Global Climate Risk Index 2020, India's death tolls are 2081, and total losses in US$ 37807.82 million (in PPP- Purchasing Power Parities). The IPCC evaluates in its current report on "Global Warming of 1.5°C that the "average net cost of the warming risk at 1.5°C and 2°C in 2100 (Mention global warming-induced business and non – business effects, seal level effects, and significant spectrum discontinuity effects) is US$ 54 trillion and US$ 69 trillion, significantly, concerning 1961-1990. Existing figures for potential losses and mitigation needs for climate finance spectrum between US$ 290 billion to US$ 580 billion in 2030. As forecasts in UNEP (United Nations Environment Programme) Adaptation Gap Report 2016, that expenditure for global climate change adaptation strategies will be accelerating by twice to thrice fold for the year 2030 and four to fivefold for the year 2050 than the current scenario. In 2018, heat resulted in a total cumulative loss of US$ 60.42 billion (in PPP) worldwide (Eckstein et al., 2019).

Conclusion

This ever-increasing global warming has paved its way towards extreme climatic changes around the globe, and it's knocking–off the unprecedented events over India and the world. These variations have increased the frequency and magnitude of wind patterns, cold waves, ocean currents, cyclones, EL-Nino, La-Nina, droughts, hot spell winds, famines, precipitation, thermal stress, shifting of geographical realms, and a severe scarcity of water and food which is in turn affecting the earthlings at genetic, species, population and, community level by curtailing their livelihoods, growth, reproduction, mating, reducing their geographical territory, depleting water regimes, degrading ecosystems and ecosystem services as well as increasing morbidity and death toll. It's an urgency to think about the possible solution not just virtually but practicing all the possible solutions at the grass-roots level individually and collectively to reduce the magnitude of these extreme harsh events before it's too late to survive. We need to takes action at full-tilt because climate change would not wait for our preparedness. 2030 and 2050 agenda to reduce global emission by 2-3° C is necessary to achieve before time to delay the next mass extinction.

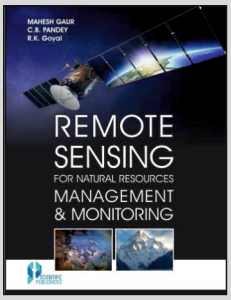
Lalit Singh Jhala



Climate change has become an agenda of key concern and requires our utmost attention. There are several factors which collectively attribute to climate change but anthropogenic activities since the early 1700s, could be considered the major cause. Climate change causes hindrance in the sustainable development of the society which not only affects mankind but all the species existing in an ecosystem.

This book highlights the connection between climate change and sustainable development, exploring the impacts of climate change on the environment, economy, and society. It is a result of contributions from multiple authors, aimed at raising awareness and encouraging further research on the topic.

Editors' Introduction

Dr. Om Prakash

M.A., Ph.D. in Geography from Jai Narain Vyas University Jodhpur, UGC NET-JRF in Geography, UGC NET in Population Studies, RPSC SET in Geography, NNRMS certificate course IIRS-ISRO. He has been working as an Assistant Professor in the Department of Geography at Jai Narain Vyas University, Jodhpur since 2013. He is also the coordinator of the Nodal Centre for the IIRS outreach program. At present, four research scholars are pursuing PhDs under his supervision. He has participated and presented papers in various international and national seminars and conferences and has published many research papers in reputed journals.

Dr. Gaurav Kumar Jain

M.A., M.Phil., NET-JRF, RPSC-SET in Geography, Ph.D. from Jai Narain Vyas University, Jodhpur. He has been working as an Assistant Professor in the Department of Geography at Jai Narain Vyas University, Jodhpur since 2013. At present, five scholars are pursuing research degrees under his supervision. He has participated and presented papers in various international and national seminars and conferences and has published many research papers in reputed journals.

Mr. Govind Singh

M.A. UGC-NET in Geography, RPSC-SET in Geography and Population Studies both. Born in 1983 in the village of Bhawanda in the Nagaur district of Rajasthan. Vagdevi's spiritual practice and literary interest turned him towards writing. He has a spontaneous inclination towards poetry, drama and various co-curricular activities. Due to his deep interest in geographical analysis and culture writing, various research articles and contemporary papers have been presented as well as published in various journals by him. He has been working as an Assistant Professor at the Department of Geography at Jai Narain Vyas University, Jodhpur since 2013.

Dr. Lalit Singh Jhala

M.A., NET, SET, Ph.D. in Geography from Mohan Lal Sukhadia University, Udaipur. Currently, he is working as an Assistant Professor in the Department of Geography at Jai Narain Vyas University, Jodhpur. His books, titled "Regional Disparities in Tribal Area" (single author) and "Tourism Development in Desert and Humid Zones" (co-authored), were published in 2012 & 2016 respectively. Dr. Jhala, is the recipient of the "Young Geographer Award" (2008) at the Rajasthan Geographical Association (RGA) national conference. He has also served as the Vice-President of RGA from 2020 to 2022. He has participated and presented papers in various international and national conferences, seminars and workshops; and has published 15 research papers in reputed journals. He has also supervised four Ph.D. scholars from Mohanlal Sukhadia University, Udaipur and JNV University, Jodhpur, respectively.

Preface

Climate change has become an agenda of key concern and requires our utmost attention. There are several factors which collectively attribute to climate change but anthropogenic activities since the early 1700s, could be considered the major cause of it. These anthropogenic activities not only degrade the quality of the water, air and soil around it, but are also responsible for several adverse health effects on animals and humans. Recent accelerated climate change has exacerbated existing environmental problems around the globe that are caused by the combination of changes in land use, increasing pollution and declining biodiversity. Climate change can be said to be a threat multiplier. It intensifies existing threats, aggravating complications for the environment, economy and thus, the entire society. The recent global warming is already producing negative influences on natural and human systems, seriously impeding progress toward some sustainable development goals (SDGs). Sustainable development is development that meets the needs of the existing generation without compromising with the capabilities of the future generations to meet their own needs. Climate change causes hindrance in the sustainable development of the society which not only affects mankind but all the species existing in an ecosystem.

This bilingual book emphasises on the several issues regarding climate change and how these issues are interlinked with sustainable development. The 20 chapters of this book revolve around how plants and animals are affected by climate change and how they can be used as indicators of climate change, how the agriculture sector is affected by it and what policies could be brought into account to stop the climate change and lead to betterment of all via working on sustainable development goals.

We would like to thank all the authors for coming forward and presenting their ideas which helped us in moulding this book. Their efforts would help the present and future generations in understanding the importance of this topic and would open gateways of new and better research.

Foreword

Earth, life and climate have always changed and climate change itself may have been crucial for the evolution of human being. The climate system is a complex interactive system consisting of the atmosphere, hydrosphere, lithosphere, cryosphere and outer space. Climate change is a global challenge with diverse implication at the national and regional levels, through impacts on various sectors such as agriculture, water resources, forestry and biodiversity, human health, energy and infrastructure. The scientific studies indicate that climate change is inevitable. The climate has transformed in the past, is varying in the present and is bound to change in the future. Today we are erroneously worried about the global warming and the impacts it is likely to bring. Contrary to it, some scientists forecast that 'global cooling' would be more disastrous in future.

The scientists are debating on the causes of climate change. The natural scientists believe that climate changes are due to several natural forces like changes in the obliquity of earth's axis, its rotational speed, solar variability or sunspot and volcanic activities. On the contrary, some scientists who believe in global warming say that increase in the emission of green house gases after industrial revolution has been mainly responsible for global warming and climate changes. It is beyond doubt that since 1850 A.D. the temperature is rising at such a rate that it was never experienced during last 800,000 years during geological past. The 'pro-warming lobby' advocates that the earth's warming occur not only in response to external forcing but also due to release of GHG's in the atmosphere by human beings especially the burning fossil fuels.

This book **"Climate Change and Sustainable Development"** presents a systematic work on the issues of climate change. The backdrop ranges from biology, agriculture, renewable energy to human health. All of these are very important aspects of human life as impacted by the rapid change in the climate of the earth. The book offers a wide variety of topics ranging from the global scenario of climate change, the bio monitoring properties of a plant that can be symptomatic of climate change and its impacts, the issue of solid waste management, the problems of agricultural pollution, the scenario of potential and challenges of biomass energy. The wider academic and geographical area of the problems discussed in the various chapters ensures that the book is wide in its scope, methods, approaches, spatial coverage and variety of problems faced.

I take immense pleasure in congratulating all the editors, as well as, the contributing authors of this book. The editors **Dr. Om Prakash, Dr. Gaurav Kumar Jain, Mr. Govind Singh and Dr. Lalit Singh Jhala** have, through persistent hard work and academic assiduity produced a well-balanced piece of literature that is varied in its approach and perspectives.

Hence, my compliments for their ardor and zeal.

Prof. H. S. Sharma
Formerly Professor and Head Department of Geography
University of Rajasthan, Jaipur

Climate Change, Human Health and Sustainable Development: The Interlinked Trinity

Girima Nagda[1*], Chirmaie Nagda[2], Devendra Singh Rathore[2], and Bhavya Singh[2]

Abstract

In modern times, climate change is one of the greatest challenges we are facing. Besides natural phenomenon, a major chunk of climatic changes can be attributed to anthropogenic activities which have subsequently resulted in myriad devastating effects. Every aspect of climate change has negative impacts which thus break the well knitted chain of ecology of the well-balanced ecosystem of the earth. Human beings as an integral part of the ecosystem are also susceptible to the dreaded physical, biological and socio-economic effects of climate change. The very existence of human life and livelihood is affected by climate change. There are innumerable evidences which have shown that human activities are responsible for changing the climate and this change will produce some major impacts on health, both on national and global level. These climate changes and health regarding issues move beyond national borders and the impact of health hazards related to these changes affects several people as well as communities to a large extent. There are unprecedented and immense risks of climate change and environmental degradation on human population. Thus, the viscous circle of human influences on climate resulting in climate change and affecting human health and development needs to be checked for better environment to live in and sought for more eco-friendly development "sustainable development". It is necessary to understand the intricate linkage of climate change, public health and development.

Keywords: Climate change, human health, sustainable development, infectious diseases

Introduction

Climate change along with environmental degradation is amongst the biggest challenges being faced by the world today. Rise in temperature, growing intensity and incidences of extreme weather events, the destruction of forests, wildfires, the risk of extinction of a million species, spread of infectious diseases, the warming up of oceans and the disruption of ecosystem services which sustain life on this planet are amongst the major threats and challenges faced today. Events like frequent droughts, floods,

[1] Department of Zoology, [2]Department of Environmental Sciences, University College of Science, Mohanlal Sukhadia University, Udaipur, Rajasthan

* Corresponding author

hurricanes and cyclones, forest fires like the recent one in Australian region leading to massive destruction of wild animals, resurgence of diseases etc. have presented a glimpse of devastation that can be caused by climate change and environmental degradation.

Changing climate is not a new phenomenon. Over the course of evolution, the Earth's climate has undergone a continuous change. The present scenario of climate change is quite different from the traditional one as the latter makes the earth as a whole either hotter or colder. Systematic global warming is believed to be one of the major causes of climate change today. This has made the climate much more erratic making the Earth hotter and drier at some places and cooler and wetter at others, thus breaking its constancy. In a nutshell, climate change means that drastic changes will be seen in the weather conditions in the near future.

To a much greater extent anthropogenic activities have brought about the major climatic changes and subsequently it results in myriad effects on human health and development. Current trends of climate change are alarming both in terms of environment loss and human damage as impairment of livelihood, income and damage to the properties by extreme events is faced by millions of people around the world. Furthermore, as climate change negatively affects agriculture, it leads to undernourishment and deteriorates the economic conditions of the people especially in areas where it is the mainstay.

As climate change has a global effect it should be given due emphasis. Thus, it is important to promote a better understanding about climate change and create awareness of its impacts and influence on the well-being of humans, ecosystems and the development, so that the significant challenges it poses can be dealt with easily.

How climate change affects human health which in turn hampers the sustainable development approach is being discussed here.

Climate Change : Current Scenario

As per the World Meteorological Organization (WMO) the global mean temperature for 2019 was around 1.1 ± 0.1 °C above the 1850–1900 baseline, used as an approximation of preindustrial levels. The year 2019 is likely to be the second warmest on record (WMO, 2019). The Intergovernmental Panel on Climate Change (IPCC) has issued an extensive warning, stating that the Earth will face catastrophic consequences if the current trends of rising global temperatures are not reversed immediately. The report also states that an increase of 1.5°C in Earth's temperatures will affect the population disproportionately, especially the vulnerable and disadvantaged ones, by causing rise in food prices, food insecurity, unemployment, adverse impacts on health, and displacement of population (Awasthi, 2018).

Earlier report of IPCC states that by 2100, the global mean sea level rise will be around 10cm higher for a rise of 2°C as compared to 1.5°C thus, up to 10 million more people will be affected by the risk of rising seas. Similarly, in context of heat waves, a rise of 1.5°C, would expose 14% of the population to heat wave every five years and it will increase to 37% of the population at 2°C. Figure 1 shows that how the increase in temperature would affect different sectors like species, coral reefs, crops and floods.

It is suggestive from the figure that if the rise in temperature is kept below 1.5°C the Earth would have far better survival options than above it as every bit of rise will make a huge difference (McGrath**,** 2018).

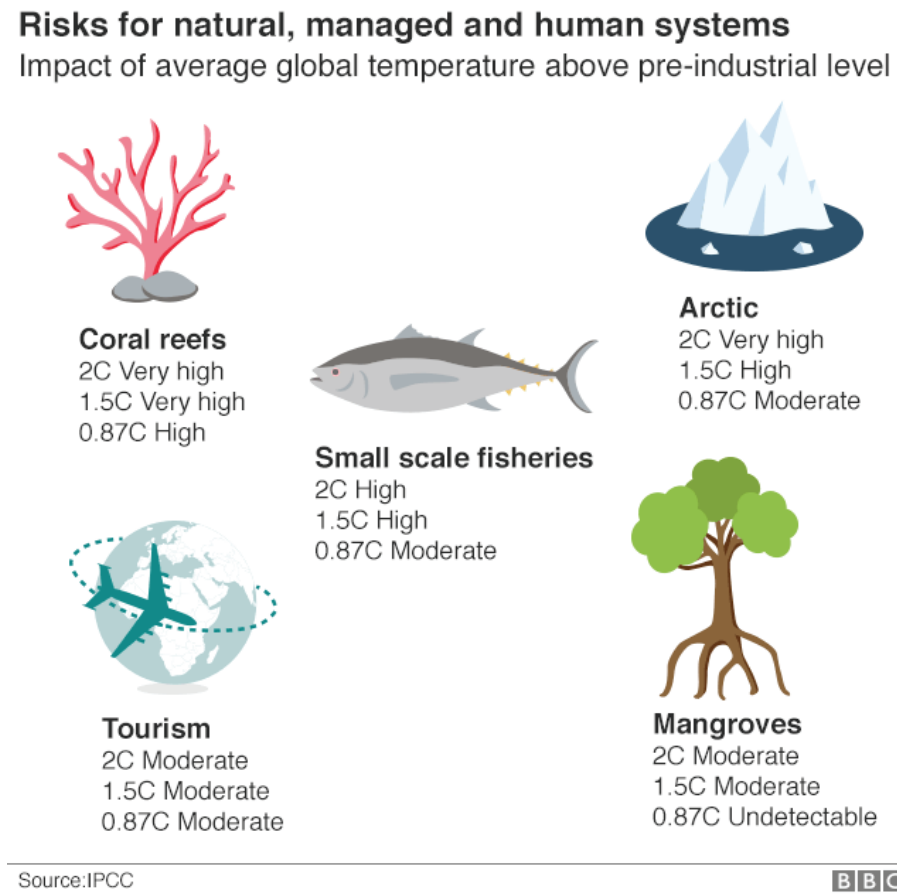

Figure 1: Impact of average global temperature rise above the pre-industrial level (Source: McGrath, 2018)

India is most significantly affected by climate change due to its large population, inequality and poverty. The impact of destabilization on India could be devastating. A report by Germanwatch, an environmental think tank, has ranked India as the fifth-most vulnerable country in terms of extreme weather events. It is believed that the current level of efforts to slow down global warming in India will result in a rise of 1-2° C in average temperatures by 2050. Thus, India is facing a dual pressure to mitigate climate change by controlling its emission growth and simultaneously needs to adapt to increased water scarcity, floods, droughts, cyclones and other natural disasters. In spite of a fairly good disaster management system, it requires more resources to develop further and is in need to set ambitious targets on renewable energy (Goswami, 2020).

A warmer Earth certainly must be avoided because of its adverse implications on ecosystems, water resources, agriculture, biodiversity, human health, economic

growth and development. Unplanned development has led to emission of greenhouse gases over decades leading to climate change. As a result, development itself suffers, because lots of resources get wasted to cope up with adversities of climate change which otherwise would have added to better health, education, and better socio-economic status of people.

Climate Change and Human Health

Human health is influenced by the climate. The environment and socioeconomic systems vital to human health and development, are sensitive to the rate and magnitude of climate change (IPCC 1996). Climate variability and climate change threatens human health and well-being in numerous ways especially by affecting the environment that provides with clean air, food, water, shelter, and security.

Climate change has both direct and indirect impact on human health. The direct impacts are due to extreme weather conditions, air pollution, heat waves etc., which can cause injuries, thermal stress, death etc. The indirect impact on human health can be either ecologically or socially mediated which can cause infectious diseases, under-nutrition, mental stress etc.

Following 11 human health issues occurring as a result of climate change have been reported (IWGCCH 2010):

1. Weather-related diseases and mortality
2. Vector-borne and zoonotic diseases
3. Water-borne diseases
4. Food-borne diseases and nutrition
5. Heat-related morbidity and mortality
6. Human developmental effects
7. Mental health and stress-related disorders
8. Asthma, respiratory allergies, and airway diseases
9. Neurological diseases and disorders
10. Cardiovascular disease and stroke
11. Cancer

Climate vulnerability includes three different properties of the human community: exposure, susceptibility to harm and the capacity of adapting to such harm (IPCC 2014). All these three properties are time dependent and are site and system specific (IPCC 2014; NRC 2012; USGCRP 2016). Thus, climate change alters the natural environment and affects the health of people by causing malnutrition, various infectious and zoonotic diseases like vector borne diseases, food & water borne diseases, diseases associated with air pollutants & aero-allergens, mental health and stress related disorders, increased respiratory and cardiovascular disease, injuries and premature deaths related to extreme weather events. (Figure 2). It is suspected that the risk to health of people by these diseases will increase significantly in coming decades (Ruhil 2016; Confalonieri et al., 2007). Figure 2. Gives an account of the impact of climate change on human health.

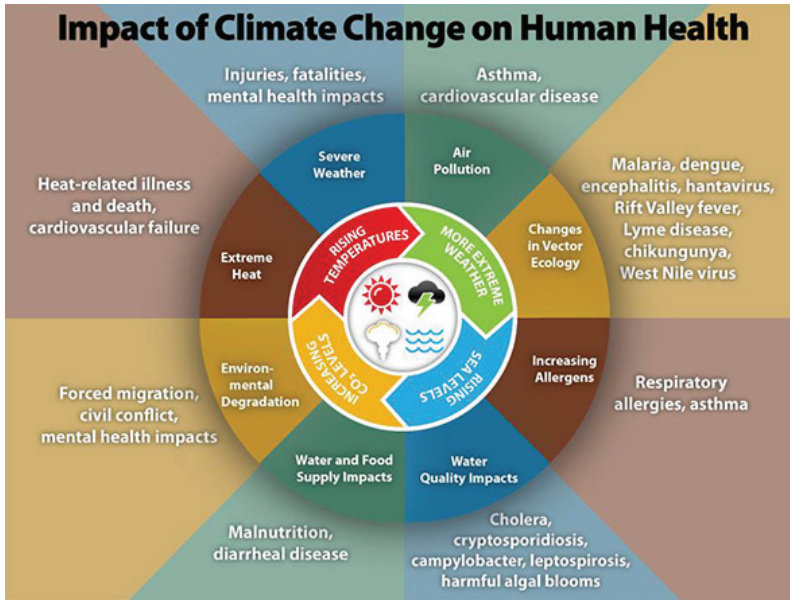

Figure 2: The impact of climate change on human health (Source: CDC, 2019 a)

Zoonotic and infectious diseases are highly sensitive to climate change. Temperature, precipitation and humidity play an important role in reproduction & survival of vectors & infectious agents. Dynamics of vector-borne diseases are influenced by multiple factors like environmental (vegetation, climate, hydrology); biological (the life cycles of insects that are vectors for infectious agents); sociodemographic (migrations and population density); and medico-social (the immunological conditions of the population; the effectiveness of local health systems, etc.), which potentialize their effects on human health (OPAS 2008). Climate change results in abnormal patterns of precipitation, humidity & temperatures, which results in mosquito breeding sites, increased survival & development of mosquitoes. Thus, prevalence of malaria and dengue has increased over recent years (WHO, 2011; Kleef and Hales, 2010). Conditions favorable to outbreaks of infectious diseases are created by the changing weather events. The incidence of mosquito-borne diseases, such as malaria, dengue, and viral encephalitis, are most sensitive to climate (Houghton, 1997). Climate change directly affects disease transmission by shifting the vector's geographic range, increasing the reproductive and biting rates and shortening the pathogen incubation period. Climate change also causes extensive spread of pests and diseases. Figure 3 shows how the burden of zoonotic diseases increases with the climate change

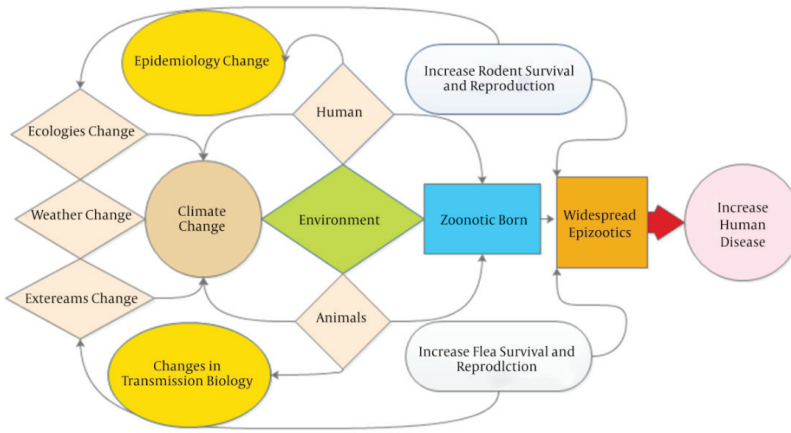

Figure 3: Concept of climate change and increased burden of zoonotic diseases (Source: Esmaeilnejad et al., 2018)

Climate change mediated increase in surface temperature of sea and sea level rise leads to higher incidence of waterborne infectious diseases like cholera and toxin-related illnesses such as shellfish poisoning. Figure 4 shows how diverse environmental changes affect the occurrence of various infectious diseases in humans.

Environmental changes	Example diseases	Pathway of effect
Dams, canals, irrigation	Schistosomiasis	▲ Snail host habitat, human contact
	Malaria	▲ Breeding sites for mosquitoes
	Helminthiasies	▲ Larval contact due to moist soil
	River blindness	▼ Blackfly breeding, ▼ disease
Agricultural intensification	Malaria	Crop insecticides and ▲ vector resistance
	Venezuelan haemorraghic fever	▲ rodent abundance, contact
Urbanization, urban crowding	Cholera	▼ sanitation, hygiene; ▲ water contamination
	Dengue	Water-collecting trash, ▲ *Aedes aegypti* mosquito breeding sites
	Cutaneous leishmaniasis	▲ proximity, sandfly vectors
Deforestation and new habitation	Malaria	▲ Breeding sites and vectors, immigration of susceptible people
	Oropouche	▲ contact, breeding of vectors
	Visceral leishmaniasis	▲ contact with sandfly vectors
Reforestation	Lyme disease	▲ tick hosts, outdoor exposure
Ocean warming	Red tide	▲ Toxic algal blooms
Elevated precipitation	Rift valley fever	▲ Pools for mosquito breeding
	Hantavirus pulmonary syndrome	▲ Rodent food, habitat, abundance

▲ increase ▼ reduction

Figure 4: Diverse environmental change and occurrence of various infectious diseases in humans (Source: Patz et al., 2000)

Food and water borne diseases are a major public health issue. Disease transmission is known to be affected by air and water temperatures, precipitation patterns, extreme rainfall events, and seasonal variations. Diseases like salmonellosis and campylobacteriosis, diarrhea occur more frequently with high temperature and unusual precipitation. As a result of climate change, disasters have become more frequent; such as hurricanes, typhoons, earthquakes, tsunamis and floods. During disasters epidemic outbreaks occur, particularly of cholera and other diarrhoeal diseases (UNICEF & WHO, 2012).

Meningococcal meningitis is another seasonal infectious disease favoured by dry, hot and dusty climate. Hunger, draught, extreme climate events, and regional conflicts also are a few factors increasing the incidence and severity of diseases, as well as contributing to other adverse impacts on health.

High temperature itself is a threat to human health particularly for elderly, chronically ill and children. It is projected that by 2050s, heat events will be very frequent (IPCC, 2012). Excessive exposure to UV radiations of sun results in premature ageing of skin and more severe outcomes like skin cancer.(Ferlay et al., 2008).

Air pollution is also directly related to morbidity and mortality, particularly exposure to unsafe levels of fine particulate matter has severe consequences to health (Ruhil, 2016). According to WHO, due to climate change, seasons of pollens start earlier and last longer, leading to more cases of asthma associated with pollen allergens. The sources of indoor air pollution include inefficient use of solid fuels for cooking (WHO, 2009) and tobacco smoke (Lin et al., 2007). Wild fires and forest fires have become very frequent. Emissions from fires contain gas and particle pollutant which has adverse health outcomes for humans and animals. Health impacts of climate change are felt globally but these health impacts are more severely felt by poor and vulnerable. Thus, poverty is both a catalyst and consequence of climate change & poor health.

Mental illness is a major cause of suffering in the advancing world today, and extreme weather events affect mental health in numerous ways. As a result of disasters, mental health problems like high levels of anxiety and post-traumatic stress disorder increase, both among people with no history of mental illness, and those at risk, a phenomenon known as "common reactions to abnormal events." Climate change like extreme weather, rising temperatures are suggestive of potential impacts on depression and other mental illnesses. Some mental illness patients like those suffering from schizophrenia are at risk during hot weather because their medications may interfere with temperature regulation or even directly cause hyperthermia (CDC, 2019b).

Global environmental changes, such as bioaccumulation of chemicals in air, water and soil, global warming, species extinction caused by destruction of natural habitats leading to reduction of genetic resources, etc. cumulatively affect the human health directly or indirectly. Reproductive problems; weakening of the immune system; behavioral anomalies; thyroid malfunction, hormonal imbalances; tumors and cancer; and congenital malformations are some of the direct effects of global changes on human health. The indirect effects are often hard to quantify because of the complex involvement of ecological mechanisms and social processes (Confalonieri et al. 2002).

Climate change is known to affect human health in two possible ways: firstly, by increasing the severity and the occurrence rate of health issues which are already affected by climatic factors and secondly by generating unforeseen health problems (USGCRP 2016).

Sustainable Development and Climate Change

Sustainable development is a development pattern which involves judicious use of resources. It aims to protect and preserve the environment while fulfilling human needs effectively in the present as well as in the indefinite future (McKeever and James, 2009). According to Robert Repetto, "Sustainable development is a developmental strategy that increases long-term wealth and human and environmental well-being by managing all the natural resources, human resources, as well as financial and physical assets. It rejects policies and practices that support current living standards at the cost of depleting the existing resources that leaves future generations with poorer prospects and greater risks than our own" (Repetto, 1986). Sustainable development implies economic growth as well as the protection of environmental quality, each reinforcing the other. It includes adoption of green technologies in all fields, which are market-driven solutions for reducing harmful impact of industries on environment (Reddy, 2010). It denies economic and social development at the cost of environmental degradation and it implies that development should not lead to the scarcity of natural resources.

The guiding rule of sustainable development is to care for the Earth. Humanity must take only that much from nature which can be replenished. This means adopting lifestyles and development paths that respect and work within nature's limits. It can be done without rejecting the many benefits that modern technology has brought, provided that technology also works within those limits"(IUCN, 1991).

Sincere concerns for environment came into existence for the first time in a global conference on the "environment and development" in Stockholm in 1972 where the challenges of economic growth towards environmental sustainability were addressed. Later, it became a regular practice and sustainable development plans were formulated in Agenda 21, Earth Summit 1992, Kyoto protocol 1997, Johannesburg summit2002, millennium development goals and now sustainable development goals (Blewitt, 2015; Elliot, 2006). At the Rio +20 Summit in June 2012 Sustainable Development Goals (SDGs) were adopted (Sachs, 2012) amongst which SDG13 particularly focuses on climate issues and climate action which need to be addressed in an interdisciplinary and holistic way.

Development is a time-consuming process but a few moments of disastrous effects of climate change could undo all the development efforts and poor countries are particularly vulnerable to the destructive effects of climate change (Thomas and Twyman, 2005; IPCC, 2007). Climate change increases shortages of potable water, sanitation and health services (Bierbaum and Fay, 2010) and also threatens food security due to direct impact on agriculture & crop yield (DFID, 2005) thus in turn hampering development.

In most of the developing countries, agriculture is dependent on rain water for irrigation. Decreasing precipitation over the years has increased the burden on

fresh water supplies. In addition, increasing environmental exploitation through processes like overgrazing, deforestation, desertification and mineral extraction has led to degradation of a large portion (about 40%) of land globally (Klugman, 2011). Moreover, poor and underdeveloped countries have limited resources to cope with climate change and its destructive effects (Thomas and Twyman, 2005; IPCC, 2007). Such episodes of extreme climate change events lead to epidemic outbreaks and thus loss of productivity (WHO, 2005). Resources which could be better utilized for development of a country are wasted in coping with disasters and the effects of climate change. The world is already facing the devastating effects of climate change; thus, cumulative efforts to mitigate harmful consequences of climate change should come from all spheres of human development.

Link Between Climate Change, Human Health and Sustainable Development

Environment and human beings are interdependent. At one hand human beings are increasingly altering the environment and on the other hand climate change is adversely affecting health of people (Lang and Raynor, 2012). Furthermore, environment and development are inseparable because the "environment" is where we live; and "development" is what we all do in attempting to improve our lot within that abode (WCED, 1987). Thus, climate change is a ubiquitous challenge for the world.

The environmental impacts on human health are enormous. The links between people, nature and economies are inescapable when looking at environmental security and environmental risks as they relate to human health and security. Aspirations for security and development therefore must be directed towards efforts to protect individuals from environmental threats. They must also be based on practical steps to seize upon the opportunities presented by the environment, in recognition of its inherent value, and its deep connections to human beings, societies and economies (Khagram et al., 2003). Sustainability science focuses on linking the human imprint on the biosphere to the co-evolving human-environment condition, as it pertains to a transition towards sustainability.

Adverse climatic condition affects human life and livelihood badly and in turn threat to human security. Now-a-days human security is defined through the vocabulary of development. Better livelihood, employment, health facilities, education, etc. are considered to be new milestones of development as well as human security. Procuring these determinants however triggers serious environmental degradation and in turn climate change.

Paradoxically, development causes climate change which in turn slows down the former. Thus, it appears to be a vicious circle. Development ensures human health and security, but it also causes climate change which ultimately threatens human health. Therefore, a proper balance is needed to bring harmony among these determiners (Parvizian et al., 2011).

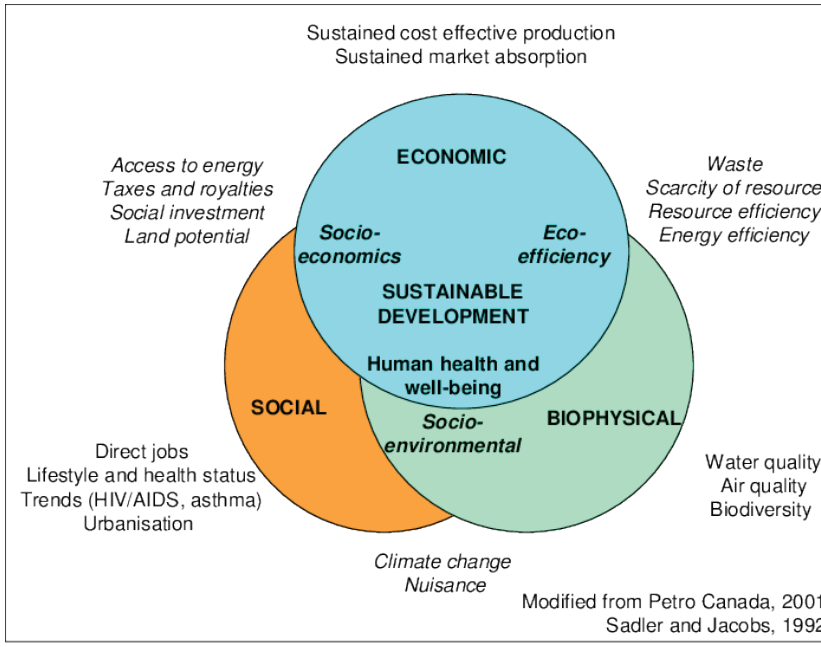

Figure 5: Three pillars of Sustainable development and their interaction (Source: Boer and O'Beirne, 2005)

Figure 5 represents:

- The 3 pillars of sustainable development i.e., economic, social and biophysical,
- Human health and well-being as central concern of sustainable development,
- Interrelationship and interaction between the pillars of sustainable development (socioenvironmental, eco-efficiency, socio-economic),

Human health is central to the three dimensions of sustainable development. Health is a beneficiary of and a contributor to development. Sustainable development focuses on a balanced relationship between anthropogenic activities and the environment, so that the benefits of the future generations are not hampered (ECO, 1999). Thus, human health and welfare are the principal consideration of environmental management and sustainable development.

Human health, as a "sustainable state" (King, 1990), requires continuous support of a rich and well-balanced ecology and protective environment. Although the socioeconomic changes over the past few decades, have improved human health but as a counter effect of this, global environmental conditions have deteriorated and affected the human health (WHO, 1995). Anthropogenically induced climatic changes have compromised the sustainability of human development, by threatening the ecological support systems on which human life depends (McMichael, 1993) and affecting the human health and well-being.

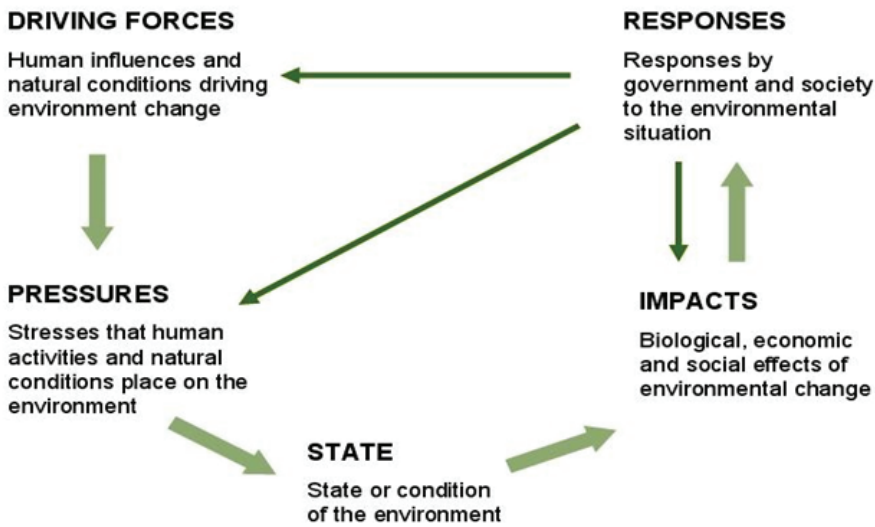

Figure 6: DPSIR framework related to interaction of human and climate

Figure 6 shows the DPSIR (Driver, Pressure, State, Impact Response) framework indicating that human influences are the main driving forces and pressures which bring about the state of climate change which in turn has biological, social and economic impact affecting the overall human health and growth to reduce these impacts favorable responses like sustainable development should be taken into account. Thus, climate change, human health and sustainable development are intricately linked.

'Health' and 'sustainable development' are complex interlinked entities. Good health usually assists development, and development often results in improved health. Equally important is the fact that our attitude towards the environment, lifestyle and consumption patterns need to be in consonance with the sustainability of the development process. Thus, human health and quality of life depends on the quality of the environment we live in (Leff, 2004).

Specific Actions to be taken to Combat Climate Change

Climate change has deep socio-economic impacts. It has been reported that unchecked climate change can result in 2.5-4.5 % decrease in GDP. To meet the challenges of climate change and environmental degradation and to achieve the 2030 Sustainable Development Goals a transformation of the economy is required. A switch from use of fossil fuels to renewable sources of energy, from traditional agriculture practices to organic farming, judicious use of our natural resources, adopting the concept of green buildings etc., are a few well known measures which can help us reduce the increasing pressure of population on our limited resources.

One of the major worldwide impacts of climate change is its effect on public health. Public health officials need to look into the matter and act accordingly to improve the overall health status of the population.

A new concept called as Building Resilience Against Climate Effects (BRACE) framework if taken into account will allow health officials to develop effective

strategies and programs to combat the health effects of climate change (Marinucci et al., 2014). BRACE is a five-step process which helps in the public health planning and response activities by incorporating complex atmospheric data, climate projections and combining it with the epidemiologic analysis. Health officials can effectively predict and respond to various climate-induced and climate sensitive health impacts by using the BRACE concept.

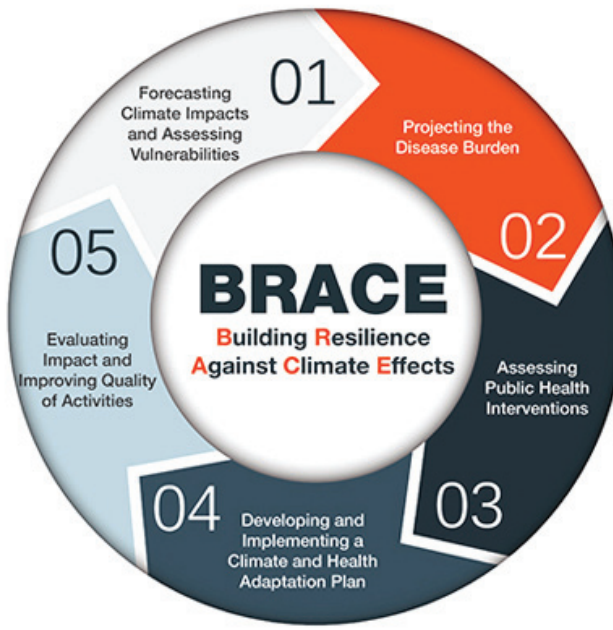

Figure 7: The BRACE framework (Source: CDC, 2019c)

The five sequential steps of the BRACE framework include:

1. Anticipating the Impacts of Climate and Assessing the Vulnerabilities: It involves identification of the scope of climate impacts, associated possible health outcomes and vulnerable populations and locations.
2. Projecting the Disease Burden: It involves estimation or quantification of the additional burden of health impacts associated with climate change.
3. Assessing Public Health Interventions: Identification of the most suitable health interventions for the identified health impacts of greatest concern.
4. Developing and Implementing Climate and Health Adaptation Plan: this step aims to develop an adaptation plan and its effective dissemination and implementation.
5. Evaluating the impact and improving the Quality of Activities : this step involves evaluation of the entire process and also determines the value of information attained and activities undertaken.

As environment and health are interdependent and inseparable, they should be priorities to development and be given precedence in the everyday management of government policies (WHO 1991).

Conclusion

As already known that climate change has multiple effects on human community which includes human health, security and overall well-being which in turn is intricately linked to the socio economic development we should work in unison towards protecting our environment. Effective environmental management and sustainable development is principally about placing humans and their needs at the forefront. For the effectiveness of public policies participation from industrial sector, public health sector, NGOs, local communities is crucial. Development should be environmentally, socially and economically sustainable. A recent example of effective replenishment of the environment comes from the COVID-19 pandemic which has resulted in a world over lockdown. It has been found that as a consequence of massive lockdown the pollution levels are lowered and the air quality has improved, the water resources are replenished and clean. Thus, public involvement and sensitivity towards environment plays a major role.

It's time to bring in more effective climate-related governance and climate change management. A shift from a fossil fuel-based energy system to a more efficient and renewable energy system, judicious use of resources and the adoption of 3Rs i.e., reduce, reuse and recycle should be brought into practice. There is a dire need to support the global efforts toward handling the causes and the many impacts of a changing climate on both human health and sustainable development.

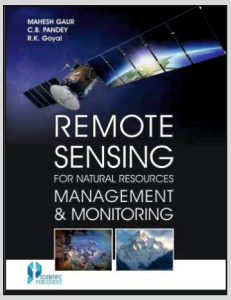
Climate Change and Sustainable Development

Om Prakash
Gaurav Kumar Jain
Govind Singh
Lalit Singh Jhala



Climate change has become an agenda of key concern and requires our utmost attention. There are several factors which collectively attribute to climate change but anthropogenic activities since the early 1700s, could be considered the major cause. Climate change causes hindrance in the sustainable development of the society which not only affects mankind but all the species existing in an ecosystem.

This book highlights the connection between climate change and sustainable development, exploring the impacts of climate change on the environment, economy, and society. It is a result of contributions from multiple authors, aimed at raising awareness and encouraging further research on the topic.

Dr. Anil Kumar Chohadia
Dr. Narendra Nirwan
Dr. Chandresh Pareek
Dr. Gayatri

Dr. Chohadia obtained his Post-Graduation in Chemistryfrom Seth Mathuradas Binani Government PG College, Nathdwara in 2003. He has been awarded Ph.D. degree in the field of photochemistry from Mohanlal Sukhadia University, Udaipur in 2009. Apart from this, he has presented research papers in many National and International level seminars, conferences and workshops and has also been awarded the best research paper. Many of his articles have been published in Scopus, Web-science indexing and UGC-CARE Listed International and National Journals and his chapters have also been published in many edited books of National and International repute. Apart from this, he has also worked as an adjudicator in many National and International conferences.

Dr. Nirwan obtained his Post-Graduation degree in Chemistry from the Department of Chemistry, University of Rajasthan, Jaipur with a position of branch topper. He has been awarded the Ph.D. degree in "Heterocyclic Synthesis and their Biological Activity" from Maharshi Dayanand Saraswati University, Ajmer in 2020. He has published more than 30 research papers in various Scopus, Web-science indexing and UGC-CARE-Listed National and International journals. His more than 10 chapters have also been published in many edited books of National and International repute. He has participated and presented research papers in more than 80 National and International conferences. He organized a National workshop titled **"Use of Technology in the Field of Education"** in 2021 during the National Science Day celebration programme. Apart from this, he has also been an invited speaker in National conferences. His area of research is Organic Synthesis and Green Chemistry.

Dr. Pareek obtained his Post-Graduation degree in Chemistry from MaharshiDayanandSaraswati University, Ajmer with a position of University topper. He has been awarded the Ph.D. degree in "Physico-Analytical studies of some new derivatives of oxazines and thiazine series" from the MDS University, Ajmer in 2009. He has published more than 25 research papers in various Scopus, Web-science indexing and UGC-CARE-Listed National and International journals. More than 7 chapters have also been published in many edited books of National and International repute. He has participated and presented research papers in more than 20 National and International conferences including Poland and is conference chair in Belgium. Apart from this, he has also been an invited speaker in many National conferences. He was awarded as a "Master of Reiki" by USUI Shiki Ryoho and an Award of Appreciation by ECB in Poland.

Dr. Gayatri obtained her Post-Graduation degree in Political Science from the SPC Government College Ajmer. She has been awarded Ph.D. degree in Political Science from Maharshi Dayanand Saraswati University, Ajmer. She has published more than 12 research papers in various Scopus, Web-science indexing and UGC-CARE-listed National and International journals. Hermore than 8 chapters have also been published in many edited books of National and International repute. She has participated and presented research papers in more than 30 National and International conferences. She organized a National Webinar in 2020 on the topic **"Challenges before Democracy"**. Apart from this, she has also been an invited speaker in National conferences. Her area of research is Local self-Government and Environmental Issues and Solutions.

अनुक्रमणिका

1. **योग एवं यौगिक क्रियाएं: एक परिचय** 1
(Introduction to Yoga & Yogic Practices)
योग का अर्थ, परिभाषा, स्वरूप, ऐतिहासिक पृष्ठभूमि, योग की विधाएं, अष्टांग योग, राजयोग, ध्यान एवं व्यक्तित्व विकास।

2. **यौगिक पाठ्य** (Yogic Texts) 12
एक विधा के रूप में योग, यौगिक पाठ्य के वर्गीकरण, हठ योग पद्धति।

3. **योग एवं स्वास्थ्य** (Yoga & Health) 24
स्वास्थ्य का अर्थ, परिभाषा, योग एवं स्वास्थ्य में संबध, स्वास्थ्य को प्रभावित करने वाले कारक, स्वास्थ्य एवं अस्वस्थ्य का समप्रत्यय, अस्वस्थता की कसौटी एवं सकारात्मक स्वास्थ्य।

4. **स्वास्थ्य एवं खुशहाली में मनोविज्ञान की भूमिका** 37
(Role of Psychology in Health and Well-Being)
स्वास्थ्यवर्धक एवं हानिकारक जीवन शैली, प्राचीन योग साहित्य के अनुसार सकारात्मक स्वास्थ्य में योग की भूमिका।

5. **सकारात्मक मनोविज्ञान एवं स्वास्थ्य** 50
(Positive Psychology & Health)
सकारात्मक मनोविज्ञान का अर्थ, परिभाषा, स्वास्थ्य उन्नयन में सकारात्मक मनोविज्ञान की भूमिका, स्वस्थ्य जीवन के लिए यौगिक क्रियाएं।

6. **ध्यान-स्वास्थ्य उन्नत करने का उपाय** 58
(Meditation-Solution for Health Promotion)
ध्यान का अर्थ, परिभाषा, ध्यान के विभिन्न प्रकार एवं पद्धतियाँ, ध्यान के लाभ।

Scanned with CamScanner

7. **व्यक्तित्वः एक परिचय** (Personality: An Introduction) 64
व्यक्तित्व का अर्थ, परिभाषा, प्रकार, श्रेणीकरण, व्यक्तित्व को प्रभावित करने वाले कारक, व्यक्तित्व विकास की प्रक्रिया।

8. **तनाव का परिचय** (Stress: An Introduction) 86
तनाव का अर्थ, परिभाषा, तनाव के कारण, तनाव के प्रभाव, जीएएस।

9. **योग द्वारा व्यक्तित्व विकास एवं तनाव प्रबंधन** (Personality Development & Stress Management Through Yoga) 99
तनाव प्रबंधन की विधीयाँ, तनाव प्रबंधन हेतु योगासन, पद्हस्तासन, त्रिकोणासन, शशांकासन, उष्ट्रासन, अर्द्ध मत्स्येन्द्रासन, भुजांगासन, मकरासन, सर्वांगासन, मत्स्यासन, शवासन, प्राणायाम, भामरी प्राणायाम, शीतली प्राणायाम, शीर्षासन, बकासन, मयूरासन, हंसासन, व्यक्तित्व विकास हेतु आसन-सूर्य नमस्कार, ताडासन, सिंहासन, कुकुटासन, धनुरासन।

पुस्तक के बारे में

योग एंव खेल, स्वस्थ जीवन शैली की आधारशिला हैं। आपाधापी के इस दौर में जब व्यक्ति तनाव से परिपूर्ण हो जाता हैं तो मानसिक सुख एंव शांति प्राप्त करने के लिए योग एंव खेल अचूक उपाय की तरह सामनें आते हैं। दिन ब दिन बढती प्रतिस्पर्धा, व्यस्त होती दिनचर्या औऱ लगातार बदलते सामाजिक परिवेश के चलते प्राणी मात्र में मानसिक स्वास्थ्य हेतु कई चुनौतियाँ उत्पन्न हुई हैं। प्रस्तृत पुस्तक योग एंव खेल के अभ्यास द्वारा मानसिक स्वास्थ्य को उन्नत करने के उपाय सुझाती हैं। यह पुस्तक सकारात्मक मनोविज्ञान की उपयोगिता को स्पष्ट करने के साथ ही जीवनदर्शन एंव जीवन कौशल को विकसित करने के उपाय के रुप में योग और खेल की विस्तृत व्याख्या प्रस्तृत करती है। इस पुस्तक को विभिन्न विश्वविद्यालय के पाठ्यक्रमों के अनुरुप विधार्थी हितार्थ लेखनबद्द किया गया हैं। विभिन्न प्रतियोगी परिक्षाओं को ध्यान में रखते हुए पुस्तक में लघु उत्तरीय एंव निबंधात्मक प्रश्नों का भी समावेश है। ऐसे में यह पुस्तक विधार्थीयों, शिक्षाविदों एंव प्रबुद्ध पाठकों के आशानुरुप होगी।

लेखक के बारे में

डॉ. रवि कुमार शर्मा प्रदेश के पत्रकारिता जगत का जाना पहचाना नाम हैं, जो पिछले 16 वर्षों से भी अधिक समय से समाज के उत्थान के लिए इलेक्ट्रॉनिक मीडीया के क्षेत्र में अपनी सेवाएं और महत्वपूर्ण योगदान दे रहे हैं। ई.टी.वी राजस्थान, जी-न्यूज और फिलहाल फर्स्ट इंडिया न्यूज जैसे प्रतिष्ठित मीडीया घरानों में विभिन्न पदो पर रहते हुए, आपने राजस्थान के आदिवासी बाहुल्य दक्षिणांचल में प्रचलित मौताणा, मानव तस्करी, बाल श्रम और ऐसी [illegible] सामाजिक कुरीतियों से जुडे संवेदनशील मसलों को प्रमुखता से कवर करते हुए कमजो[illegible] मजबूत करने का महत्वपूर्ण कार्य किया हैं। आपने आई.सी.एस.एस.आर., नई [illegible] डॉक्टरेट की उपाधि हासिल करने के साथ ही मनोविज्ञान और पत्रकारिता एंव जनसंचार विषय में दो पीएच.डी की डिग्रीयाँ हासिल की हैं। डॉ. शर्मा नें राजस्थान विश्वविद्यालय, जयपुर से पत्रकारिता में स्नात्तकोत्तर की डिग्री प्राप्त करने के साथ ही सांइस ऑफ लिविंग, योगा एंड मेडिटेशन में भी स्नात्तकोत्तर की डिप्लोमा हैं। आपने जयनारायण विश्वविद्यालय,जोधपुर से मास कम्यूनिकेशन एंड विडियो प्रोडक्शन में स्नातक की डिग्री प्राप्त [illegible] डॉ. शर्मा के 10 से अधिक शोध पत्र राष्ट्रीय और अंतर्राष्ट्रीय स्तर के जर्नल्स में प्रकाशित हो चुके हैं। आपने अब तक दो पुस्तकों का लेखन करने के साथ ही कई राष्ट्रीय और अंतर्राष्ट्रीय स्तर की सेमिनार और कॉफ्रेंसेज में पत्र-वाचन किये हैं। आपको पत्रकारिता के क्षेत्र में उल्लेखनीय कार्य के लिए प्रदेश और राष्ट्रीय स्तर के अवार्ड के साथ ही अन्तर्राष्ट्रीय स्तर पर दुबई एक्सीलेंस अवार्ड से भी सम्मानित किया जा चुका है। आप राजस्थान सरकार के सूचना एंव जनसंपर्क विभाग द्वारा अधिस्वीकृत पत्रकार भी हैं। डॉ. शर्मा शैक्षणिक उन्नयन के कार्य हेतु सिंगापुर, श्रीलंका और दुबई की यात्रा भी कर चुके हैं।

डॉ. वर्षा शर्मा वर्तमान में मोहनलाल सुखाडिया विश्वविद्यालय, उदयपुर के मनोविज्ञान विभाग में असिस्टेंट प्रोफेसर के पद पर कार्यरत है और जानी मानी क्लिनीकल साइकोलोजिस्ट हैं। डॉ. शर्मा ने सुखाडिया विश्वविद्यालय से 2009 में एम. ए. की डिग्री प्राप्त की और विश्वविधालय गोल्ड मेडल प्राप्त किया हैं। डॉ. शर्मा ने NET, SLET, परीक्षा उत्तीर्ण करने के साथ ही यू.जी.सी से JRF औऱ SRF प्राप्त किया हैं।आपने एमबीए इन ह्यूमन रिसोर्स मैनेजमेंट की डिग्री भी हासिल की और सुखाड़िया विश्वविद्यालय से पीएचडी की उपाधि प्राप्त की हैं।डॉ.वर्षा आई.सी.एस.एस.आर, नई दिल्ली से पोस्ट डॉक्टरेट की उपाधि हासिल करने के साथ ही अब तक 2 पुस्तकों का लेखन कर चुकी है। डॉ शर्मा ने बतौर अनुसंधान अधिकारी पापुलेशन रिसर्च सेंटर जो कि मिनिस्ट्री ऑफ हेल्थ एंड फैमिली वेलफेयर नई दिल्ली की इकाई है, में अपनी सेवाएं दी है। डॉ शर्मा द्वारा वैलबिइंग इंडेक्स नामक स्टैंडर्डराइज साइक्लोजिकल टूल का निर्माण किया है, जिसे वैश्विक स्तर पर समाज विज्ञानियों द्वारा अपने शोध अनुसन्धान में प्रयोग किया जा रहा है। आपके 11 से अधिक शोध पत्रों का प्रकाशन राष्ट्रीय एवं अन्तराष्ट्रीय स्तर के जर्नल में हो चुका है। साथ ही आपने 21 से ज्यादा राष्ट्रीय एवं अंतराष्ट्रीय स्तर के सेमिनार- कॉन्फ्रेंस में शोध पत्र प्रस्तुत किये है।कई अवॉर्ड अपने नाम करने वाली डॉ. शर्मा को गार्गी सम्मान, महाराणा मेवाड़ फतेहसिंह अवार्ड , एम .के. सिंघवी अवार्ड, विश्विद्यालय गोल्ड मैडल, गुजरात एकेडमी ऑफ साइकोलॉजी से रजत पदक और विप्र फांउडेशन का राष्ट्रीय स्तर का तेजस्वनी सम्मान भी प्राप्त है।

PSYCHOTHERAPY

INTRODUCTION

In the previous chapter you have learned about the concept of Abnormality, difference between normal and abnormal and also about neurotic and psychotic behaviour and their assessment. In this chapter you will learn about meaning and definition of psychotherapies, different types of psychotherapeutic procedures as well as approaches, common mental health conditions which can be effectively treated by psychotherapies. Psychotherapies are those scientific procedures which are used by the trained psychotherapists in order to provide the professional help to the client or patient. Though Psychotherapies differ on the basis of their procedures and approaches but all are focused to enhance the level of self awareness, self competence and coping skills of the clients so that they can have better and effective adjustment in day today life. In this chapter we will discuss some of the major forms of psychotherapies.

28.1 LEARNING OBJECTIVES:

After reading this chapter you will be able to:

- ✓ Understand the basic nature and process of psychotherapy
- ✓ Understand the difference between different psychotherapies
- ✓ Learn that how psychotherapies are helpful to solve the psychological issues of everyday life
- ✓ Learn that how psychotherapies are helpful to assist different mental disorders

28.2 PSYCHOTHERAPY- MEANING/ DEFINITION, NATURE, PROCESS & GOALS

28.2.1 Meaning/ Definition

Psychotherapy is a psychological intervention based on the scientific procedures and principles of psychology, which is provided by trained psychologists, psychiatrist or mental health practitioners. It is also known as 'talk therapy'. The literal meaning of psychotherapy indicates that it is made up of two Greek words 'psyche' means soul and sprit and 'therapeia' meaning healing. The major technique used in psychotherapies is talking about the

RAMIFICATIONS OF MENTAL HEALTH

INTRODUCTION

In the previous chapter you have learned about the concept of Meditation for Health and Well Being. In this chapter you will learn about Ramifications of Mental Health in which we will discuss about concept of mental health its meaning, definition and importance as well. Mental health is always overlooked in our concerns we bother about physical health, but plight of the hour is we are not yet aware about the importance of mental health. This chapter will explain the ramifications of mental health on intellectual health, emotional health, social health, moral health and spiritual health.

23.1 LEARNING OBJECTIVES

After reading this chapter you will be able to:

- ✓ Understand the meaning and definition of mental health
- ✓ Learn about the importance of mental health
- ✓ Understand how mental health acts as an instrument for achieving the goal of overall health and happiness
- ✓ Understand the ramifications of mental health
- ✓ Learn the concept of intellectual health, emotional health, social health, moral health and spiritual health.

23.2 Mental Health – Concept, Definitions and Importance

Before we discuss about mental health it is important for us to understand about the concept of health first. What is Health? It is not only the absence of any physical ailment or disease. **According to WHO**, "Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity."

As per the definition of health it is clear that mental health is an important aspect of all over health. Mental health is nothing but a state of emotional, social and psychological wellbeing. In other words,mental health is an indicator of having good understanding about our own thoughts, emotions and actions.Let's learn some definitions of mental health-

About the authors

Dr. A. K. Goswami, retired professor and BSR faculty fellow is a known name in the field of analytical and coordination chemistry. Over a span of 33 years of his teaching and research career he had enormously contributed to his field. Starting from electrochemistry as his field of doctoral research, he moved on to spectrophotometric studies and metal complexes. Thoroughly and exhaustively working on development of analytical reagents, particularly hydroxytriazenes, for transition metal determination via spectrophotometric or complexometry, he focused on medicinally important complexes or ligands, adsorption corrosion or even theoretical drug designing of late. Prof. Goswami has more than 135 research publication in journals with high impact, 33 doctoral students and more than 7 books to his credit. The present book is his third book with De Gruyter, and he is working on more such books to his list.

Dr. P. K. Baroliya, Assistant Professor at the Mohanlal Sukhadia University, Udaipur, since 2012. His research interests include medicinal chemistry, water treatment by adsorption and catalysis. He has been part of numerous research groups, and is a well-known lecture and author of scientific papers of national and international repute.

राजस्थानी साहित्य परम्परा में श्रीकृष्ण

—डॉ. राकेश सालवी

भारतीय भाषाओं, साहित्य एवं संस्कृति में ही नहीं वरन् विदेशी भाषाओं एवं साहित्य में भी श्रीकृष्ण का विशिष्ट स्थान है। भारतीय भाषाओं में श्रीकृष्ण का चरित्र प्रबन्ध काव्यों, खण्ड काव्यों में रचा बसा है। राजस्थानी भाषा में भी कई के रचनाकारों ने श्रीकृष्ण के जीवन पर आधारित काव्य रचे। चाहे शिष्ट साहित्य हो या लोकसाहित्य सभी में श्रीकृष्ण का चरित्र एक नायक के रूप में अंकित हुआ है। श्रीमद्भागवतगीता भारतीयों के हृदय में रची बसी है। श्रीकृष्ण हैं ब्धा तो आमजन की जिव्हा पर रची बसी है। प्राचीन एवं मध्यकालीन राजस्थानी साहित्य में तो श्रीकृष्ण पर साहित्य सृजना हुई है पर आधुनिक साहित्यकार आधुनिक चिन्तन के साथ श्रीकृष्ण पर काव्य एवं गद्य में रचनाएं कर रहें हैं।

राजस्थानी साहित्य में कृष्ण भक्ति हो, राम भक्ति, शिव भक्ति या शक्ति की रचना हो। इस दृष्टि से राजस्थानी भक्ति साहित्य बहुत ही समृद्ध है। राजस्थानी साहित्य में कृष्ण से संबंधित सगुण एवं निर्गुण भक्ति का स्वरूप हमें दिखाई देता कृष्ण साहित्य में हमें रस की दृष्टि से शांत, शृंगार, वीर, वीभत्स एवं करुण रस का आस्वादन होता है। राजस्थानी साहित्य जैन शैली, चारण शैली एवं लौकिक में में श्रीकृष्ण के जीवन पर आधारित ग्रन्थ में रचे गए। ''जैन साहित्यकारों में न कृत हरिवंश-पुराण (र.का. 11वीं शताब्दी वि.), रविसागर कृत प्रद्युम्न-रास (र.का. 1207 वि.), यशकीर्ति कृत पाण्डव-पुराण (र.का. 1497 वि.), यशकीर्ति कृत द्रौपदी रास (र.का. 1693 वि.)'' जिसमें श्रीकृष्ण का चरित्रांकन किया गया है।

मीराबाई श्रीकृष्ण की भक्त परम्परा की उपासक रही हैं। मीराबाई की भाषा

बोलचाल की राजस्थानी है। मीरा के पदों में प्रेम भक्ति, मीरा की उपासना दंपति भाव की थी। इनकी कविता में भक्ति और शृंगार दोनों रूप नजर आता है।

जाओ हरि निरमाहना रे, जाणी थारी प्रीत।
तेरा कोई नहँ रोकरणहार, मगन होय मीरा चली।
ह्मारो जनम-मरण रो साथी, थाँने नहँ बिसरुँ दिन राती।
राणाजी ह्माँणै या बदनामी लागे मीठी।
ह्माँरे सिर पर साळगराम, राणाजी ह्माँरो काँई करसी।

ईसरदास का जन्म सं. 1595 में जोधपुर के भाद्रेस गाँव में हुआ था। इन्होंने राजस्थानी की डिंगल शैली में हरिरस एक उत्कृष्ट कोटि का आध्यात्मिक ग्रंथ रचा। दोहा, गाथा, मातीदाम, बिअखरी और छप्पय छंदों में रचित है।

विखो ब्रज मांझ पड़यौ बोह बार
धरै नख वार किता गिर धार
बजाड़ि तु वार किताइक वंस
किता तैं फेरां जीत्योहि कंसंप

ईसरदास कृत वि.स. 1595-1676 गुण भागवत, माधोदास कृत वि.स. 1960 भाषा दसमस्कंध, खेतसी सांदू कृत भाषा-भारथ र.का. वि.स. 1760 श्रीकृष्ण संबंधी डिंगल शैली के काव्य है। श्रीकृष्ण संबंधी पौराणिक साहित्य में सोढ़ीनाथी (अमरकोट) कृत बालचरित्र सं.1731, और कंसलीला सं.1731, भीम कवि कृत हरिलीला र.का. सं.1541 तथा श्रीमद्भागवत्, हरिवंशपुराण उल्लेखनीय रचनाएँ है। मीरां और चन्द्रसखी के भजन भी कृष्ण से संबंधित है। निम्बार्क संप्रदाय के परशुरामजी का श्रीकृष्ण चरित सं. 1677 प्रमुख रचना है।

सांखला करमसी रुणेचा रचित 'क्रिसनजी री वेलि' की हस्तलिखित प्रति सं.1635 प्राप्त हुई थी। 22 पद्यों की रचना है। जिसमें रुखमणी का नख-शिख वर्णन है।

''सीस तरुणि श्री फल सारिषउ
भाल मुगत सिंदूर भरि
नषत्र माल सोहंति कि निसि भरि
चँदन तिलिक कि चंद परि।।''

पृथ्वीराज राठौड़ बीकानेर नरेश राव कल्याणमल के पुत्र और राव जैतसी के पोते थे। राजस्थानी भाषा की डिंगल शैली के कवियों में पृथ्वीराज का स्थान बहुत ऊंचा है। इनके रचे ग्रन्थों में क्रिसन रुकमणी री वेली, दसम भागवत रा दूहा,

वसदेरावउत रादूहा भगवान श्रीकृष्ण भक्ति पर है। क्रिसन रुकमणी री वेलि में रुकमणी की बाल्यावस्था से लेकर कृष्ण के परिवार तक की कथा समाहित है। यह शान्त, शृंगार एवं वीर रस की रचना है। यह एक खंड काव्य है।

''परमेसर प्रणवि, प्रणवि सरसति, पुणि
सद-गुरु प्रणवि, त्रिण्हे तत-सार
मंगळ-रूप गाइजइ माहव्
चार सु अे - ही मंगळचार।

शान्त रस में कवि ने मंगलाचरण प्रस्तुत किया है—

आरोपित हार घणउ थ्यउ अंतर
ऊर-स्थळि कुंभ-स्थळि आज
सु-जु मोती नहि न लहइ सोभा,
रज तिणि सिरि नाखइ गज-राज।

कवि पृथ्वीराज राठौड़ ने इसमें रुकमणी के शृंगार का वर्णन किया है।

चोटियाळी कूदइ चउसठी चाचरि,
धू ढळियइ ऊकसइ धड़
अनंत अनइ सिसुपाळ अउझड़इ
झड़ मातउ माँडियउ झड़।।''

वेलि में कवि ने वीर रस के अन्तर्गत युद्ध का वर्णन किया है।

ठकुर जी रा दूहा पृथ्वीराज राठौड़ की कृष्ण भक्ति की रचना है। कृष्ण के दोहों के अंत में वसदेव राव उत आता है।

''प्रभु दे फण फण पाग, थेइ थेइ तनु करता थया।
नचायौ तै नाग, विहबल वसदेरावउत।।''

सायांजी झूला शाखा के चारण थे। इनका जन्म सं.1632 में हुआ। साँयाजी श्रीकृष्ण के भक्त थे। इनके काव्य कृष्ण भक्ति पर थे। काव्यों की भाषा राजस्थानी है डिंगल शैली की इन रचनाओं पर गुजराती भाषा का प्रभाव है क्योंकि साँयाजी काठियावाड़ी थे। रुक्मिणी-हरण और नागदमण इनकी उत्कृष्ट रचनायें हैं।

सायांजी का रुक्मिणी-हरण वीर रस का वर्णनात्मक खंड काव्य है। अकबर संबंधी प्रवाद के अनुसार पृथ्वीराज कृत क्रिसन रुखमणी री वेलि से भी रुक्मिणी हरण को श्रेष्ठ काव्य कहा गया है। रुक्मिणी हरण का आधार श्रीमद्भगवत महापुराण है। रचना में वीर रस के साथ कही-कही पर शान्त, शृंगार और वीभत्स रसों का भी वर्णन हुआ है। वैणसगाई अलंकार का निर्वाह हुआ है।

भेटतां अंबिका हुओ मन-भावीयो।
अंतरीप येडि रथ महमहण आवीयो।।
दुलहणी झालि वैसारतो देपीयो।
एवडो सेन पण चित्र आलेपीयो।।

सायांजी का नागदमण श्रीकृष्ण की बाललीला पर आधारित एक चरित्र काव्य है। श्रीकृष्ण और कालिया नाग इस आख्यान के विशिष्ट पात्र है। वीर रस प्रधान यह एक खंड काव्य है।

जदुनाथ काली समी वाथ जोड़ै,
घंणी भोम चाली चढी वात घोडै।
ऊभा गाय गोवाळ झूरंत आरै,
ळहाकार हक्कार संसार सारै।।

श्रीकृष्ण पर 'हरि लीला सोलह कला' की रचना भीम कवि ने सं. 1541 में दोहों, चौपाइयों और पदों में की।

''वृंदावन गोपी नाचेरि तेणि रंगे राचे राम।
श्राग मधूर स्वर आलवे री गाए हरी वीलाश।।''

अलूनाथ कविया का जन्म 1560 वि. के आसपास हुआ। अलूनाथ के कवित्त (षट्पदियां) राजस्थानी कवि समाज में अजोड़ गिनाये गए है। इनकी प्राप्त कविताएं मुक्तक ही है। इनकी रचनाओं में नए-नए प्रतीकों पौराणिक कथाओं का बखान है। राजस्थानी भाषा में ओज, प्रसाद गुण के साथ शान्त रस की रचना है। हर षट्पदी का स्वतंत्र आस्तित्व है।

''काराग्रहि जामेवि कणय मणि भूषण धारण
अर्द्ध निसा अस्टमी क्रस्ण भूअ और उतारण
क्रस्ण करिहिं संमिले मात जसुदा तिणि रखखय
वे कंस निरवंस हिये पित मात हरखखय
कप्पूर हलिद्रा कुम-कुमा मिलय संग गोकुल मही
निसि दिवस द्वार नंदराइ रै दधि कादव ममना वही।।''

परशुराम का रचना काल सं. 1677 के लगभग है। इन्होंने 22 ग्रन्थ और 750 फुटकर पद रचे। श्रीकृष्ण चरित, सिंगार सुदामा चरित, द्रौपदी का जोड़ा ग्रंथ राजस्थानी भाषा की पिंगल शैली की रचना है। 'बलभद्र वेलि' के रचविता सालिग 16 वीं शती के कवि थे। यह 28 छंदों की छोटी रचना है। इसमें बलभद्र और कृष्ण की अन्तिम जीवन झांकी दिखाई गई है।

''द्वारिका नयरी नीकल्या, वे बंधव इक ठाय।
त्रिखा ऊपनी कृष्णनई, बंधव पाणी पाय।।''

नरहरिदास रोहड़िया शाखा के चारण लक्खाजी के पुत्र थे। इनकी रचना अवतार चरित्र में राम के साथ कृष्णावतार, कपिलावतार, बुद्धावतार का बखान है। भाषा शैली पिंगल है। कल्याणदास रचित गुण गोविन्द में श्रीकृष्ण के साथ श्रीराम की विविध लीलाओं का सरस और भक्ति भाव के साथ बखान है। डिंगल शैली में रचित यह ग्रन्थ 197 छंदो की रचना है। कुशलधीर सोजत निवासी जैन कवि थे। इन्होंने क्रिसन रुखमणी री वेली की टीका सं.1696 में की। जो गद्य में है।

''हिव रुक्मिणी माता नउ कथा प्रसंग कहई। दक्षिण दिसिइ विदर्भ नामा देस दीपइ। तीयइ देस विषद कुंदणपुर नामइ पुर नगर अत्यन्त सर्वोत्कृष्ट पणइ शोभइ। तणि नगर विषद भीषमक एक राजा राज करइ।''

किशनगढ़ महाराज राजसिंह के पुत्र नागरीदास का जन्म सं. 1756 को हुआ। इनका मूल नाम सावंतसिंह था। कविता में नागरी, नागर, नागरिया और नागरीदास लिखा करते थे। ये संस्कृत, फारसी और ब्रजभाषा के ज्ञानी थे। इनकी कृष्ण जन्मोत्सव कवित्त, गोवर्धनधारक के कवित्त, फाग गोकुलाष्टक रचनाएँ हैं। इन्होंने वैष्णव संप्रदाय के कृष्णोपासक की भांति राधाकृष्ण शृंगार रसात्मक कविता रची।

पुष्कर क्षेत्र निवासी हित वृंदावनदास गौड़ ब्राह्मण थे। इनका जन्म सं. 1765 में हुआ। वृंदावनदास श्रीकृष्ण के भक्त थे। इन्होंने श्रीकृष्ण लीला पर छोटे बड़े कई ग्रन्थ बनाए। कृष्ण गिरि पूजन वेलि, कृष्ण गिरिपूजन मंगल, कृष्ण सुमिरन पचीसी, कृष्ण विवाह उत्कंठा, राधा जन्म उत्सव वेलि, राधा बाल विनोद आदि मुख्य ग्रन्थ हैं।

''न्याइ काम करवट व्है निकसत, पिय अरु रूप गुमानी।
वृंदावन हितरूप, कियो वस, सो कानन की रानी।।''

गवरीबाई का जन्म सं. 1815 में डूँगरपुर में हुआ। बचपन में ही ये विधवा हो गई। इन्होंने भागवत, गीता के साथ धार्मिक ग्रन्थों का अध्ययन किया। गवरीबाई को मीरा का दूसरा अवतार माना जाता है। इन्होने 610 फुटकर पद लिखे। इनकी भाषा राजस्थानी पर गुजराती और ब्रजभाषा का प्रभाव है। माखन चोरी, डाणलीला, रास लीला का मनोहारी वर्णन आपके पदों में मिलता है।

''गवरी गउ गोपाल की, चरण चारा रस च्हाय
वंकी टेंढी जो चले तो करे गोपाल सहाय
गवरी कर गोपाल सहाय ज्युं बालक के मात
कालो, घेलो बावरो, तो हुँ न छाडे तात।।''

हरिजी रो ब्यांवलो अथवा रुकमणी मंगल पदम तेली की रचना है। 17वीं शताब्दी में रचित यह विविध राग-रागिनियों में लिखा गया है। गायक मंडलियाँ रात्रि में इसे गाया करती है। जसनाथी संप्रदाय की किसनजी रो विवाहलो रचना है। जवान सिंह मेवाड़ के महाराणा भीमसिंह के पुत्र थे। जवान सिंह ने ब्रजभाषा में अनेक कवित्त, सवैया, पद बनाए जो ब्रजराज पद्यावली के नाम से विख्यात है। इनके काव्य में आत्म समर्पण, श्रृंगार और भक्ति स्पष्ट दिखाई देती है।

''उद्धव आय गए ब्रज में सुनि गोपिन के तन में सुख छायौ।
आनंद सौ उमगी सगरी चलि प्रेम भरी दधि आन बँधायौ।।
पूछति है मन मोहन की सुधि बोलता ही दृग नीर चलायौ।
देखि सनेह सखा हरि के घनश्याम वियोग कछू न सुनायौ।।''

बूंदी निवासी जीवनलाल का जन्म सं. 1870 में हुआ था। सोलह वर्ष की आयु में इन्होंने बारह हजार श्लोकों का 'कृष्ण-खंड' नामक ग्रन्थ बनाया। रचना में भक्ति और श्रृंगार की प्रधानता है। गुलाबजी बूंदी के दरबारी कवि थे। इनकी रचनाओं में ध्यान रूप सवतिका बद्ध कृष्णचरित्र, कृष्ण लीला, कृष्ण चरित्र उल्लेखनीय हैं।

जयपुर के राजा आनंदराम कछवाहा की पुत्री ब्रजदासी रानी बांकावती का जन्म वि.सं. 1760 को हुआ। इनकी रचना श्रीमद्भागवत रचना राजस्थानी में अनुवाद है, जिसमें भागवत महात्म्य के साथ राधा-कृष्ण का चरित्र वर्णन है। इनकी 'विवाह विलास रचना' में राधा-कृष्ण का वर्णन है। सूरज कँवर की रचनाएँ कृष्ण कीर्तन और कृष्ण निंद्रालीला में राधा-कृष्ण के मिलन प्रसंग, युगल लीलाओं का बखान है। जामसुता जाडेची जी प्रताप बाला की रचना प्रताप कुंअरी पद रत्नावली नामक पुस्तक मिलती है। बाघेली रणछोड़ कुंअरी कृष्ण भक्त हरजस बनाकर गाया करती थी।

बावजी चतुरसिंह जी ने श्रीमद् भगवद् गीता पर गंगाजळी टीका की रचना की। अर्जुन जब महाभारत के युद्ध से विमुख होना चाह रहा था। तब श्रीकृष्ण आत्मा की अमरता की बात कहते हुए समझाते हैं।

''नीं जन्म लेवै न मरे कदी यो
वणै नहीं तो वगड़ै कदी यो
सदा अनाशी अज अेक भांत
मारयाँ मरै यो नहिं देह साथ।''

भक्त कवयित्री मीरांबाई रचित मीरा बृहत्पदावली कृष्ण भक्ति का एक ग्रन्थ है। जिसमें मीरांबाई की कृष्ण के प्रति सगुण और निर्गुण भक्ति काव्य में दृष्टिगत होती है।

''मोर मुकुट पीताम्बर सोहे, गले बैजन्ती माला।
मीरां के प्रभु गिरधर नागर, ठाकुर बंसीवाला।।
यांकी सूरत पर बलिहारी माय।।'' काव्य में मीरां का विरह, भक्ति भाव का रूप नजर आता है।

श्री रामनाथ कविया का जन्म चोरवा का बास सीकर में सं. 1865 वि. में हुआ। इनकी द्रौपदी विनय (करुण बहत्तरी) 72 छंदों की एक व्यंग्य काव्य है। जिसमें द्रौपदी के चीरहरण के प्रसंग पर द्रौपदी द्वारा सभा में मौजूद सभी सभासदों पर व्यंग्य करते हुए श्रीकृष्ण को सहायता करने की प्रार्थना करती है। सोरठा छंद में रचित एक खंड काव्य है।

''चित में दुस्ट कुचाव, औ निलज्ज लायौ अठै।
अब गिरधर झट आव, साय करण नै साँवरा।।''

राजस्थानी भाषा का ''मानखो'' गिरधारी सिंह पड़िहार का खंड काव्य है। काव्य में गन्धर्व चित्रसेन की पान की पीक गालव ऋषि पर गिरती है। श्रीकृष्ण उसे दण्डित करने का निश्चय करते हैं। कृष्ण की बहिन और अर्जुन की पत्नी चित्रसेन की पत्नी का विलाप सुनती है। सुभद्रा श्रीकृष्ण के सामने युद्ध करने के लिए अर्जुन को तैयार कर देती है। श्रीकृष्ण और अर्जुन में भयंकर युद्ध होता है अर्जुन जब पाशुपत शस्त्र उठाता है। नारद और गालव ऋषि आकर मानवता की रक्षा के लिए युद्ध बन्द करने का अनुरोध करते है।

''ह्यारै तो हिंवड़ै में खड़कै,
एक चढै उतरै है।
धरती रो थंभो हालै है,
गिरधर जुलम करै है।।''

नारी के वीर चरित्र के साथ मानवता का संदेश देने वाला यह काव्य ऊँच कोटि का है।

आधुनिक काल के स्त्री कवियों में समान बाई का नाम उल्लेखनीय है। कृष्ण बाळ लीला रचना में भक्ति संबंधी अनूठे पद हैं। वि.सं. 1882 में सीकर जिले के नरसिंहपुरा गाँव में समान बाई का जन्म हुआ।

''यह उपमा है सब कृष्ण योग, औरन कूं लिखनूं है अजोग।
पति परमेश्वर समझैं जु तीय, उनकूं है लिखनू वाजबीय।।''

नारायण सिंह भाटी रचित 'मीरां' काव्य में मीरां के दुःख, दर्द के साथ भक्ति का रूप उजागर किया गया है।

''अरे गायाँ रा ग्वाळ
इण सिंघासण बैठ
थूं ही करण लागौ
कांई गूजरी सूं भेद
कांई मांखण मंगायाँ ही मूंडै बोलसी ?''

सत्यप्रकाश जोशी का सन् 1960 में रचित काव्य ''राधा'' काव्य में राधा के माध्यम से महाभारत के विनाशकारी युद्ध टालने की विनति दिखाई देती है।

''मन रा मीत कान्हा रै—
जग मे जे मडग्यौ घमसाण, तौ
भाई पर भाई करसी वार
आपस में लड़सी, मरसी मानखौ।
चुडला फेडैला काळ्ा ओढ,
अमर सुहागण थारी गोपिया।
कामणिया विकसी बीच बजार,
कुण तौ उघडी बैं ना नैं ढाकसी।
पिरथी पुरखा मू होसी हीण,
टाबर कहासी विना बाप रा।''

अम्बु शर्मा कृष्णायण हिंदी महाकाव्य में राजस्थानी काव्य छंदो और लोक शब्दों का समावेश कर कुल 684 पृष्टों में 95 लीलाओं को सम्मिलित किया है। कृष्ण लीला—गोपिका गीत की रचना की।

''जुगाँ जुगाँ वढ़ जाय घटै घर पाछा आयां
व गोधूळ्यै वेल जिवै मुख कृष्ण दिखायां।।''

लोक साहित्य के अन्तर्गत भक्ति भावना लोक गीतों में हर-जस के रूप में अभिव्यक्त होती है। हर-जस में कृष्ण-लीला पर आधारित गीत प्रचुर मात्रा में

उपलब्ध होते है। जो माखन चोरी, गो-चारण, नाग-दमण, चीर-हरण, रास और मथुरा गमन आदि लीला लोक में लोकानुरंजक और लोक रक्षक के रूप में लोक में व्याप्त है। लौकिक काव्यों में रतन खाती की नरसीजी रो माहेरो में नरसीजी की पुत्री नानीबाई के ससुराल में भात भरने की कथा है। मेवाड़ अंचल के गवरी लोक नृत्य-नाट्य में भी कान्ह-गुजरी नाट्य आज भी प्रस्तुत किया जाता है। लोक-भारत स्यावकरण घोड़ों (श्यामकर्ण घोड़ा) लोक गाथा में महाभारत विजय के बाद अर्जुन जब अभिमानी बन जाता है तो स्यावकरण घोडा सिर्फ श्रीकृष्ण का ही अपनी पीठ पर बैठने देता है। द्रौपदी के कहने पर घोड़ा अर्जुन को बिठाकर वायुमण्डल में से समुन्द्र में जा गिरा। फिर दानव नगरी में अर्जुन को सूली पर चढ़ाने का आदेश दिया गया। अर्जुन श्रीकृष्ण का स्मरण करने लगा। श्रीकृष्ण नीलकण्ठ पक्षी का रूप धर कर अर्जुन को बचाते हैं।

राजस्थानी साहित्य में श्रीकृष्ण से संबंधित साहित्य रचा गया है। जैन शैली, चारण शैली, संत शैली एवं लौकिक शैली के अन्तर्गत श्रीकृष्ण का चरित्र उद्घाटित हुआ है। राजस्थानी साहित्य में प्राचीन काल से लेकर आधुनिक काल में श्रीकृष्ण से संबंधित साहित्य की एक समृद्ध परम्परा रही है।

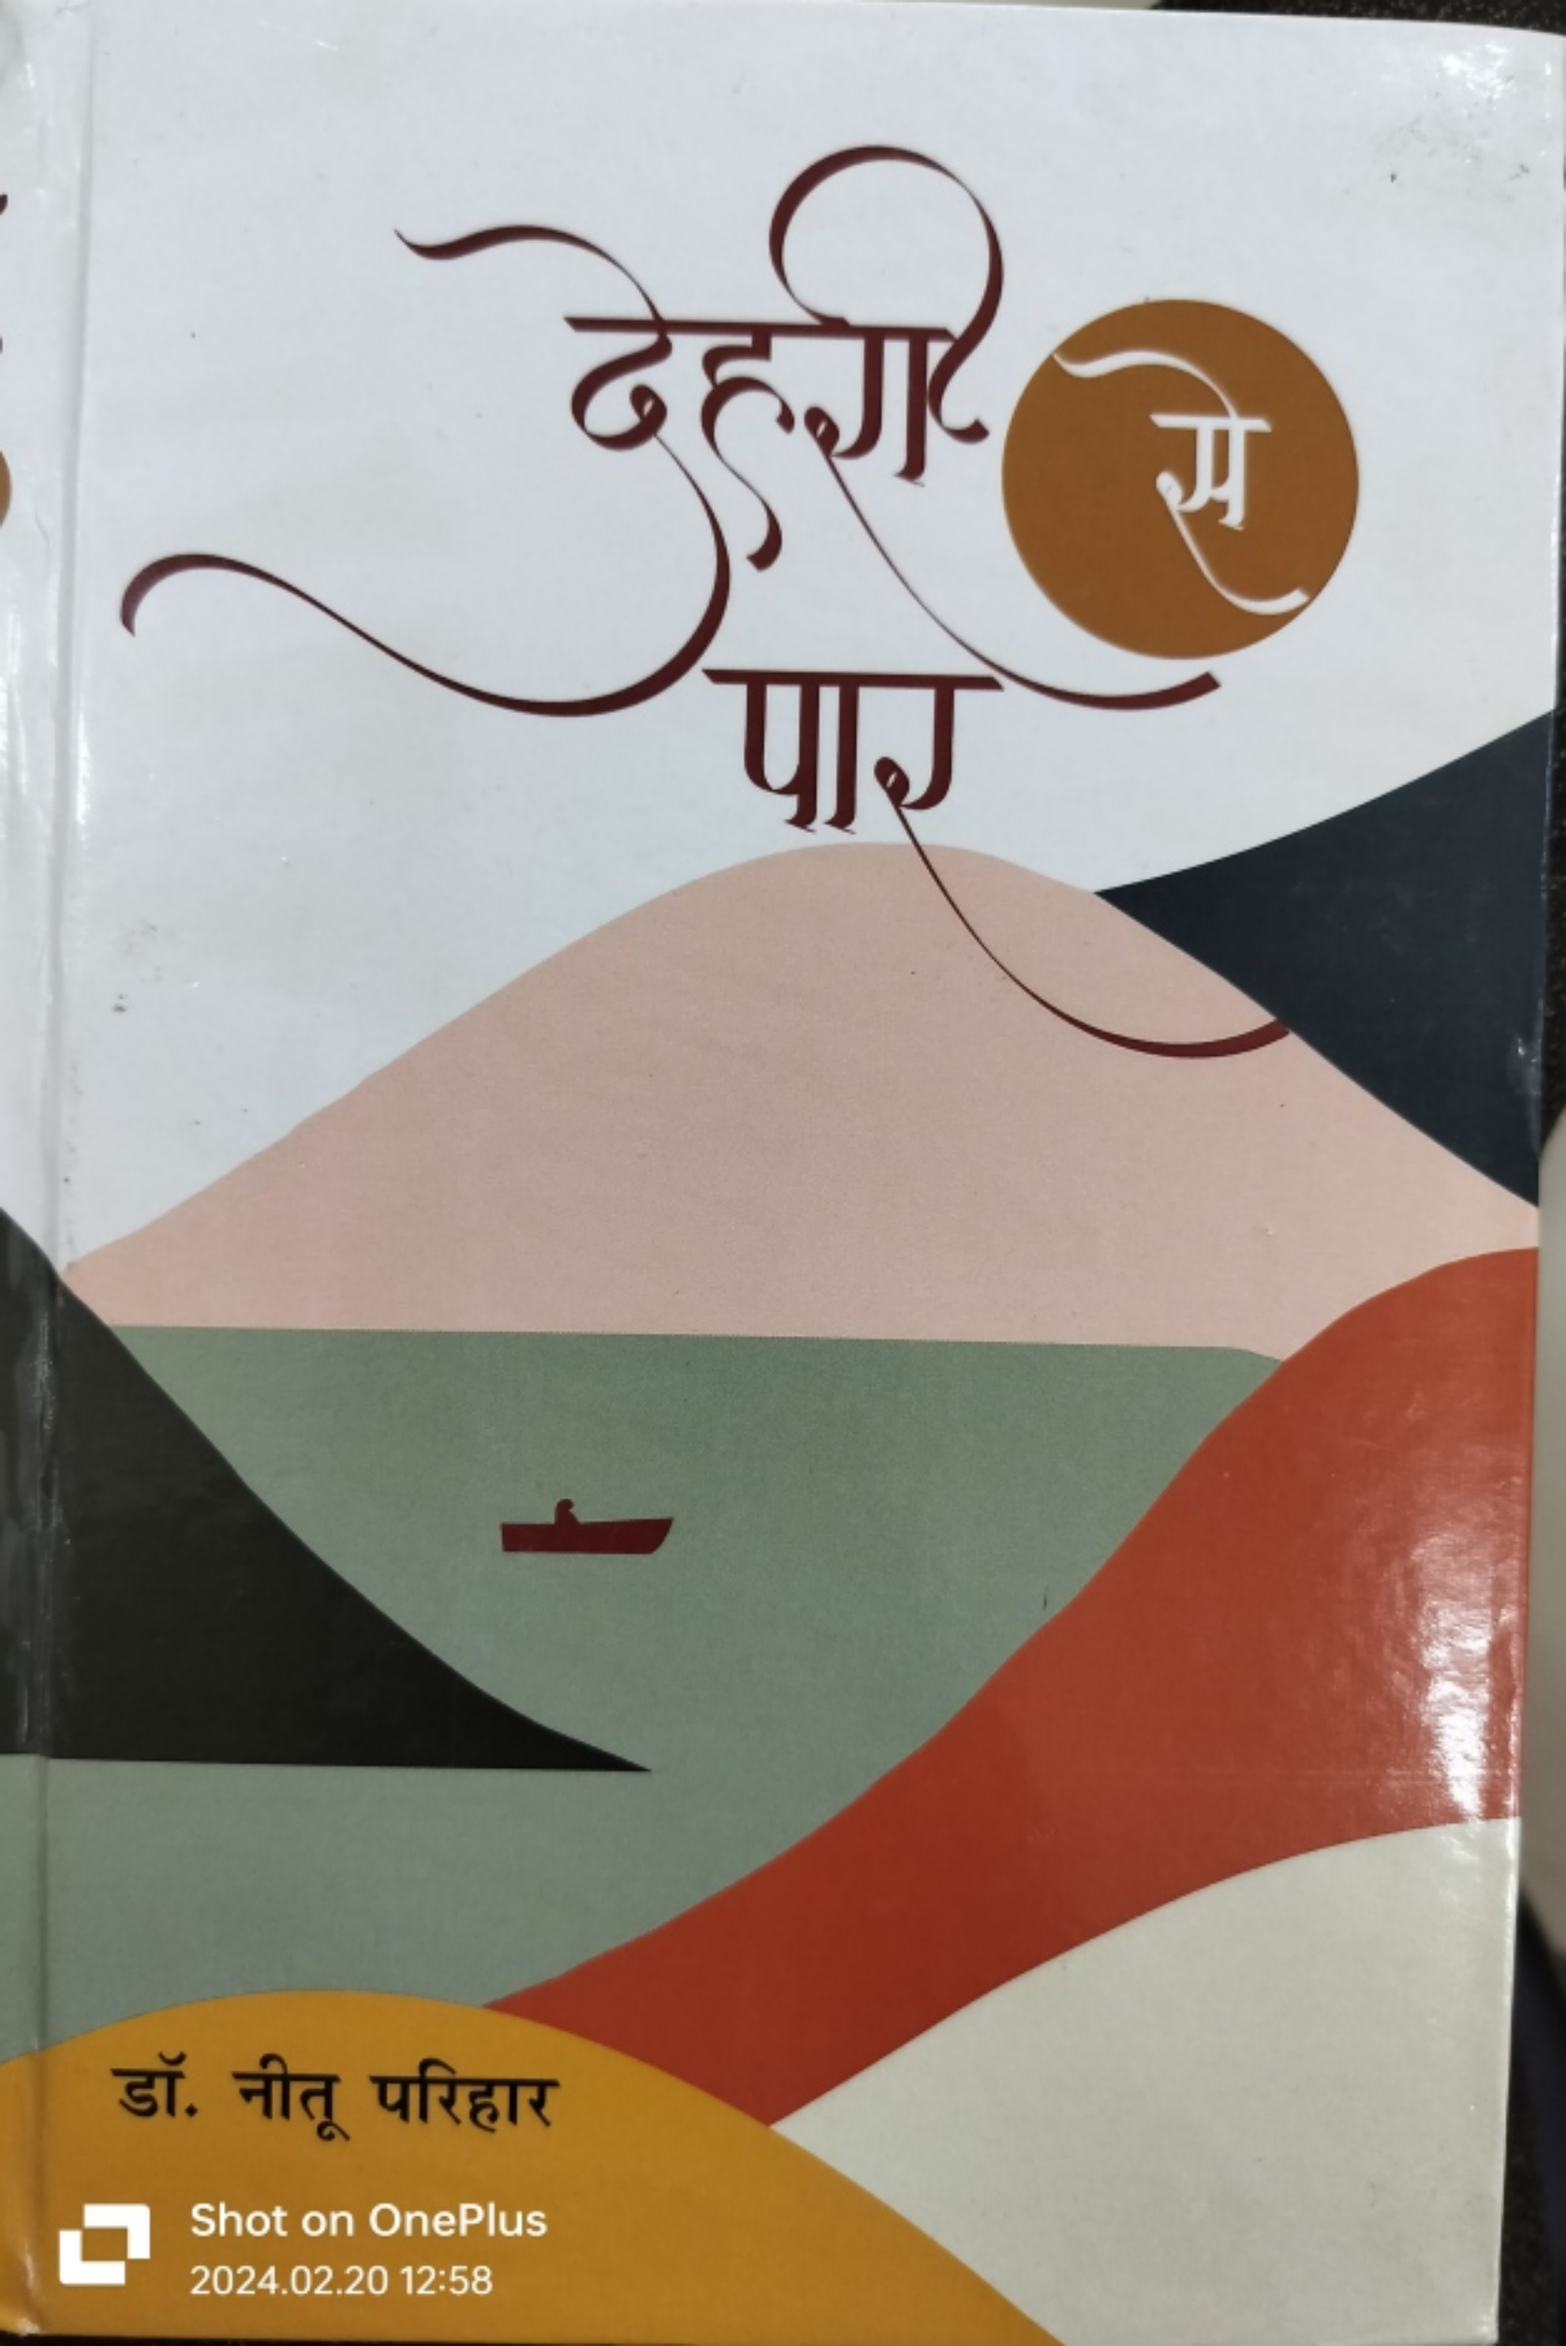
विश्वास के दीये-सी टिमटिमाती : वर्तिका नन्दा

—डॉ० नीतू परिहार



आधुनिक हिंदी कविता में वर्तिका नन्दा का नाम अपरिचित नहीं है। पंजाब में जन्मी वर्तिका ने अपराध पत्रकारिता जैसे चुनौतीपूर्ण क्षेत्र को चुना। इस क्षेत्र में कई नये प्रयोग भी किए। पत्रकारिता के क्षेत्र में नये-नये प्रयोगों के माध्यम से अपराधों के प्रति जागरुकता लाने का प्रयास किया। जेल में बन्द सजायफ्ता और अपराधियों को लेकर मीडिया का उपयोग सकारात्मकता से किया। मीडिया और साहित्य के जरिये महिला अपराधों के प्रति जागरुकता लाने के लिए वर्तिका को कई पुरुस्कार/सम्मान प्राप्त हुए।

वर्तिका कई विषयों पर लिखती हैं। उनके काव्य जो चर्चित रहे वे हैं 'मधुर दस्तक', 'थी, हूँ ... रहूँगी', 'रानियाँ सब जानती हैं', यह आलेख 'थी, हूँ...रहूँगी' संग्रह में संकलित कविताओं पर केन्द्रित है। इस संग्रह में वर्तिका ने अपराध पर काम करते-करते जो देखा, सुना, महसूस किया उन्हें शब्दों में उतारा है। उनकी कविताएँ, उनके अनुभव से उपजी हैं। वे अपने अनुभव को शब्द देती हैं। उनकी कविता 'बस यों ही' में वे अपने इसी अनुभव को बताती हैं। ईश्वर को हम सब मानते हैं। जब भी उसे याद करते हैं। फरमाइश कर देते हैं। कोई कभी कष्ट हो झट से ईश्वर से उसे हर लेने को कहते हैं कोई भी कमी हो हमें प्रभु याद आ जाते हैं। वर्तिका ने इन्हीं बातों पर गौर किया और उसे कविता में बस यों ही कह दिया। वे कहती हैं हम भगवान को अपनी फरमाइशों की लिस्ट बना कर ऐसे दे देते हैं जैसे परचून के समान की लिस्ट हो। मोल-भाव भी सब्जी मंडी की तरह ही करते हैं—

मोल भाव भी किया वैसे ही
कि पहली नहीं है

लघुकथाओं में प्रतिबिम्बित मानवीय संवेदनाएँ

—डॉ. नीतू परिहार
सह आचार्य एवं विभागाध्यक्ष
हिन्दी विभाग
मोहनलाल सुखाड़िया विश्वविद्यालय
उदयपुर (राज०)

लघुकथा साहित्य की वह गद्य-विधा है जिसमें बहुआयामी मानव-जीवन के किसी एक पक्ष का सहज, स्वभाविक एवं प्रभावी रूप व्यक्त होता है। आकार की लघुता, लघुकथा की अनिवार्य शर्त है। लघुकथा का फलक छोटा होता है, किन्तु छोटा आकार कथा की संवेदना को सीमित नहीं करता। लघुकथा के लिए भूमिका का स्थान नहीं होता लेखक सीधे विषय पर आता है। लघुकथा में यह विशेषता रहती है कि वह कम शब्दों में अधिक बात कहती है। बिहारी के दोहों के समान 'देखन में छोटे लागे, घाव करे गम्भीर'। वरिष्ठ साहित्यकार कमल किशोर गोयनका ने लघुकथा को परिभाषित करते हुए कहा है—"लघु का अर्थ यह है कि वह कहानी की तुलना में निश्चित ही ऐसी विधा है जिसका आकार लघु है और लघु आकार के लिए उसकी कथा का लघु होना अनिवार्य है क्योंकि कथा की लघुता ही प्रमुख रूप से 'लघुकथा' की एक विशिष्ट कथागत विधा का स्वरूप प्रदान करती है।"[1]

लघुकथा अपनी बात को बहुत छोटे से में कहने का सशक्त माध्यम है। आज के व्यस्तमय जीवन में लघुकथा के पाठकों की संख्या निरन्तर बढ़ती जा रही है, कारण कम समय में लघुकथा का पढ़ा जा पाना। आज के समय में लघुकथा

संत चरणदास की भक्ति चेतना

डॉ. नीतू परिहार

ईश्वर से प्रेम करना या ईश्वर में अपने को रत करना या डुबाना ही भक्ति है। दूसरे शब्दों में यह भी कह सकते हैं नित्यानुसार सांसारिक व्यवहार करते हुए, परमात्मा में लीन रहना भक्ति है। भक्ति की भावना निश्छल और शुद्ध हृदय में ही जाग्रत होती है, जहाँ स्वार्थ और अभिमान जैसे विकारों का स्थान नहीं। यह भी सच है कि भगवान की कृपा के बिना हम उसकी ओर आकृष्ट नहीं हो सकते। जब तक हमारे भीतर अच्छे संस्कारों का उदय नहीं होता, तब तक ईश्वर की अनुकम्पा भी नहीं होती।

हिन्दी साहित्य में भक्तिकाल को स्वर्ण युग कहा गया है। इस युग में भक्ति के अनेक रूप देखने को मिले हैं। भक्ति की अनेक धाराएँ बहती हुई दिखाई दीं। मार्ग चाहे कोई भी रहा हो, सबकी मंजिल एक ही थी—वो थी, उस परमात्मा की प्राप्ति। भक्तिकाल में ही निर्गुण भक्ति में ज्ञानाश्रयी शाखा को संत काव्य के नाम से जाना जाता है। संत साहित्य ने हिन्दी साहित्य को बहुत समृद्ध किया है। अनेक संतों की वाणियों ने भक्ति की जो धारा बहाई उसमें जनसमूह आकंठ डूबता-तिरता रहा। कबीर, नानक, रैदास, दादू, सुन्दरदास, मलूकदास आदि अनेक ऐसे संत हैं, जिन्होंने अपनी बाणियों से भक्ति का प्रचार-प्रसार किया तथा समाज को मिथ्या आडम्बरों, रूढ़ियों से मुक्त कराने का प्रयास किया। संत बहुसंख्यक जनता के वास्तविक प्रतिनिधि थे। उन्होंने जनता को जात-पाँत, अन्धविश्वासों से ऊपर उठाकर ईश्वर-भक्ति की ओर उन्मुख किया। समाज के विविध वर्गों के बीच की खाई को भी संतों ने पाटने का काम किया। संतों के विषय में डॉ. रांगेय राघव कहते हैं—"जब संसार में कार्ल मार्क्स नहीं था, जब संसार में द्वंद्वात्मक भौतिकवाद का चिन्तन नहीं था, तब भी मनुष्य अन्याय के प्रति लड़ता था और यह संघर्ष मध्यकाल के संतों में हमें दिखाई देता है। वे सब निम्न जातियों की मुक्ति के लिए हुए स्वर थे।"

मध्यकाल में भ्रमित जनता को संतों ने अपनी बाणियों से सहज भक्ति से ईश्वर की ओर ले जाने का प्रयास किया। घोर निराशा के समय में संतों ने समाज में फैली कुरीतियों पर गहरी चोट की, जाति-पाँति के भेदों से परे जाकर हर वर्ग को

देश प्रेम और आँचलिकता का दस्तावेज : डॉ. निशंक का मेजर निराला

डॉ. नीतू परिहार

डॉ. रमेश पोखरियाल 'निशंक' जाने-माने साहित्यकार हैं। उनका लेखन के प्रति लगाव, निष्ठा उन्हें सतत क्रियाशील बनाये रखता है। 'मेजर निराला' निशंक जी का चर्चित और प्रसिद्ध उपन्यास है। यह आलेख इसी उपन्यास पर केन्द्रित है।

उपन्यास के कथानक का प्रारम्भ फ्लैश बैक स्टोरी अर्थात् पूर्व दीप्ति से होता है। मेजर निराला पन्द्रह वर्ष जेल में सजा काट चुकने के बाद, जेल से रिहा होने वाला है। रिहा होने से पूर्व ही वह अपने बीते हुए समय पर विचार कर रहा है।

मेजर निराला जांबाज, बहादुर और देशभक्त मेजर था फौज का। वह अपने सीनियर अफसरों की आँखों का तारा था। भारत-पाक युद्ध में उसने अपनी वीरता से सबको बहुत प्रभावित किया। यही कारण था कि निराला के अफसरों ने युद्ध के लम्बा चलने की आशंका के चलते उसे जबरन छुट्टी पर भेज दिया ताकि युद्ध के अंतिम समय में उसका उपयोग कर सके।

मेजर निराला जितना अपने देश से प्रेम करता है उतना ही प्रेम वह अपने गाँव और परिवार से भी करता है। छुट्टियों में जब गाँव आता तो पूरे मन से वहीं रहता। मेजर को उसके साथी जब छुट्टियों में घूमने-फिरने को कहते हैं और अपने यहाँ बुलाते हैं तो वह कहता है, मेरी छुट्टियाँ तो गाँव के

Abstract

Recent years have witnessed awareness of environmental issues which has led to the development of green materials for drug delivery which are environment friendly. The pharmaceutical industry has paid close attention to bioresins and biopolymers as a means of developing new drugs and drug delivery systems. The biomedical scientists are looking forward to use bioresin and biopolymer composites in drug delivery as they are non-toxic, biodegradable, and affordable. They have broad range of release characteristics and do not have serious side effects on human body which are associated with synthetic polymers. Plant derived bioresins and plant and animal derived biopolymers have applications in drug delivery as beads, microparticles, implants, nanoparticles. They are employed as biomatrix in composites to control the drug release, to modify the release, gelling agents and viscosity enhancers etc. Food grade bioresins and biopolymers are employed in formulation of nutraceuticals. Further nanocomposites of bioresins and biopolymers are employed for treatment of various diseases like cancer, cardiovascular diseases, diabetes and other chronic metabolic diseases.

CHAPTER 16

Bioresorbable polymers for wound healing

Sheikh Shahnawaz Quadir[1], Dinesh Puri[2], Garima Joshi[1], Deepak Choudhary[1], Sanket Kumar[1], Monika Singh[3], Shalini K. Sawhney[3]

[1]Department of Pharmaceutical Sciences, Mohanlal Sukhadia University, Udaipur, Rajasthan, India

UNCORRECTED PROOF

16.1 Introduction

Over the last decade, polymers have played a vital role in medicine. Among these, bioresorbable polymers have gained increased attention due to their unique potential in medicinal formulations and represent a diverse family in the field of biomaterials. The term biomaterial was coined in 1982 at NIH Consensus Development Conference, describing clinical uses of biomaterials. It is defined as "any substances or a combination of the substances other than drug which is either natural or synthetic in nature can be used in any period of time for the treatment, replacement or augmentation of any tissue, organ or a function of the body." Other definitions include that in the William Dictionary of Biomaterials (1999), which states that "nonviable materials which is utilized in the medical devices, intended to interact with the biological system", and also "A material which is synthetic, natural or modified natural material (other than drug) intended to interact with the biological system or a part of system that are able to treat, replace or augment a tissue, organ or a function of the body" as described in Dorland's Medical Dictionary (Pertici, 2017).

Bioresorbable compounds are those compounds which alter their chemical and physical structure when they came into contact with a biological system. If a compound is bioresorbable in nature, by applying correct conditions in the presence of fungi, bacteria, or microorganisms, it will automatically break down to its basic structure. The key benefits of such compounds include that they degrade without leaving any toxins behind. The word bioresorbable means biodegradable or naturally ab-

Bioresorbable Polymers and their Composites
© 2024.
ISBN 978-0-443-18915-9, DOI: 10.1016/B978-0-443-18915-9.00008-2

sorbing, which is used to define the process of breaking down by nature. However, bioresorption highlights the process which leads to the slowly disintegration of a compound into fractions inside the human body. When this compound comes into contact with body fluids, it alters its physicochemical properties resulting in physical, chemical, biological, and mechanical characteristics among the compounds and neighboring environment. These compounds are easily metabolized without showing any toxic effects and then cleared from the body (Agubata et al., 2021).

The major utilized bioresorbable compounds in medicine are ceramics, and polymeric and metallic materials. Bioresorbable polymers have been described as "today's material." In the current era, bioresorbable polymers have attracted the attention of researchers and scientists due to their potential in the tissue engineering and biomaterials fields. Meanwhile, in medicine, bioresorbable polymers possess significant applications in wound healing (i.e., sutures, adhesives, staples, etc.) and controlled drug delivery. They are also used in ligaments for orthopedic devices, along with nonwoven materials and scaffolds in tissue engineering. These bioresorbable polymers also offer great applications in a number of domains such as dental, drug delivery, biological devices, biosensors, nanoparticles, and nanocarriers, as well as for in vitro diagnostic tools, etc. (Daniel, 2021).

Wounds can be defined as any lesion which occurs to the skin or other body tissues either by cuts, scratches, scrapes, or other accidental damage. Hence, for the treatment of such wounds, wound healing is needed. To regenerate and repair dermal and epidermal tissues, dressings are widely used in the wound-healing process. Wound dressing materials are materials which act as a barrier to foreign particles, oxygen, and moisture to combat and protect against microorganisms (Mogoşanu and Grumezescu, 2014). A passive dressing is important for maintaining optimum moisture, which helps in stimulating the wound-healing process. An ideal passive dressing material is one which influences the local cellular response for the treatment of wounds and burns such as cellulose, collagen, alginates, hydrogels, foams, cotton, hydrocolloids, etc. (Cornelius et al., 2006). These materials offer various key benefits in wound healing, e.g., maintenance of suitable moisture levels in wounds, minimizing the pain and itching, cleansing of damaged tissues, and eliminating dead spaces and nonviable tissues (Sawant et al., 2012). Some of these materials which are naturally available can progressively improve

UNCORRECTED PROOF

wound healing due to their emollient, antimicrobial, antiinflammatory, antioxidant and epithelializing properties.

Skin tissues have their own key potential, including structural organization and self-repairing ability. However, once they become injured by sufficiently large lesions, healing and recovery become suboptimal. In such cases, bioresorbable polymers play a vital role by restoring the native tissues or replacing them with engineered alternatives. This chapter emphasizes the factors which influence the healing process and the important applications of bioresorbable polymers in wound healing. It provides a framework for understanding the strategies of such polymers that could be key in the development of future therapeutic applications.

16.2 Wound-healing process

A wound is a skin lesion which occurs due to physical, chemical, thermal, or other tissue or systemic pathology. A wound is categorized on the basis of its severity, such as partial, superficial, or full thickness. The partial-thickness wound may have damage to the superficial layer, i.e. the epidermis (up to the dermal layer), and healing can take a few weeks. Superficial wounds only affect the epidermis, but healing can be successful through unaffected keratinocytes. The most difficult to treat and severe wounds are full-thickness wounds which can take several weeks to heal and still be suboptimal. These wounds include major damage to both the tissues of the epidermis and dermis (Mogoşanu and Grumezescu, 2014). The above-listed wounds occurs in three stages, i.e., inflammation, proliferation, and remodeling (Danti et al., 2017).

Inflammation: In the inflammatory process, platelets play a vital role by forming a fibrin clot soon after the injury which permits the infiltrating cells to gather in the lesion area to prevent bleeding. Additionally, these platelets attract growth factors by initiating a cascade of events such as monocytes, neutrophils, and fibroblasts. They also induce fibroblasts to secrete fresh extracellular matrix.

Proliferation: The second process of wound healing is categorized as reepithelialization and connective tissue regeneration. Reepithelialization is a process started by proliferating keratinocytes which travel toward the lesion site. These new blood vessels develop side by side and fibroblasts gather from nearby areas to deposit extracellular matrix molecules (collagen fibers, elastin, glycosaminoglycan) and granulocytic tissues.

UNCORRECTED PROOF

Remodeling: The final step in wound healing may take many year until the restoration of the entire dermis through constant tissue remodeling. This step proceeds by replacing collagen type III with collagen type I through the secretion of matrix metalloproteinase. There are also some wounds which occur due to pathological and disease conditions, such as diabetes, which are unable to heal completely. Hence, such wounds become chronic by sustaining inflammatory events which become difficult for the growth factors to perform a healing function, resulting in the development of pathological constraints such as tumors and persistent infections.

16.3 Factors affecting wound healing

There are various factors that may impede the wound-healing process. In simple terms, those factors which affect the repair mechanism are divided into local and systemic. The local factors are those which directly damage or influence the process of wound healing by altering its characteristics, and systemic factors are those which affect the healing abilities of an individual in healthy or diseased condition (Fig. 16.1). In the majority of cases systemic factors occur due to local factors which influence wound healing (Guo and DiPietro, 2010).

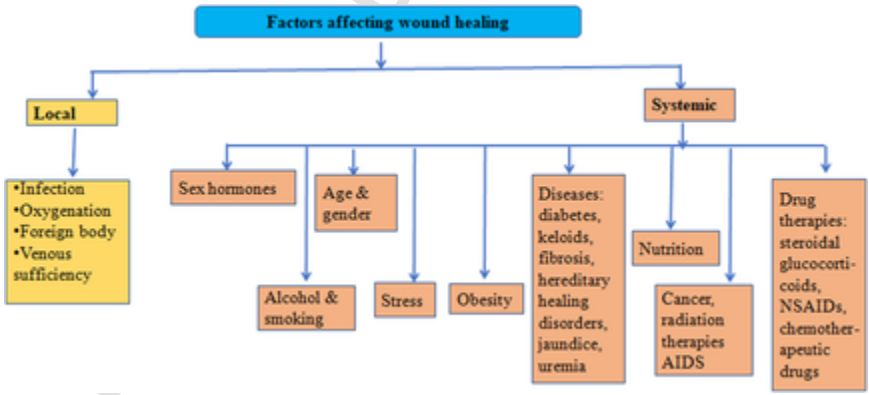

Figure 16.1 Factors affecting wound healing.

UNCORRECTED PROOF

16.3.1 Local factors that influence the healing process

16.3.1.1 Oxygenation

Oxygenation is crucial for the production of energy by means of ATP, cell metabolism, and for recovery from almost all types of wounds. It possesses several benefits in healing, such as the protection of wounds from infection by promoting angiogenesis, enhancing keratinocyte uptake, migration, and reepithelialization. It also promotes fibroblast proliferation around wounds along with the formation of collagen. Moreover, it increases the level of superoxide production with the help of polymorphonuclear leukocytes as a primary dependent oxygen factor (Bishop, 2008). There are several systemic conditions such as age and diabetes which can decrease the vascular flow, resulting in the development of hypoxic wounds due to poor tissue oxygenation.

Healing is diminished for those wounds which are unable to restore oxygen. A temporary lack of oxygen (hypoxia) can activate wound healing only if it happens for a long time, otherwise wound healing can be delayed. A lack of oxygen can impact cytokine and growth factor production. Cytokines formed due to a lack of oxygen include transforming growth factor-beta, platelet-derived growth factor, vascular endothelial growth factor, tumor necrosis factor, etc. ROS such as hydrogen peroxide and superoxide are majorly involved in normal wound healing and behave as cellular messengers to promote the wound-healing process, cell motility, cytokine action, and angiogenesis. Hypoxia and hyperoxia are responsible for enhancing ROS demand. However, on other hand, a higher level of ROS production can damage tissues (Rodriguez et al., 2008). To conclude, proper oxygen supply is essential for the success of the wound-healing process.

16.3.1.2 Infection and foreign bodies

Once a lesion is present on the skin, microorganisms gather at the skin surface and enter the underlying tissues. The level of the infection and replication state of the microorganisms affect whether the wounds are colonized, contaminated, or spread the invasive infection. The availability of nonreplicating microorganisms on wounds is identified as contamination. Meanwhile, the presence of replicating microorganisms on a wound without any tissue damage is described as colonization. Local infection and critical colonization are found at an intermediate stage where

UNCORRECTED PROOF

microorganisms can replicate and local tissue actions are started. An invasive infection is defined as the availability of replicating microorganisms inside a wound (Harding and Edwards, 2004).

On the other hand, inflammation is a basic response in the wound-healing process and an essential factor for the removal of contaminated microorganisms. If microbial removal is not completed, inflammation is sustained for a longer duration. Due to such conditions, bacteria and endotoxins both enhance cytokine production (IL-1 and TNF-alpha) which increase the inflammatory phase. If this happens for a longer time, the wound is considered as chronic and is difficult to heal. Moreover, such a prolonged inflammatory state may elevate the production of metalloproteases which are responsible inhibiting the extracellular matrix in wounds (Menke et al., 2007).

16.3.2 Systemic factors that influence the healing process

16.3.2.1 Age

As per WHO, the over 60 years age group is growing faster than any other age group. Higher age of individuals is one of the critical risk factors in the impaired wound-healing process. Many clinical and animal studies conducted at the molecular level have revealed that higher age can adversely impact wound healing (Keylock et al., 2008). In the aged individual, altered inflammatory reactions, i.e., T-cell infiltration, chemokine formation, and lower phagocytic volume around the wound environment, can delay the wound healing. An animal study in aged mice compared with young mice revealed delayed angiogenesis, collagen production, and reepithelialization. In general, there are small differences between young and aged individuals in terms of wound healing. A review study of age-related changes revealed that the each step of wound healing for aged persons showed higher platelet aggregation, higher uptake of inflammatory mediators, delayed permeation of macrophages and lymphocytes, lowered growth factor secretions, and delayed reepithelialization, angiogenesis, and collagen production (Gosain and DiPietro, 2004).

16.3.2.2 Sex hormones in aged individuals

Compared to aged females, aged males are more affected by delays in the wound-healing process due to sex hormones. A female estrogen (estrone), male androgen (testosterone), and there steroidal precursor (dehy-

UNCORRECTED PROOF

droepiandrosterone) have significant effects on the wound-healing process (Gilliver et al., 2007). A study revealed that the expression of genes among elderly men and young women was totally estrogen regulated. Numerous genes associated with wound healing are affected by estrogen, which enables matrix production, and inhibits protease and regeneration of tissues, and the genes those are involved in inflammation (Hardman and Ashcroft, 2008).

16.3.2.3 Stress

Stress has a significant effect on human health and social behavior. Several diseases are associated with stress, such as diabetes, wounds, CVS, and cancer (Vileikyte, 2007). Clinical research has revealed that both humans and animals with physiological stress can have a hampered wound-healing process. A student with the stress of academic examinations and a caretaker for a person with Alzheimer's have delayed wound-healing processes. Stress is responsible for the up-regulation of glucocorticoid hormones as well as lowering the amount of proinflammatory cytokines (IL-1β, TNF-α, and IL-6) at the wound area. It also inhibits the progression of chemoattractants (IL-8 and IL1-α) which are essential for the initial inflammatory step during the wound-healing process (Boyapati and Wang, 2007).

Moreover, Th1 responses are essential during the starting phase of wound healing, and are regulated by the glucocorticoid cortisol as an antiinflammatory agent. Hence, physiological stress can impair and delay healing at the wound site via reduced cell-mediated immunity (Godbout and Glaser, 2006). Other negative stress factors such as anxiety and depression affect health and behavior as well as being responsible for delaying wound healing. The effects of stress on wound healing are summarized in Fig. 16.2.

16.3.2.4 Diabetes

An individual who is affected by diabetes shows an impaired healing process in acute wounds. Much of this population is affected by chronic nonhealing diabetic foot ulcers (DFUs). DFUs are a severe condition of diabetes that occur in about 15% of the total diabetic population. A patient with diabetes can experience poor wound healing from both DFUs as well as acute cutaneous wounds due to a variety of intricate pathophysiological processes. DFUs arise to hypoxia, as with venous stasis ill-

UNCORRECTED PROOF

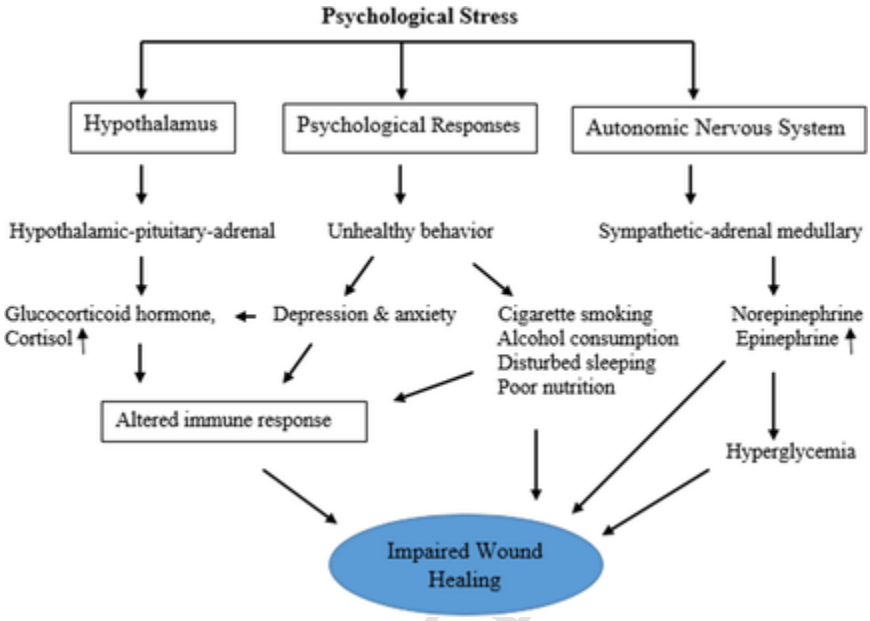

Figure 16.2 The effects of stress on wound healing.

ness and chronic nonhealing wounds. By elevating the concentration of oxygen radicals, hypoxia can exacerbate the primary inflammatory actions and lengthen the healing process. Diabetes-associated wounds are considered to have a number of dysregulated cellular causes, including inadequate T-cell immunity, faulty leukocyte chemotaxis, phagocytosis, bactericidal activity, and dysfunctioning of epidermal cells and fibroblasts (Woo et al., 2007). Some of the other causes are described in Fig. 16.3.

16.3.2.5 Medications

Numerous drugs have the potential to alter the wound-healing process, including those that hamper platelet function, clot development, inflammatory action, and cell proliferation. Only those drugs categories that are frequently taken and possess major effects on healing are discussed here, such as NSAIDs, glucocorticoid steroids, and chemotherapy therapies.

16.3.2.5.1 Glucocorticoid steroids

The glucocorticoids are systemic antiinflammatory drugs that are well recognized as hindering wound healing by suppressing cellular wound

UNCORRECTED

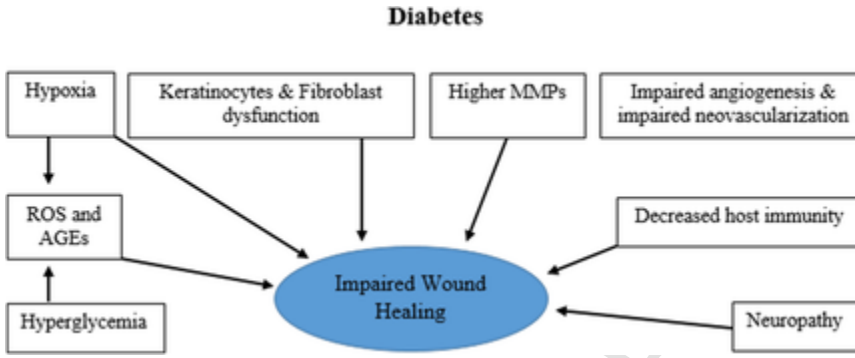

Figure 16.3 Effects of wound healing in diabetes. *AGEs*, advanced glycation end products; *MPPs*, matrix metalloproteases; *ROS*, reactive oxygen species.

responses. i.e., the proliferation of fibroblast and collagen production. These steroids form inadequate granulating tissues and lower wound contraction in the healing process. A critical transcriptional factor associated with wound healing, i.e., HIF-1 (Hypoxia-inducible factor-1), is also inhibited by glucocorticoids (Wagner et al., 2008). Compared to systemic application, topical application of glucocorticoids has quite different effects as it promotes the wound-healing process. Chronic wounds treated with topical low-dose corticosteroids have been shown to heal more rapidly, cause less pain and exudate, and encourage hypergranulation tissue formation in almost 79% of instances (Hofman et al., 2007).

16.3.2.5.2 NSAIDs

Ibuprofen is one of the nonsteroidal antiinflammatory drugs (NSAIDs) frequently used to treat inflammation, control pain, and treat rheumatoid arthritis. A low dose of aspirin is frequently used as a primary preventive treatment option for cardiovascular disease but not as an antiinflammatory drug due to its antiplatelet properties (Pertici, 2017). There is little evidence to support the claim that short-term use of NSAIDs impairs wound recovery. However, it remains unclear whether long-term NSAIDs affect how well wounds heal. Moreover, in animal studies, ibuprofen has been shown to have antiproliferative properties on wounds, resulting in lowering of fibroblast content and wound contraction, along with delayed epithelialization and impaired angiogenesis (Pieringer et al., 2007).

UNCORRECTED PR

16.3.2.5.3 Chemotherapeutic drugs

The majority of chemotherapies work by slowing down the cellular metabolism, accelerating cell division, and promoting angiogenesis, all of which are essential for an effective wound-healing process. These drugs prevent the production of DNA, RNA, and proteins, which lower the fibroplasia and neovascularization of tissues. Chemotherapeutic drugs delay cell migration into the wound, decrease early wound matrix formation, lower collagen production, impair the proliferation of fibroblasts, and inhibit the contraction of wounds (Kirchner et al., 2003).

16.3.2.6 Obesity

Numerous infections or diseases, as well as health issues such as diabetes, ischemic heart disease, cancer, hypertension, and delayed wound healing, are known to be made more likely by obesity. People affected by obesity experience several wound complications, such as venous and pressure ulcers, skin wound infections, seroma, and hematoma development. Obese patients receiving bariatric and nonbariatric procedures have been shown to have a higher frequency of wound problems. Obese people experience a higher rate of surgical site infections and many of these issues occur in subcutaneous adipose tissues due to hypoperfusion and ischemia. This situation also occurs due to lowered intake of antibiotics. Increased tension on the edges of surgical wounds typically occurs in obese patients, resulting in wound dehiscence. Due to wound tension, tissue pressure rises significantly, which hampers the microperfusion process and lowers the capabilities of wounds to consume oxygen (Franz et al., 2007).

16.3.2.7 Alcohol consumption

The use of alcohol hinders the wound-healing process and enhances the risk of infection as per a clinical and animal study report (Anaya and Dellinger, 2006). Due to alcohol exposure, either acute or chronic, in more than half of traumatic events, the impact of alcohol on the repair mechanism is extremely clinically significant. The consumption of alcohol lowers the defense mechanism and being intoxicated at the time of injury increases the likelihood of wound infection (Szabo and Mandrekar, 2009).

UNCORRECTED PROOF

16.3.2.8 Smoking

Smoking increases the risk of various malignancies, such as stroke, heart, vascular disease, lung disease ,etc. Similarly, smoking has long been recognized as having detrimental impacts on wound healing (Choudhry and Chaudry, 2006). One study revealed that patients who smoke after surgery experience delayed wound healing and also a number of issues such as wound rupture, infection, leaking, necrosis, epidermolysis, and lowered tensile strength of wounds. In the field of oral surgery, smokers have been found to have lower recovery after both conventional oral surgery and the installation of dental implants (Ahn and Mulligan, 2008).

16.3.2.9 Nutrition

Nutrition has been acknowledged for more than a century as a critical component that influences the wound-healing process. It is clear that inadequate nutrition or specific nutrient deficiency can significantly affect wound healing following trauma and surgery. Patients who are malnourished and have chronic or delayed healing frequently require specialized nourishment. The healing process can be impacted by the metabolism of carbohydrates, proteins, fats, vitamins, and minerals (Balaji, 2008).

16.4 Properties of bioresorbable polymers

For the manufacturing of engineered tissue products, the choice of biopolymer is crucial. Although the traditional selection principle for secure, stable, and inert substances still applies, it has been found that any artificial substances ingested by the patient will have biological reactions. As each biopolymer application necessitates a different environment for cell–cell communication, it is crucial for the engineered tissue product manufacturer to have a variety of biopolymer options available (Zhang et al., 2014). Such applications include:

A. It should support the development of new tissues through the interaction among cells and their potential to obtain nutrients, growth factor, and optimized active pharmaceutically ingredients.

B. It should inhibit the cellular properties of tissue growth where surgically induced adhesions are detrimental.

UNCORRECTED PROOF

C. It must lead to tissue responses by increasing the cellular reaction of one and inhibiting the other.
D. It should improve cell–cell connections and cellular activity, such as the formation of ECM, proliferation, and fibroblast attachment.
E. It should inhibit cellular connectivity, such as the connectivity of platelets to vascular grafts.
F. Inhibition of biological activity such as in organ transplantations by blocking antibodies against grafted cells.

When tissue recovery or modifications are the prime object of engineered tissue products, bioresorbable polymers are appropriate; however, they are not appropriate when long-lasting material stability is needed. Hence, bioresorbable polymers also require features such as:

A. Manufacturing feasibility, as well as an excess amount of polymers available commercially.
B. The proficiency to convert the polymer into the final product.
C. The mechanical characteristic that interact in short-term functioning but do not interfere with long-term functioning.
D. Minimum or nontoxicity of breakdown products, in both systemic and local tissue reactions.
E. Possibilities for the development of drug-delivery systems for use in the sustained release of active pharmaceutical ingredients.

Natural and engineered natural substances, along with metals, synthetic polymers, ceramics, and composites, are among the various substances that are mostly used in clinical applications. Metals, including their alloys, are employed for implants in dental and orthopedic use because of their mechanical potential, such as ductility, toughness, and increased strength. Nevertheless, a metallic implant may have issues that are serious enough to necessitate a second surgery to remove the device, such as irritation brought on by corrosive and erosive conditions in biological systems, secondary fracture of conducted bone, and development of sterile implants. Ceramics and glasses, which can be chemically bioactive or nonbioactive in nature, are utilized in a number of biomedical applications, mostly for rebuilding missing bones, but because of their brittle nature, they are avoided in load-bearing applications (Arnold and Barbul, 2006).

Polymers are less strong and ductile than ceramics, glasses, and metals, however they are commonly utilized for exchanging, increasing, supporting, or fixing live tissues due to their diversity, simplicity, and bio-

UNCORRECTED PROOF

compatible nature. It is feasible to develop composites by mixing polymers, ceramics, and metals to acquire unique qualities which are not present in a single material to develop customized devices for use in numerous biological sectors. Due to the structural similarity in living tissues which are formed of macromolecular composites, synthetic polymer composites are widely appealing biomaterials. The formation of engineered scaffolds, simple sutures, fixing screws, gauze strip, and bone replacements using bioresorbable polymers is a common practice. They do not require any secondary method to remove the implant or to initiate the tissue recovery in the matrix. The major outcome in the development of biomaterial research in the last 30 years has been the gradual transition from bio-stable prostheses to bioresorbable implants (Zhang et al., 2014).

16.5 Bioresorbable polymers for wound healing

Natural polymers offer a variety of benefits in regenerative medicinal therapy for the enhancement of wound healing, such as biodegradability, biocompatibility, and similarity to the extracellular matrix. Natural polymers are engaged in the repair of injured tissues and subsequently in skin regeneration by initiating and promoting the wound-healing process (Huang and Fu, 2010). Biomaterial hydrogels are used commercially, such as in pharmaceuticals and biomedicals, due to their unique 3D cross-linked structures that are soaked in aqueous or biological fluids for wound treatment, drug administration, organ replacement, and engineered tissue products (Das et al., 2012). Additionally, radioactivity studies are used to create innovative biomaterials based on biodegradability, nontoxicity, and bio-renewable polymers. As a result, hydrogels made of naturally cross-linked polymers are utilized for the healing of wounds and skin burns (Haji-Saeid et al., 2010). The natural bioresorbable polymers for wound healing are described in the following subsections.

16.5.1 Polysaccharides

Polysaccharides are mainly introduced in the form of hydrogels. Some are primarily used for the treatment of wounds and skin burns. The polysaccharides are divided on the basis of their nature, such as those are neutral in nature, i.e., dextrans, glucans, cellulose; acidic in nature, i.e.,

UNCORRECTED PROOF

alginic, hyaluronic acids; basic in nature, i.e., chitin, chitosan; or sulfated in nature, i.e., heparin, keratin, chondroitin, etc. (Kennedy et al., 2001).

16.5.1.1 Homoglycans

Homoglycans are biocompatible biopolymers that are utilized locally to alter the cellular activities involved in wound healing. Starch, dextran, cellulose, or their modified compositions can be used in the manufacture of nanofiber matrices in the regenerative medicinal therapies sector, such as for wound healing and tissue engineering (Lee et al., 2009).

16.5.1.1.1 α-Glucans

The common yeast-like fungus *Aureobasidium pullulans* forms pullulan (1-4),(1-6)-d-glucan from starch (Dothioraceae). A pullulan by-product was synthesized using a chemical cross-linking method for antibacterial release during wound healing via a superabsorbent polysaccharide-based hydrogel. Hydrogels possess extraordinary water-absorbing capabilities, with a swelling ratio up to 4000% and are also noncytotoxic, offering rapid hemostasis, while inhibiting fluid aggregation and enabling wound bed dryness. Additionally, drugs such as antibacterials or antimycotic therapies may be encapsulated into hydrogels to protect wounds and skin burns against microbial biofilm invasion (Li et al., 2011).

16.5.1.1.2 β-Glucans

β-Glucans possess the capabilities to form single and triple helical durable gel structures, while numerous forms of (1-3)-d-glucans can be isolated from fungi, yeast, and grains to identify the pharmacological and immunological properties. A study conducted by Lehtovaara et al. revealed that highly pure yeast-derived insoluble (1-3)-d-glucan considerably minimized skin irritation, blocked adipogenic division, and aided the wound-healing process (Lehtovaara and Gu, 2011; Vetvicka and Vetvickova, 2011).

16.5.1.1.3 Dextrans

Dextran that has been modified to possess heparin-like qualities is known as carboxymethyl benzalamide sulfonate dextran (CMDBS), which is utilized for the treatment of wounds and skin burns. In general, CMDBS is a soluble polymer which possesses structural similarity with glycosaminoglycan heparin by enhancing the wound-healing process. In the majority of in vivo studies, it has been shown to be capable of inhibiting

UNCORRECTED PROOF

Staphylococcus aureus biofilms and promoting the cell proliferation and metabolism of various cells such as tumor, smooth muscle, and endothelial cells. Recently, cyclodextrins (hydrated) have been utilized as odor-control dressings due to their bucket-shaped structure which is capable of trapping and neutralizing water-insoluble particles. Cyclodextrin can be active for a long time than charcoal or serum proteins, which makes them excellent candidates to absorb odors more effectively (Logeart-Avramoglou and Jozefonvicz, 1999).

16.5.1.1.4 Cellulose

For chronic wound dressings, bioengineered cellulose is utilized superficially as a healing scaffold or matrix material, which minimizes discomfort and pain, and accelerates the healing process. Cellulose also possesses key benefits in wound healings such as enhancing granulation and epithelialization of partial- and full-thickness wounds. Various bioactive molecules, such as enzymes, hormones, vitamins, antioxidants, and antimicrobials, can be incorporated through a co-immobilization process using engineered cellulose for wound healing (Medusheva et al., 2007).

16.5.1.1.5 Chitin and chitosan

The most common natural amino polysaccharide is chitin (polu-N-acetyl-glucosamine), which is readily accessible throughout the year like cellulose. It makes up the majority of the exoskeletons of insects, crustaceans, and vertebrates, and also the cell walls of fungi. Chitin is transformed into chitosan (poly-N-acetyl-glycosaminoglycan) via the alkaline deacetylation process and by reacting the shells of shrimps with sodium hydroxide (Morganti et al., 2011). Several chitin and chitosan compositions with local hemostatic, antimicrobial, antiinflammatory, and wound-healing characteristic have been developed, such as water-soluble chitin ointment for wound-healing treatment (Han, 2005) and chitin-loaded silver nanoparticles as a bactericidal film for wound healing (Madhumathi et al., 2010).

16.5.1.2 Heteroglycans

Heteroglycans offer various potentials in the biomedical sector. Heteroglycans, namely pectins, agarose, alginates, gums, carrageenans, and glycosaminoglycans, are biodegradable, biocompatible, and possess unusual physicochemical properties, i.e., film/gel forming and thickening proper-

UNCORRECTED PROOF

ties of electrostatic composites. The development of heteroglycan fibers in the nanometric range using electrospinning technology may be advantageous for drug delivery and also regenerative medicinal therapies (Lee et al., 2009).

16.5.1.2.1 Alginates

Alginates are long repeating-unit polysaccharides with varying concentrations of residues from D-mannuronic and L-guluronic acid that are (1-4)-linked. Due to their hemostatic qualities, alginate-based wound dressings are frequently applied on skin burns and exuding or bleeding wounds. Alginates such as calcium, calcium-sodium, collagen, and gelatin are extremely absorbent natural fiber dressing materials developed from processed algae.

16.5.1.2.2 Agar and agarose

Agar and agarose fibers are developed by wet-spinning technology and are mainly utilized in biomedical and biomaterial applications for wound healing. A solvent containing DMSO:water in a ratio of 9:1 was used to construct continuous fibers in an ethanol coagulation bath. Agarose fibers that were homogeneous and of smooth texture exhibited significant water-swelling capabilities of 400%–500% as well as tensile strength of 30–50 MPa. Agarose fibers have been shown to be superior for swelling in water than agar fibers. Meanwhile, agaropectin has been shown to have flexibility issues (Bao et al., 2010).

16.5.1.2.3 Carrageenan

Carrageenan or carrageenins are a family of natural linear polysaccharides that are extracted from red edible seaweeds. They offer several potentials in the pharmaceutical, biomaterial, and food industries for thickening, gelling, and stabilizing properties. PVP-KC hydrogels were created by subjecting a combination of water systems such as poly(N-vinyl-2-pyrrolidone), kappa-carrageenan (KC), potassium chloride, and PEG to various gamma radiation dosages. These hydrogels were evaluated on various factors such as temperature, mechanical behavior, fluid uptake, swelling factor, pH, electrical conductivity, and bioadhesive property on the human skin to predict their potential in wound healing (Şen and Avcı, 2005).

UNCORRECTED PROOF

16.5.2 Glycolipids

Glycolipids are the complex lipids comprising carbohydrates linked via a glycosidic bond. Their main qualities include providing stability to the cell membrane and enhancing cellular recognition, which is important in terms of cell immunity as it permits cells to form bonds to develop tissues. Patients suffering from skin burns and wounds can benefit from topical glycolipids therapy consisting of galactose liposomes because of the rapid uptake of neutrophils and macrophages. The ability of macrophages to release cytokines and growth factors promotes tissue remodeling and the repair mechanism which is a key approach to wound healing. When compared to a control group, an experiment on mutant mice using 1-3-galactosyl transferase revealed the beneficial response of –Gal liposome at a daily dose of 10 mg (Galili et al., 2010).

16.5.3 Proteoglycans

Proteoglycans are essential proteins, covalently linked with the glycosaminoglycan chain that have a significant amount of macromolecules in the composition of extracellular matrix. Neoproteoglycans are the most biocompatible and biodegradable synthetic glycoconjugates developed from essential nanomaterials, proteins, or polymers that are covalently linked to the glycosaminoglycan chain and connected with the cells and proteins. Conjugates such as protein glycosaminoglycan, nano-glycosaminoglycan, and polymer glycosaminoglycan complexes are the three basic forms of neoproteoglycan which possess in vivo and in vitro tissue-engineered applications (Weyers and Linhardt, 2013).

16.5.4 Proteins and peptides

16.5.4.1 Vegetal proteins

Vegetal proteins are proteins available naturally from plants. These include soya, pulses, seeds, certain grains etc. These foods contain all the amino acids in an acceptable quantity. The treatment of wounds and skin burns can also be aided by some vegetal proteins. An ex vivo study performed on excised skin of rat using a combinational biomaterial composite of soya protein and sago starch which was cross-linked with glutaraldehyde was found to be effective in wound healing (Ramnath et al., 2012). Additionally, vegetal proteins such as soya and sodium caseinate-derived biomaterials offer significant advantages in wound healing and

UNCORRECTED PROOF

drug delivery due to their biocompatible and biodegradable natures (Silva et al., 2003).

16.5.4.2 Collagen

One of the most prevalent proteins found in the human body and skin is formed by fibroblasts and is known as collagen. Collagen offers several potential qualities such as enhanced wound-healing process at the cellular and molecular levels as well as aiding the development of new tissues and epithelialization of wounds. For the prevention and cure of partial/full-thickness wounds with low to high exudates, collagen dressings formulated from bovine, pig, or avian sources are mainly utilized. However, these dressings are avoided in severe skin burns and for the patients who are sensitive or allergic to these products (Murali et al., 2011). There have been many research works on the use of various collagen-based dressings and compositions for the treatment of wounds and burns, such as for deep wounds (collagen sponges), gingival wounds (collagen–glycosaminoglycan complex), oral wounds (resorbable collagen membrane), wound healing (DNA salmon–collagen film complex) (Shen et al., 2008), cutaneous wounds (collagen–minocycline hydrogels) (Ghica et al., 2011), skin grafting (collagen microfiber scaffolds) (Kempf et al., 2011for vascular grafts and wound repairing (collagen electrospun nanofiber scaffolds) (Fullana and Wnek, 2012), and modified collagen–alginic thermostable biopolymers for the treatment of wounds (Mitra et al., 2011).

16.5.4.2.1 Gelatin

Gelatin is a naturally available biopolymer mainly obtained from collagen, and also from various animal by-products. Nowadays, gelatin is mainly used in the pharmaceutical and biomedical industries for the development of drug-delivery applications and for wound healing due to its biocompatible and biodegradable dressings. To identify its healing properties, various gelatin-containing composition studies have been performed on the dorsal skin of rats, such as cross-linked gelatin-alginates, gelatin-hyaluronic acid sponges, and EGF-gelatin-based wound healing in conditions including excess tissue loss and nonhealed wounds, i.e., burns, diabetic foot ulcers, trauma, and static ulcers; bioresorbable gelatin films have also been used for the treatment of trauma and orthopedic injuries.

UNCORRECTED PROOF

16.5.4.2.2 Keratin

The intermediary fibrin proteins present in vertebrate epithelia and corneous tissues such as hooves, horns, and claws are collectively referred to as keratin. Due to its potential to treat proteolytic injuries, keratin and its derivatives have been utilized in chronic wounds to speed up healing. Keratin-based novel wound dressings with optimum potential have demonstrated controlled release behavior of growth factors and antibiotics.

16.5.4.2.3 Silk fibroin

Silk fibrin offers exceptional characteristics in the wound-healing process such as adhesion, absorption of exudates as well as being biodegradable and biocompatible with less inflammatory responses. Additionally, silk fibroin is utilized for the management of skin grafts, artificial ligaments, tendons, etc. It also serves as an excellent candidate in regenerative medicinal therapies such as silk fibroin and chitosan complex scaffolds for tissue regeneration (Gobin et al., 2005), carbon nanotubes for wound healing, SF–alginate combinational sponges for full-thickness wounds, and SF film biomaterials for wound treatment (de Moraes and Beppu, 2013).

16.5.4.2.4 Bovine serum albumin (BSA)

BSA is a protein derived from cattle. Due to anionic charge, BSA act as an intermediate bridge between tissues and cells and also acts as a carrier to transport fatty acids, vitamins, hormones, etc. Because of its binding capabilities, it also acts as a scavenger for the removal of toxic material such as pyrogens from the medium. BSA nanofibers are developed from the globular proteins in BSA medium without utilizing any chemical cross-linkers. Because of the fibrous characteristic of BSA it possesses various benefits in wound healing, suturing, and wound closure. It is used in various biomedical and pharmaceutical applications due to its biocompatible, biodegradable, and effective mechanical qualities (Zhu et al., 2011).

16.5.4.2.5 Enzymes

Enzymes are proteins that offer several applications in wound healing. Proteolytic and fibrinolytic enzymes, along with collagenase and papain, are effectively utilized in the epithelialization of wounds. In pectin film

UNCORRECTED PROOF

applied for wound healing, the development of prostaglandin H was drastically enhanced (Dror et al., 2008). Lysostaphin, a cell lytic enzyme, was formulated as antiinfective bandages immobilized on electrospun fibers through a solution of cellulose, such as cellulose–chitosan and cellulose–poly-methacrylate. However, enzymes are avoided in wound healing for patients affected by coagulation disorders (Miao et al., 2011).

16.5.5 Synthetic polymers

Synthetic polymers were developed chemically in laboratories, and are described as manmade polymers (Gobi et al., 2021). By increasing the mechanical and biocompatible potentials of individual components, synthetic and natural polymers can be used to create new kinds of materials.

A hydrophilic synthetic polymer, polyvinyl alcohol (PVA), is widely employed in a variety of biomedical applications (Gyles et al., 2017). PVA is possible due to the availability of hydroxyl molecules, which can help to form hydrogen bonds (Norouzi et al., 2021). Due to its poor hydrophilic properties, thick membrane, and inadequate flexibility, PVA is only occasionally used as a polymeric wound-dressing material (Venkataprasanna et al., 2020). A synthetic hydrophilic polymer is known as poly(ethylene glycol) (PEG) (Sahana and Rekha, 2018). Growth factors such as macromeres and epidermal growth factor are interlinked to each other through significant attraction. These can be used directly at the wound site. Mechanical, thermal, and PEG crystalline features are preserved by mixing polymer with chitosan and PLGA. Such PEG-based treatments are effective in diabetic wounds. These treatments speed up the healing process by promoting skin cell development, collagen deposition, and proliferation (Shahverdi et al., 2014). Methacrylic acid is a monomer used to develop the synthetic polymer known as poly(methacrylic acid) (PMAA). In order to merge bioactive compounds with carboxylic groups, such as drugs and inorganic nanoparticles, PMAA is highly recommended in biomedical applications due to its water-soluble and biocompatible nature (Lumbreras-Aguayo et al., 2019). This substances can alter noticeably in response to changes in the pH and iconic strength of the solution as well as having high swelling capabilities in water. N-vinylpyrrolidone (monomer) was used to develop a hydrophilic linear chain polymer known as polyvinylpyrrolidone (PVP) (Kausar, 2019). A lipophilic and semicrystalline synthetic polymer

UNCORRECTED PROOF

known as polycaprolactone (PCL) has significant crystalline and morphological properties (Mohamed and Yusoh, 2016). To enhance its mechanical capabilities, PCL has been formed by mixing with other polymers or combined with them. Another of the most widely utilized synthetic polymers in the biomedical sector is poly(lactic acid (PLA). Several other derivatives of PLA are available with its chiral structure, such as poly-L-lactide (PLLA) formed by L-polymerization and called L-lactide.

Electrospinning technology is the primary method to obtain synthetic polymers which have micropores and a highly specified surface area for the treatment of wounds and skin burns. Synthetic polymers for wound dressing offer occlusive or semiocclusive characteristics enabling them to act as a barrier to protect against the infiltration of microorganisms. They may be in the form of hydrogels, foams, or hydrocolloids. Exudates are entrapped by the polymer film which provides a moist environment to the wound. Various authors have developed synthetic polymer-based wound dressing materials, such as ciprofloxacin HCL-loaded polyurethane and dextran electrospun nanofiber. Carrageenan-hydrophilic polymer hydrogels, cellulose acetate, PLA, and PLGA infused with shikonin have been used for wound recovery due to their antimicrobial, antiinflammatory, and antitumor activities, in addition to PVP-based nanosilver alginate hydrogels. One study revealed that carboxy methyl-chitosan provides various in vitro and in vivo characteristics in wound healing, such as stimulation of fibroblasts and macrophages and the secretion of various cytokines.

16.6 Nanocomposites for wound healing

In the area of wound healing, an increasing number of novel nano-therapies have surfaced and are presently undergoing clinical research studies. Numerous nano tactics have been investigated focusing on various stages of wound repair, such as nanoparticles, nanocarriers, and nanomaterials. Nanoparticles (NPs) are one of the options that researchers are studying for wound healing due to their wide spectrum of antibacterial properties and quick efficiency with a minimum dose. Due to the inability to permit a cell barrier, conventional therapies for wound healing have limited success as compared to nanoparticles, which can permit entry effectively (Khan et al., 2019). Disruption of the cell membrane, changes to the

UNCORRECTED PROOF

genes, and inhibition of enzyme production are aspects of NPs' antimicrobial activity, which leads to cell apoptosis. In addition, nanomaterials (NMs) are smooth, flexible, and biocompatible wound-healing materials that act as a gas barrier, absorbent for exudates, and a shielding material against further damages or heat. There are two primary types of NMs used in wound healing: (1) NMs with inherent qualities useful for treating wounds and (2) NMs used as drug-delivery systems (Bhattacharya et al., 2019).

16.6.1 Nonpolymeric

There are several nonpolymeric NPs that are utilized in wound healing, including metal and metallic NPs, lipid NPs, and ceramic NPs, as discussed next.

16.6.1.1 Metal and metallic nanoparticles

Various metal-based NPs such as gold (AuNPs), copper (CuNPs), silver (AgNPs), zinc oxide (ZnO NPs), titanium dioxide (TiO_2), cerium oxide (CeO_2), yttrium oxide (Y_2O_3), and other metal-based NPs have been reported for their antibacterial and wound-healing properties. Silver has been used as a medicine for a very long time. For the management of open wounds, burns, and chronically infected wounds, many types of silver components, i.e., metallic silver, silver nitrate, and silver sulfadiazine are used currently (Rai et al., 2009). The use of AgNPs has recently drawn attention, particularly for the treatment of open wounds, as a result of the rise in pathogenic bacteria that are multidrug resistant and to reduce the use of antibiotics. Silver nanoparticles are the most researched nanomaterial of all nanoparticles because of their exceptional antibacterial properties. Silver NPs are more effective at demonstrating higher antibacterial property than traditional therapies because they have a large surface area to volume ratio, which improves their interaction with microbes. The phosphorus-containing compounds in microbial cells, such as DNA ,can also bind with silver NPs, as can sulfur-containing proteins anchored in bacterial membranes.

A study performed by Orlowski and co-workers formulated tannic acid modified silver NPs possessing higher antibacterial action against *P. aeruginosa* and *E. coli*. The data revealed that the prepared NPs showed better wound closure, formation of granulating tissues, and angiogenesis in a mouse wound model (Orlowski et al., 2018). Another study per-

UNCORRECTED PROOF

formed by Peng and co-workers developed CS-coated silver NPs. Their data showed that the prepared formulation possessed excellent biocompatibility and was effective against meticillin-resistant *S. aureus* in contrast to polyvinyl-coated silver NPs (Peng et al., 2017). Silver NPs with CS polyethylene glycol hydrogel have been produced as a treatment for diabetic chronic wounds (Masood et al., 2019).

16.6.1.2 Lipid nanoparticles

Researchers and scientists have become interested in lipid-based NPs recently due to their potential use as drug-delivery systems. In addition, lipid NPs can be modified to suit certain health issues and routes of administration. These systems are risk-free, economical, and provide protection to drugs from biological deterioration. Due to their minimal toxicity and excellent efficacy, lipid NPs are employed as drug-delivery carriers in sensitive tissues (Attama et al., 2012). Such lipid NPs include solid lipid nanoparticles (SLNs), nanostructured lipid carriers (NLCs) and drug–lipid conjugates.

In addition to reducing pain and infection, essential oil offers several properties in wound healing such as an antibacterial, relaxing, and quick recovery from wounds (Saporito et al., 2018). Although rosemary and eucalyptus leaf extract have the ability to heal wounds, these essential oil are naturally volatile and are rapidly broken down by oxidation, heat, light, and volatilization (Apostolides et al., 2013). Hence, SLN- and NLC-based carriers are employed that enclose these essential oils and maintain their biological activity (Gokce et al., 2012). A study by Saporito and co-workers (Saporito et al., 2018) developed eucalyptus and rosemary oil-loaded NLCs. They used coco butter and olive oil as solid and liquid lipids which possess higher natural stability, biocompatibility, and rapid wound-healing properties through dermal fibroblasts. This study revealed that the prepared formulation effectively provided higher healing and antimicrobial properties showing a synergistic effect between olive oil and eucalyptus oil.

16.6.1.3 Ceramic nanoparticles

Ceramic NPs represent one of the most commonly employed inorganic NPs for wound healing. These NPs are mostly known for their wound healing, tissue regeneration, and antibacterial properties (Urie et al., 2018). Nanohydroxyapatite and calcium triphosphate as ceramic NPs of-

UNCORRECTED PROOF

fer broad applications in drug delivery and wound healing processes. the sol–gel formulation method is generally used for the development of ceramic NPs. Furthermore, these NPs are extensively utilized in the development of tissue-engineered formulations. Various authors has revealed the potential of ceramic NPs, such as Deepthi and co-workers who described the use of ceramic-CS-based NPs for bone rejuvenation (Deepthi et al., 2016). When combined with CS, components such as hydroxyapatite, silicon dioxide, bioglass ceramic, titanium dioxide, and zirconium oxide formed nano-scaffolds that are very effective in regenerating bone. To cure bone abnormalities in traditional therapies, artificial materials were implanted surgically, although this had several negative side effects. Hence, ceramic nanoparticles are employed to clear the way for tissue regeneration to overcome these problems. A bioactive ceramics and bioresorbable polymer mixture creates an extracellular matrix for the healing of bone tissue.

16.6.2 Polymeric nanoparticles

In the current era, strategies for the treatment of chronic wounds have been developed to deliver drugs and biomolecules in bioresorbable polymeric NPs with controlled release, such as PLGA, alginate, gelatin, chitosan, PEG, and polycaprolactones. Polymeric NPs avoid frequent dosing, extend the therapeutic effectiveness, and provide controlled drug delivery in wound healing (Masood, 2016).

16.6.2.1 Synthetic

PLGA offers one of the most widely used synthetic polymers due to its biodegradability, biocompatibility, hydrophobic property, and for entrapping the growth factor in chronic wound therapy among all polymeric NPs. It offers sustained drug release through NPs because it absorbs less water and enhances the degradation time (Masood, 2016). Additionally, the breakdown of PLGA yields lactate, which promotes pro-COL factors, angiogenesis, and the recruitment of endothelial cells to the wound site. A combinational therapy of PLGA–curcumin NPs revealed a twofold higher potential in wound healing than PLGA and curcumin alone.

Polyurethane is utilized to develop the bioresorbable polyester known as polycaprolactone (PCL). It is well known for its controlled intracellular reabsorption mechanism and its cell-specific responsiveness. In contrast to various available synthetic polymers, it is simple to use and can

UNCORRECTED PROOF

form a variety of nanostructures, including scaffolds and micro- and nano-carriers (Guarino et al., 2002). The antibacterial, antimicrobial, and wound-healing properties of PCL have been illustrated in numerous investigations to be enhanced by their combination with any metal or metal-based NPs. One study conducted on a skin model using zinc NPs which were developed by electrospun polycaprolactone provided scar-free wound healing by enhancing fibroblast proliferation (Augustine et al., 2014).

16.6.2.2 Natural

Chitosan (CS) is available from the shells of crustaceans and is made up of N-acetyl-D-glucosamine and randomly dispersed D-glucosamine. CS offers numerous potential in wound-healing applications, such as biodegradability, biocompatibility, cellular binding capacity, wound healing, etc. (Li et al., 2012). The study performed by Piran and co-workers developed electrospun PCL nanoscaffolds loaded with chitosan. The effect of the CS NPs scaffold topography and drug release behavior on skin fibroblasts has been investigated (Piran et al., 2018). Another prominent natural polymer used in wound healing is alginate, which is found in the cell wall of brown algae and which possesses maximum scaffold capacity. A study by Liao and co-workers developed porous alginate hydrogels. These hydrogels contains PCL, PEG, and calcium gluconate crystals which are effectively deposited in the pores of microspheres. The data revealed that the prepared hydrogel effectively enhanced the growth of fibroblasts, which led to providing new areas for skin tissue engineering (Liao et al., 2018).

16.6.3 Hydrogels

Hydrogels are among the most prevalent wound-healing systems because they trap moisture at the wound surface, develop an optimum environment for healing, and keep the skin hydrated. They are easily formulated and also allow prolonged drug release. Chitosan, fibrin, hyaluronic acid, or synthetic polymer, either as cellulose compounds or poloxamers, can be used to make hydrogels. These hydrogels are able to create a cool and moist environment that promotes the wound-healing process as well as water vapor permeability and inhibiting microorganisms from entering the wound.

UNCORRECTED PROOF

A study performed by Khorasani and co-workers developed a CS-ZnO-PVA-based hydrogel which progressively enhanced the antibacterial properties without any cellular toxicity (Khorasani et al., 2018). Another study performed by Hsu and co-workers developed gel-based adipose-derived stem cell hydrogels for the treatment of wounds. This in vivo study revealed enhanced wound healing on both mouse and porcine skin models (Hsu et al., 2019).

16.6.4 Nanofibers

Nanofibers (NFs) are the key nanomaterial utilized for the wound-healing process. NFs have a diameter of 10–100 nm and a large specific surface area (Abrigo et al., 2014). They are formulated using the process of electrospinning technology, where various polymer solutions are processed into nanometric fibers using electric force. These fibers have the capability to create a porous network forming a mesh. Due to the tough network and higher surface area to volume ratio, NFs are suitable candidates to use as scaffolds. They can be synthesized from natural or synthetic polymers as well as carbon-based and semiconductor materials. These fibers are renowned for their use in biological sensing, wound dressing, drug delivery, and tissue engineering formulations along with regenerative drug therapies (Chen et al., 2017).

A study by Kandhasamy and co-workers developed a nanofiber scaffold using COL-coated ostholamide for wound treatment. The prepared formulation possessed excellent mechanical characteristic and antimicrobial property against *P. aeruginosa* and *S. aureus*. The prepared system offers controlled delivery of ostholamide and provides stability against enzymatic degradation. In another study, a PLGA-aloe vera gel-growth factor scaffold was formed by electrospinning technology. In vivo studies on a mice model showed excellent wound-healing properties by reducing the inflammation (Garcia-Orue et al., 2017).

16.7 Conclusion and future perspectives

In pharmaceutical and biomedical applications, bioresorbable polymers offer excellent potential. Bioresorbable polymers for wound healing must be mechanically strong, have good antibacterial activity, and have hemostatic, water vapor permeability, appropriate gas exchange as well as higher free radical scavenging properties. Such characteristics can en-

UNCORRECTED PROOF

hance the wound-healing process. Additionally, the dressing should be easy to remove after healing and should be nontoxic, biocompatible, nonallergic, bio-stable, and biodegradable. Natural and synthetic bioresorbable polymers offer their own advantages while treating wound. Many researchers and scientists have proved the capabilities of such polymers by encapsulating them in nanocomposites such as nanoparticles, nanocarriers, hydrogels, metal and metal oxide components, etc. for tissue regeneration, and healing of skin burns and wounds, particularly using in vitro models. Wound healing has attracted the attention of many researchers as it is difficult to treat chronic wounds. The market is constantly expanding, driven by the rise in the number of patients globally, requiring new tactics and materials. Polymer- and hydrogel-based dressings make up the majority of competitive technologies available today for advanced wound care. Advanced dressings typically serve a purpose beyond merely concealing and covering wounds. By using the bioactive qualities of polymers, it is feasible to speed up tissue remodeling and regeneration, improving skin conditions while minimizing the appearance or size of any associated scars.

Despite the broad variety of solutions already in the market, bioresorbable dressings have a low impact on the healing of complex and chronic wounds, although they remain essential components of acute wound care. Recently, enormous progress has been made in our understanding of the molecular mechanisms underlying wound healing, and we may now use this expertise to create novel therapeutic strategies for nonhealing wounds. Also, employing natural resources can effectively overcome these issues. Tissue engineering techniques use 3D hybrid scaffolds which are both synthetic and natural that interact with human cells effectively. The possible advantages of this strategy include the capacity to increase the in vivo properties which enhance bone formation, reducing donor site morbidity, shortening the surgical time, and decreasing the technical difficulty of the repair. A 3D reconstruction will significantly reduce the amount of time needed for healing. Additionally, it ensures optimal contact between the graft and the recipient site for better integration. Another benefit is increased permeability with particular hybrid materials, which is essential for tissue remodelling and replacement. As a result, theblood can easily flow through the graft's internal chambers without any resistance Hence, because of such tactics, the healing process is significantly enhanced because of cell attachments.

Preface *xxv*

SECTION 1 Fundamentals, processing, and modelling

1. Introduction to bioresorbable polymers: Types and biomedical applications **3**

Deepak Verma, Manunya Okhawilai, Kheng Lim Goh, Mohit Sharma, Pooria Pasbakhsh and Seeram Ramakrishna

1.1 Introduction 3
1.2 Bioresorbable polymers and their classifications: An overview 5
1.3 Polymer degradation: An overview 10
1.4 Bioresorbable polymer resorption process 11
1.5 Bioresorbable polymers and their biomedical applications 14
1.6 Conclusion 17
References 18

2. Bioresorbable polymers and their composites for biomedical applications **23**

Oludaisi Adekomaya and Thokozani Majozi

2.1 Introduction 23
2.2 Salient properties of bioresorbable materials for biomedical application 28
2.3 Performance of bioresorbable materials in medical interventions 33
2.4 Conclusion 37
Acknowledgments 39
References 39

3. Processing techniques for bioresorbable-based composites for medical device applications **41**

Nadda Chiaoprakobkij and Manunya Okhawilai

3.1 2D structure 41
3.2 3D structure 48
3.3 Micro-molding 55
3.4 Particulate structures 57

3.5 Conclusion and outlook 59
References 59

4. PCL-based composites and their utilizations in the medical sector 63

Deepak Gupta, Vaishally Dogra, Deepak Verma, Arun Kumar Chaudhary and Maneesh Tewari

4.1 Introduction to biopolymer composites 63
4.2 Development and synthesis of PCL 64
4.3 Advantages of PCL-based composites in the medical sector 67
4.4 Applications of PCL in different medical sectors 68
4.5 Challenges and future of PCL in the medical sector 77
4.6 Conclusion 78
References 78

5. Processing of PLA/PLLA-based composites for medical device applications 85

Deepak Gupta, Vaishally Dogra, Deepak Verma, Arun Kumar Chaudhary and Maneesh Tewari

5.1 Introduction 85
5.2 The chemical structure and synthesis of PLA/PLLA polymers 87
5.3 The physical and thermal characteristics of PLA/PLLA polymers 88
5.4 PLA/PLLA-based composites fabrication methods 90
5.5 Biocompatibility and biodegradability of PLA/PLLA composites 92
5.6 Applications of PLA/PLLA composites in the medical sector 92
5.7 Future perspectives 101
5.8 Conclusion 101
References 101

6. PHA/PHB/PHBV-based composites: development and biomedical applications 107

Ivana Cesarino, Ivan Moroz, Afonso Freitas Carbonera, Guilherme de Oliveira Martins, Luís Guilherme Leite Fernandes and Alcides Lopes Leao

6.1 Introduction 107
6.2 Polyhydroxyalkanoates (PHA) 108
6.3 Polyhydroxybutyrate (PHB) 112
6.4 Poly(hydroxybutyrate-co-hydroxyvalerate) (PHBV) 115
6.5 Conclusion 120
References 120

7. Synthesis and applications of bioresorbable polymers for tissue engineering scaffolds 125

Emenike George Okonkwo, Jesus Romo-Rico, Chinemerem Jerry Ozoude and Kingsley Job Obasi

7.1 Introduction 125
7.2 Synthesis of bioresorbable polymers 126
7.3 Applications of bioresorbable tissue scaffold 135
7.4 Future trends 138
7.5 Conclusion 139
References 140

8. Gelation and fabrication of bioresorbable-based hydrogels for drug-release applications 147

Chuanchom Aumnate, Chaimongkol Saengow and Manunya Okhawilai

8.1 Introduction 147
8.2 Cross-linking of hydrogels 148
8.3 Hydrogel fabrication 157
8.4 Conclusion 165
References 166

9. Molecular modeling of polymers for efficient drug-carrier applications 169

Rosaline Mishra, Dinesh Puri, Radha Goel, Praveen Kumar Gaur, Prasoon Kumar Saxena, Niharika Lal and Kanak Lata

9.1 Introduction 169
9.2 Methods for molecular simulation for designing polymers 171
9.3 Applications of the polymer-based smart nanocarriers 175
9.4 Conclusion 188
References 189
Further reading 194

10. Electrospinning technique: A potential method to develop bioresorbable-based medical devices 197

Senthilkumar Nangan, Natesan Thirumalaivasan and Ramasubburayan Ramasamy

10.1 Introduction 197
10.2 Fundamentals of electrospinning 198

10.3 Application of electrospun nanofiber membranes in medical protective equipment 205
10.4 Conclusion 209
References 210

11. Modeling of drug release from a bioresorbable polymer matrix system 213

Mohd Yasir, Dinesh Puri, Manikandan Arumugam, Wondesen G. Gobena, Mohammed Hussien Wondabo, S. Roshan and K.M. Noorulla

11.1 Introduction 213
11.2 Biodegradable/bioresorbable polymers 214
11.3 Factors affecting drug release from polymers 216
11.4 Diffusion law 217
11.5 Fundamentals of drug-release kinetics 219
11.6 Need for and objectives of mathematical models 221
11.7 Release kinetic modeling 222
11.8 How to select the best-fitting model 242
11.9 Conclusion and future perspectives 248
List of abbreviations 249
References 250

SECTION 2 Biomedical applications

12. Bioresorbable polymers: A prospective utilization as an implant 259

Shuai Chen, K. M. Faridul Hasan and Xiaoyi Liu

12.1 Introduction 259
12.2 Characteristics of bioabsorbable polymers as implants 262
12.3 Application of bioabsorbable polymers 264
12.4 Conclusion 272
References 272

13. Polymeric (PLGA-based) nanocomposites for application in drug delivery: Current state of the art and forthcoming perspectives 277

Sanket Kumar, Supriya Singh, Sheikh Shahnawaz Quadir, Garima Joshi, Mangilal Chouhan, Dinesh Puri and Deepak Choudhary

13.1 Introduction 277
13.2 PLGA properties 280

13.3 PLGA nanocomposite carriers: fabrication techniques 284
13.4 Applications of PLGA nanocomposites 293
13.5 Conclusions and future prospects 312
Abbreviations 313
References 314

14. Bioresorbable polymers: Challenges and opportunities for development and applications of medical devices 325

Pornnapa Kasemsiri, Kaewta Jetsrisuparb, Jesper T.N. Knijnenburg and Manunya Okhawilai

14.1 Introduction 325
14.2 Bioresorbable polymers for drug-delivery systems 326
14.3 Bioresorbable polymers for medical devices 330
14.4 Bioresorbable polymers for tissue engineering 330
14.5 Conclusions 346
References 347

15. Bioresorbable polymers for wound healing 353

Sheikh Shahnawaz Quadir, Dinesh Puri, Garima Joshi, Deepak Choudhary, Sanket Kumar, Monika Singh and Shalini K. Sawhney

15.1 Introduction 353
15.2 Wound-healing process 355
15.3 Factors affecting wound healing 356
15.4 Properties of bioresorbable polymers 363
15.5 Bioresorbable polymers for wound healing 364
15.6 Nanocomposites for wound healing 372
15.7 Conclusion and future perspectives 377
References 378

16. Bioresorbable polymers/HNT blend composite wound dressings 385

Deepak Gupta, Arun Kumar Chaudhary, Deepak Verma and Mohit Sharma

16.1 Introduction to bioresorbable polymers 385
16.2 Classifications of bioresorbable polymers 389
16.3 Halloysite nanotubes 391

16.4 Bioresorbable polymer-based HNT composites 393
16.5 Mechanical properties of HNT-reinforced polymer blends 394
16.6 Antibacterial activity of HNT—polymer blends 395
16.7 Drug-delivery capacity of HNT—polymer blends 397
16.8 Wound dressings based on HNT—polymer blends 405
16.9 Challenges and limitations of HNT—polymer blends 412
16.10 Future prospects of HNT—polymer blends in biomedical applications 413
16.11 Conclusion 414
References 414

17. Biobehavioral structure, elastic, optical, and thermoluminescence properties of $Al_xCa_{y-x}Nd_{01}P_{70}$ bioglasses 421

Ravi Kumar Guntu

17.1 Introduction 421
17.2 Methods and measurements 422
17.3 Results and discussion 423
17.4 Summary and conclusion 439
References 439

18. A prospective utilization of biodegradable polymers for controlled drug-delivery applications 443

Dinesh Puri, Deepak Choudhary, Mohd Yasir, Rosaline Mishra, Sanjay Sharma, Radha Goel and Praveen Kumar Gaur

18.1 Introduction 443
18.2 Classification of biodegradable polymers for CDDS 445
18.3 Application of biodegradable polymers in drug delivery 451
18.4 Mechanism involved in controlled release through polymers 452
18.5 Release kinetic 457
18.6 Examples of commercially available biodegradable polymer base products 457
18.7 Conclusion 460
References 460

19. Bioresorbable polymer-based sensors for medical applications 469

Thirumalaivasan Natesan, Senthilkumar Nangan and Ramasubburayan Ramasamy

19.1 Introduction 469
19.2 The essential principles of biodegradable polymers and their pertinent physiochemical attributes for medical utilization 470
19.3 A comprehensive review of current biodegradable sensing devices, classified according to their healthcare functionalities such as cardiac surveillance, glycemic level monitoring, and ophthalmic pressure assessment 473
19.4 An overview of the fabrication techniques for bioresorbable polymer-based sensors 476
19.5 Physical sensors 481
19.6 Chemical sensors 486
19.7 Conclusion 487
References 488

About the editors

Deepak Verma

Deepak Verma is currently working as a Research Assistant in the Department of Nanoscience and Technology, Graduate School, Chulalongkorn University, Bangkok, Thailand. He also served as an Assistant Professor, in the Department of Mechanical Engineering, at Graphic Era Hill University, Dehradun, India. He received his MTech from the College of Technology, GBPUA&T Pantnagar, India. He has over 13 year of teaching and research experience in developing advanced materials such as electrospun membranes for biomedical applications and natural fiber-based polymer composites or green composites for advanced and sustainable applications. Deepak Verma was the editor of *Biomass, Biopolymer-Based Materials, and Bioenergy*, Woodhead Publishing House, Elsevier; and *Sustainable Biopolymer Composites*, Woodhead Publishing House, Elsevier. He is currently working in the area of medical devices and their applications. Overall, he has published more than 35 book chapters with Elsevier and other publishers, and more than 25 international journal papers in reputed journals with high impact factors.

Manunya Okhawilai

Dr. Manunya Okhawilai, Head of Materials and Advanced Polymer Technology Laboratory, is a Research Professor at Metallurgy and Materials Science Research Institute, Chulalongkorn University, Bangkok, Thailand. She effectively attained her doctoral degree with a dedicated emphasis on the field of Chemical Engineering specialization. She is particularly interested in polymer blends and polymer composites. Her main research areas are focusing on quasi and solid-state polymer electrolyte and separator for metal ion batteries and flow batteries as well as electrode for hydrogen production and electricity. Furthermore, she has dedicated her research efforts to the development of bioactive packaging using biopolymers and smart strain sensors. She has published book chapters and more than 50 research articles in reputed peer reviewed journals with high impact factors.

Kheng Lim Goh

Dr. Kheng Lim Goh is an Associate Professor and Reader in Mechanics of Composite Materials and Director of Research at Newcastle University in Singapore. He is a Fellow of the Institute of Mechanical Engineers

(FIMechE) and Fellow of the Institute of Physics (FInstP), Chartered Engineer (CEng) and Chartered Physicist (CPhys). He has a long-standing interest in composite materials. His research aims to understand the physical properties of natural and synthetic composite materials and to use this understanding to engineer nanocomposite materials and repair damaged composite materials. Dr. Goh has authored and coauthored over 120 papers in peer-reviewed journals, edited 3 books, and delivered plenary/keynote lectures at several international conferences. Dr. Goh is the author of the book entitled *Discontinuous-Fibre Reinforced Composites: Fundamentals of Stress Transfer and Fracture Mechanics*, published in 2017. Before joining Newcastle University, Dr. Goh held the post of Assistant Professor in Bioengineering at Nanyang Technological University and Senior Lecturer in Mechanical Engineering at Monash University. Dr. Goh received his BSc (Physics, Honors) degree from the National University of Singapore, MSc degree (National University of Singapore) in bioengineering, MSc degree (Aberdeen University) in Medical Physics, followed by Ph.D. (at the University of Aberdeen scholarship) in Biomedical Physics and Bioengineering.

Seeram Ramakrishna

Professor Seeram Ramakrishna is a world-renowned scholar of materials and cross-fields at the National University of Singapore (NUS). He is named among the World's Most Influential Minds (Thomson Reuters); and Top 1% Highly Cited Researchers in the world (Clarivate Analytics). Ioannidis/Stanford University C-score ranks him among top six impactful researchers of the world in materials, biomedical engineering, and enabling and strategic technologies. His publications to date have an H-index of 182 and over 165,152 citations. He is advocating sustainable | living | intelligent biomedical materials. He is the Biomaterials Section Editor of the Elsevier journal *Current Research* in Biomedical Engineering (https://www.sciencedirect.com/journal/current-opinion-in-biomedical-engineering/about/editorial-board), and editorial board member of the Elsevier journal *Biomaterials Advances*. He is an elected Fellow of the American Association for Advancement of Science (AAAS); ASM International; ASME; AIMBE, USA; and UK Royal Academy of Engineering (FREng). He is an elected Fellow of the International Union of Societies of Biomaterials Science and Engineering (*FBSE*).

Pooria Pasbakhsh

Dr. Pooria Pasbakhsh has been an Associate Professor in the School of Engineering at Monash University Malaysia. His research interests include polyurea, clay nanoparticles, self-healing materials, polymer nanocomposites, material characterization, and industrial applications of polymer composites. Dr. Pasbakhsh has published over 100 journal or conference papers, edited/coedited four books, and participated as an invited speaker or chair at several conferences. He has also participated in numerous collaborations aiming to integrate industry needs into academic research, and to support composite and nanomaterial industry applications. Dr. Pasbakhsh is one of the editorial boards of the journal of *Applied Clay Science* and he has been among the Top 2% scientists (Stanford List) from 2020 to 2022.

Mohit Sharma

Dr. Mohit Sharma is working as a Principal Scientist at Advanced Composite Engineering Group at the Institute of Materials Research and Engineering (IMRE), a leading research institute from Singapore's Agency for Science, Technology and Research (A*STAR). His current assignments are focused on lead technology acquisition for advanced composites innovations. He is building team competencies by leading key research activities in liaison with industries, which aim to create social impact and value capture. He is associated with Singapore graduate academy to nurture foreign talent and Ph.D. student training. His focused research includes sustainable and scalable composite material technologies, structural health monitoring, specialty polymers, bioresorbable and bio-compatible composites, composites recycling, and materials for harsh utilities and green initiatives.

Preface

Bioresorbable materials have been noticed in the last 10 years because of their suitable properties for biomedical applications. Dozens of materials are available, termed bioresorbable, but very few of them are recognized for medical device applications. The bioresorbable materials suitable for medical devices are glycolide-lactide polymers and copolymers, polycaprolactone, polydioxanone, and poly trimethylene carbonate. The applications of bioresorbable materials include but not limited to surgical sutures, orthopedic pins, screws, rods and plates, cardiovascular stents, etc. This book is divided into two parts. Part I is Fundamentals, Processing, and Modeling and Part II is Biomedical Applications. Part I describes an introduction to bioresorbable polymers and their utilizations as tissue scaffolds, drug delivery, implants, and molecular modeling. In Part II, bioresorbable-based polymer composites and their biomedical applications are described.

This book also focuses on the characterization techniques such as SEM, AFM, FTIR, etc. This book also focuses on the variety of biomaterials, their processing, and their usefulness in biomedical sectors. Also, we tried to include some chapters related to bioresorbable polymer processing and its properties. Moreover, this book should represent an indispensable resource for the growing number of scientists, engineers, physicists, and chemists interested in the preparation and applications of bio-based composites and nanocomposites for different final applications; it would be useful for those interested in finding new ideas for potential applications such as medical devices and for industrial scientists active in formulation, fabrication, and repairing of polymer products based on renewable resources.

This book will not be limited to developing polymer composites or nanocomposites. As we can notice from the other available books (listed above), these books only focus on bioresorbable materials and their utilization in the biomedical field. They were not discussing the other useful applications of the bioresorbable polymer-based composites, such as drug release, implants, wound healing, and wound dressing materials. The proposed book will focus on the vast domain of bioresorbable polymers, such as synthetic and biopolymers. The current theme will discuss the drug release mechanism/analysis of the nanomedicine blended with bioresorbable polymers. We will also discuss applications like biosensor

implants and their medical applications as medical devices, drug release, medical textiles, implants, and dressing materials. So, we can say that this book is the blending of the development/processing of the different types (bioresorbable polymers) of composite materials, their analysis (characterization and fracture), modeling of the composites, and biosensors, frequently utilized in the medical sectors.

This book also addresses the sustainable composites development process, including biocompatibility, tissue repair, scaffold development, recyclability, and systematic procedures and methods. It helps as a pertinent reference for readers, undergraduate and postgraduate students, doctors, academicians, researchers, engineers, and scientists interested in this imperative research area. This book's content will be divided into various chapters addressing the key concerns and interpretations. The researchers/readers will benefit by following the content of the different modules and chapters written by expert scientists of the related research areas. They are skillful individuals who own these technologies and/or suggest viable solutions for key associated problems. So, this book will be useful for graduate and postgraduate research scholars to identify the current/existing problems related to implants, wound dressing materials, bone graft materials, dental materials, and suggested tissue repairing and healing methods. A futuristic conclusion will be strategies for adopting novel nanocomposite processing, biocompatibility, ease of production, etc.

We appreciate all the global contributors' commitment and acceptance of chapter invitations, knowledge sharing, and integration of their research skills for writing the chapters and following editorial inputs to make this book project successful. We also thank Woodhead Publishing house and the Elsevier team for their generous cooperation at every book production stage.

CHAPTER 1

Introduction to bioresorbable polymers: Types and biomedical applications

Deepak Verma[1,2], Manunya Okhawilai[3,4], Kheng Lim Goh[5,6], Mohit Sharma[7], Pooria Pasbakhsh[8] and Seeram Ramakrishna[9]

1.1 Introduction

This book is about biomaterials for biomedical applications. The first and foremost requirement of a biomaterial or bioresorbable material is that it should be nontoxic, biocompatible, and can be used for specific applications. The degradation of the polymer in the body is through cellular activity under the biological environment. Enzymes and microbes dominate the biodegradation process, remodeling the human body's degraded part (Ottenbright and Scott, 1992). Not all degradable materials need to be absorbed into the body; it may depend on the transformative step that alters the material's physiological properties/conditions, leading to the transformation/disappearance of the material/implant (Tormala et al., 1986). The most significant condition for an implant material is that it should be biocompatible and nontoxic, and exhibit good physical structure and biomechanical properties (Pulapura and Kohn, 1992). Based on this, different generations of materials have been developed, e.g., first-generation and second-generation materials. The first-generation materials were developed explicitly for good mechanical strength and relatively acceptable "bio-inertness." However, it is difficult for any material to have total

inertness, therefore, based on this, second-generation materials have been developed (Pertici, 2017). These materials consider and elicit the specific reactions and responses from the biomaterials and particular cells within the body. Metals and their alloys, ceramics, synthetic polymers, and composites are some other materials primarily utilized for implants because of their excellent mechanical properties, such as toughness, ductility, and high strength. However, the metallic-based implant must be removed after its intended use, requiring second surgery (Agrawal and Ray, 2001).

Conversely, ceramics and glass can serve as substitutes for bones, yet their fragility renders them unsuitable for weight-bearing functions. Polymers, while displaying inferior attributes in comparison to metals, ceramics, and glass, find effective use in bone replacement and fixation due to their ease of manipulation and compatibility with the body (Hench et al., 1971). Polymers should be reinforced with metals, nanoparticles, ceramics, or glasses to attain the specific properties of specific applications. Bioresorbable polymers do not create a corrosion effect as metallic implants may do (Pertici, 2017). Polylactide, polyglycolide, and their copolymers are bioresorbable polymers frequently utilized as surgical implants because of their suitability and chemical stability (Chatterjee et al., 2019). Bioresorbable polymers are also proposed for stent manufacturing and applications. Also, synthetic or natural bioresorbable polymers have found their applications in tissue engineering, regeneration, and tissue scaffolding (Tormala et al., 1986).

Bioresorbable materials have diverse applications in biomedical areas, i.e., implants and suture applications and wearable electronic devices for monitoring health conditions. Microelectromechanical systems-based implants are some examples developed using bioresorbable polymers for real-time monitoring of body parameters, such as temperature, pressure, and cardiovascular activities (Chen et al., 2010). Another significant application of bioresorbable-based implants is drug delivery, associated with the required dosages to fully treat the patient (Millard and Shepherd, 2007). These implant devices themselves select the drug in required/prescribed dosages and deliver it by simulating the nervous system in the body (Park et al., 2015). There may be a problem of infection caused by permanent implants because of the formation of biofilm on the device (Hall-Stoodley et al., 2004). This may result in resurgery of the affected site to remove the infected device, causing further major complications (Kuhn et al., 2012). This problem creates a financial and physical burden for the patient. However, material advancement develops a new class of material with a meager chance of biofilm generation causing infections as they dissolve in

the body after a specific or stipulated timeframe. Also, the patient does not require a second surgery to remove the infected implant device (Boutry et al., 2019; Shin et al., 2019). The potential application of bioresorbable polymers is considered for orthopedic implants because of their significant mechanical properties. Also, due to their bioresorbability, they showing superior application as cardiac stents (Oosterbeek et al., 2022). Additive manufacturing or 3D printing provides more accuracy in developing bioresorbable implants for biomedical applications (Culbreath et al., 2020). This chapter discusses bioresorbable polymers and their classifications and degradation mechanics. Various factors that affect the bioresorption process and the influence of porosity on the bioresorbability are discussed. Clinical applications of bioresorbable polymers and their composites are also explored.

1.2 Bioresorbable polymers and their classifications: An overview

Bioresorbable polymers undergo degradation within the physiological milieu upon fulfillment of their intended functional role (Petersen et al., 2020). Compared to the other conventional materials (for implants), they do not require a second surgery to remove the implant. Bioresorbable polymers have shown excellent applications in the biomedical sectors, specifically drug delivery and implants. The following is a general classification of the bioresorbable materials.

1.2.1 Natural bioresorbable materials

Various natural bioresorbable polymers encompass chitin and chitosan, alginates, and cellulose, as discussed here.

1.2.1.1 Chitin and chitosan

Chitin and chitosan are polysaccharides that are abundantly available worldwide. Chitin is commonly found in crustacean shells/skeletons. There are three general classifications of chitin: α-chitin, β-chitin, and γ-chitin" (Muzzarelli, 1977). It is the most produced polysaccharide worldwide after cellulose. Chitin is mostly used in biomedical applications, particularly wound-healing applications. It shows excellent wound-healing properties. Numerous researches have been carried out in utilizing chitin for wound-healing applications in hydrogel films, sponges, nanofibers, etc. Chitin consists of acetylglucosamine groups, where the acetyl group is connected

with each glucosamine molecule. Chitosan is derived from chitin. The deacetylation of chitin provides chitosan. Chitosan consists of amino groups and provides polycationic behavior to the polymer (Rinaudo, 2006). Chitosan, a mucopolysaccharide, exhibits structural properties resembling those of glycosaminoglycans. Chitosan is found in numerous varieties with different deacetylation degrees and molecular weights (Lehr et al., 1992). Chitosan can be prepared by decalcifying crustacean shells in dilute HCl, leading to deproteination using dilute NaOH at boiling point. After that, the deacetylation of chitin takes place in concentrated NaOH solution at boiling point. This deacetylation is repeated until biomedical-grade chitosan is obtained. Pure chitosan for pharma purposes can be obtained at 90%–95% deacetylation (Jayakumar et al., 2007).

Chitosan and its derivatives are mostly used in biomedical applications, specifically in drug delivery, hemostatic agents, wound dressings/healing, surgical sutures, etc. Chitosan is easily available and possesses biodegradable characteristics (Chandy and Sharma, 1990). It also exhibits low toxicity and is considered to be biocompatible. Chitosan also shows antibacterial properties, which makes it a significant material to be utilized for biomedical applications. Fig. 1.1 shows the structures of chitin and chitosan.

1.2.1.2 Alginates

Alginates represent a binary copolymer comprising L-guluronic acid (G) and D-mannuronic acid (M). Alginate is primarily found in brown seaweed, with calcium, sodium, magnesium, and potassium salts present in the kelp wall of the cells. These two monomers (G and M) are connected with each other and provide the physical and chemical properties of the alginates. Two bacterial species, *Azotobacter* and *Pseudomonas*, are also used for synthesizing alginates; however, at an industrial level, alginates are the

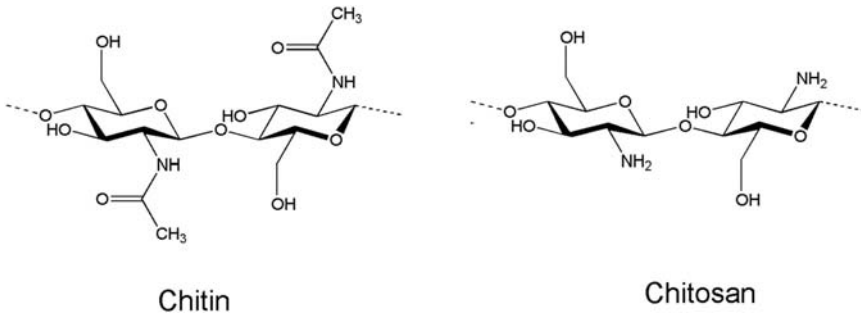

Figure 1.1 Chitin and chitosan. *(Reproduced with permission from Hahn et al. (2020).)*

extracted from brown algae. The quality of alginates primarily depends upon the molecular weight, and M and G proportion/ratios. The biomedical applications of alginates are particularly focused on wound dressings. Calcium alginates are natural hemostats and can be used for treating bleeding wounds (Paul and Sharma, 2008). The alginate's main phenomenon is that it transforms into a gel, and when it is applied to wounds and during removal/changing of dressings, the patient does not experience any pain. The moisture environment of alginates helps reepithelization and fast granulation, which are required for rapid wound healing. Alginates have good absorptivity, gelling ability, hemostat quality, and biocompatibility, making them an effective option for wound dressing (Ikarashi et al., 1992) (Fig. 1.2).

1.2.1.3 Cellulose

Cellulose, a complex polysaccharide obtained from β-glucose and comprised of 1,4-glycosidic bonds, is abundantly available in plants. Within plant cell walls, cellulose is a structural material primarily found in trees. Cellulose is commercially produced using a chemical pulping process. Wood and cotton are the main sources of commercial cellulose production, comprising around 90%–99% and 40%–50% cellulose, respectively (Hon, 1996). Cellulose is a straight-chain polymer whose microfibrils consist of multiple –OH groups connected via hydrogen bonds with glucose, resulting in an increase in tensile strength (Kim et al., 2006). There are numerous biomedical applications of cellulose, e.g., drug delivery, wound dressings, dialysis membranes, etc. Cellulose's good mechanical properties and permeability make it suitable for dialysis applications. It has been observed that cellulose has poor hemocompatibility, which can be improved by applying some modification techniques. Because of strong inter- and intramolecular interactions, cellulose has been found to be insoluble in water (Kai et al., 2000). Chemical etherification and

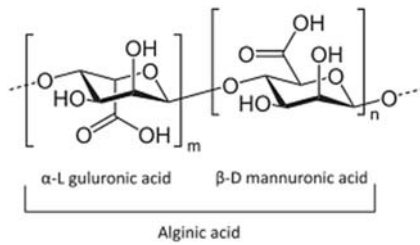

Figure 1.2 Alginate structure. *(Reproduced with permission from Liang et al. (2015).)*

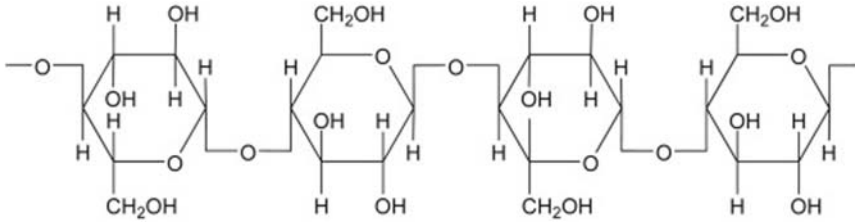

Figure 1.3 Cellulose structure. *(Reproduced with permission from Gilbert (2017).)*

esterification resolve its insolubility problem with water. Carboxymethyl cellulose has very good biomedical applications (Paul and Sharma, 2008) (Fig. 1.3).

1.2.2 Synthetic bioresorbable polymers

Synthetic biopolymers play a significant role in biomedical applications. The advantage of utilizing synthetic biopolymers is that they allow for better control of the properties of these polymers, such as molecular weight, mechanical, and degradation properties. One can develop and select the desired polymer for biomedical applications based on the specific requirements.

The following are some examples of synthetic biopolymers.

1.2.2.1 Polyvinyl alcohol (PVA)

The hydrolysis of polyvinyl acetate yields polyvinyl alcohol. The degree of polymerization and hydrolysis decides the physical properties of the polyvinyl alcohol (Roberts and Martens, 2016). Hydrolysis results in stronger inter- and intramolecular hydrogen bonds because of repeated hydroxyl groups (Chaouat et al., 2008). PVA exhibits higher water content, solubility, biocompatibility, and elasticity, and is mostly recommended for biomedical and pharmaceutical applications. Because of the numerous hydroxyl groups present, PVA macromers can be easily modified. Different groups, such as methacrylates, aldehydes, hydrazides, etc., can modify PVA, etc., which helps with in situ gelation (Lim et al., 2013). This means that different functional and cross-linking groups can be attached to the PVA, which helps further cross-linking and degradation. PVA is most suitable and has found its application for cell encapsulation because of its lower adhering properties with proteins (Dini et al., 2005). Because of biocompatibility and low toxicity, PVA has different applications, such as in contact lenses and cartilage replacement (Singh et al., 2020).

1.2.2.2 Polyethylene glycol (PEG)

Polyethylene glycol, also known as polyethylene oxide, is one of the most versatile polymers utilized for pharmaceutical and biomedical applications (Roberts and Martens, 2016). The major application of PEG is in hydrogel development because of its quick solubility in water and solvents (organic). The US FDA also has approved PEG because of its nontoxicity and less adhesion to protein, which is necessary for biomedical applications (Peppas et al., 2006). Thiols and methacrylate functional groups can easily modify PEG (Fairbanks et al., 2009; Gould and Anseth, 2016). If the molecular weight of the ethylene oxide macromolecules is less than 20,000 g/mol, then it is called polyethylene glycol. However, if the molecular weight is higher than 20,000 g/mol, then it is known as polyethylene oxide (Lee et al., 2008). Because of the hydrophilic nature of PEG, it is effectively utilized in medicine and therapeutic applications (Kucharska, 2022). The major applications of PEG, because of its biocompatibility, are cosmetics, pharma, tissue engineering, drug delivery, etc. (Aied et al., 2018).

1.2.2.3 Polylactic acid (PLA)

Polylactic acid is a biodegradable polymer/plastic derived from lactic acid (Singh et al., 2020). Lactic acid is a source found in starch, sugar cane, and cassava starch, respectively. Lactic acid is mainly derived from fermentation. Also, PLA is derived from isomers like L-lactide, D-lactide, and DL-lactide, showing different forms like PLLA, PDLA, and PDLLA. Of these classes, PLLA and PDLA are semicrystalline, and PDLLA is amorphous. Two processes, polycondensation and ring opening of lactic acid, are used to obtain PLA. The difference between these processes is the molecular weights. Polycondensation of lactic acid gives lower-molecular-weight PLA; however, ring opening of lactic acid gives higher-molecular-weight PLA (Auras et al., 2022). PLA exhibits excellent biocompatibility, mechanical properties, and low toxicity (Laoutid et al., 2018). PLA has low biodegradability, which may be an issue for some biomedical applications such as tissue regeneration (after implantation) (Lett et al., 2020). The PLA surface is hydrophobic, which can also sometimes limit its applications for biomedical purposes. This can be avoided or limited by blending it with another biopolymer, such as PEG, which helps to make its surface hydrophilic (Hendrick and Frey, 2014).

1.2.2.4 Polycaprolactone (PCL)

Polycaprolactone is a synthetic bioresorbable polymer that is derived by a ring-opening polymerization process of ε-caprolactone. PCL has a melting point of 59–64°C (Middleton and Tipton, 2000) and it has superior mechanical properties, such as tensile modulus and strength of 400 and 16 MPa, respectively (Daniels et al., 1990). Its lower melting temperature makes it suitable for diverse applications, and the mechanical properties of PCL can be easily improved by incorporating some nanofillers or nanoparticles. Because of the hydrophobic nature of PCL, it has durability also, i.e., it has the longest degradation time, and this polymer can be used for applications where a long degradation time of the biopolymer is of primary importance (Mano et al., 2004). Bone tissue engineering is the major application for efficiently utilizing this polymer (Cameron and Kamvari-Moghaddam, 2012).

1.3 Polymer degradation: An overview

There are two key processes governing polymer degradation (Pan, 2015), namely chemical hydrolysis and organism degradation (Casalini et al., 2019). In the first classification, water comes into contact with the polymer matrix. It interacts with the hydrolysable bonds and breaks the long chain of the polymer into small oligomers, which are water-soluble, that can easily diffuse through the polymer matrix leading to degradation of the polymer. In the second classification, organs remove the degraded products by themselves, which entirely depends upon the type of material used. Examples of polyanhydride and polylactic acids utilization as implants can help us understand this. Hydrolysis of polyanhydride results in aromatic monomers which are discharged without any metabolic transformations (Katti et al., 2002); however, the particles of PLA are transformed into monomers by the enzymes and then metabolized by following the citric acid cycle (Pan, 2015).

However, if the characteristic time of penetration (water) is less than the hydrolysis time, it may result in bulk degradation. In contrast, if the hydrolysis time is longer than the characteristic time, it may result in surface degradation. This means the surface is degraded without affecting the bulk of the matrix (Burkersroda et al., 2002). Also, there is a difference between degradation and erosion. Considering the erosion of the polymer matrix, there are two different types of erosion possible, i.e., bulk erosion and surface erosion. Diffusion of the mass (monomers and oligomers) toward

the neighboring environment, which causes mass loss, is known as erosion. Drug delivery/release can be directly linked with polymer erosion (Göpferich and Langer, 1995; Göpferich, 1996).

Factors affecting the degradation rates are matrix composition, pH, thickness, molecular weight, crystal structure, and compound addition (Alexis, 2005).

Matrix composition generally affects the level of the hydrophilic behavior of polymers. If the level is high, then it is more prone to degradation.

pH level is also a deciding factor for polymer degradation. It is also true that the rate of degradation may differ in acidic and basic environments. Degradation causes a decrease in pH level (Alexis, 2005).

Thickness is another factor that determines the degradation rate. If the characteristic length exceeds the critical value it may result in surface degradation (Burkersroda et al., 2002).

Increasing *molecular weight* causes a decrease in degradation rate. A high molecular weight may result in low swellability of the polymer, ultimately resulting in low or less degradation of the polymer (Li, 1999; Alexis, 2005).

The *crystalline structure* level affects the polymer degradation. Amorphous polymers exhibit higher degradation rates than crystalline ones (Alexis, 2005).

Compound addition also affects degradation rates. In the case of acidic compounds, degradation follows hydrolysis, however, the basic compounds cause degradation through base catalysts (Elkharraz et al., 2006).

1.4 Bioresorbable polymer resorption process

The resorption process is complicated. In this process, the cells use the endocytosis process to devour the particulate and macromolecules. The cell plasma membrane completely covers the particulate matter, and compresses and develops a vesicle enclosed by the cell cytoplasm. The endocytosis process is better understood by phagocytosis that devours larger particulate materials. Two phagocytosis cells, macrophages and neutrophiles, are present in the body that not only help restrict the interactions of microorganisms but also consume damaged cells. Antibodies recognize the degradable implant's extraneous material and initiate phagocytic activity. The fusion of lysosomes with the phagocytic vesicle activates the degradation (particulate) by following through various oxidative and hydrolytic enzymes, speeding up the material breakdown. The bioresorption process is observed intracellularly; however, distribution of the enzymatic protein is

provided extracellularly, helping to degrade the degradable implants, if any. The phagocytosis process is effective on degradable substances. Hydrolytic activity also helps in the degradation process as it forms a large number of pores and voids through which enzymes enter and initiate catalytic degradation (Burg and Orr, 2008; Buchanan, 2008).

1.4.1 In vitro methods of bioresorbability evaluation

Bioresorbable polymers exhibit numerous applications in biomedical fields such as tissue repair/regeneration, drug delivery, surgery, etc. Aliphatic polyesters are mainly degraded by hydrolytic degradation, consisting of a complex physicochemical phenomenon evaluated using different in-vitro and in-vivo methods. The following section describes the bioresorbability evaluation of the bioresorbable polymers.

1.4.1.1 Physico-chemical methods

Various physicochemical test methods are used to evaluate the bioresorbability of polymers. These methods are as follows.

- Environmental scanning electron microscope (ESEM):

  The changes in the surface morphology of degraded polymers are identified/evaluated using the ESEM technique. The ESEM technique provides natural images. In this method, it is not necessary to apply a coating and high vacuum to obtain the specimen's morphology.
- SEC (size-exclusion chromatography):

  During degradation, this method observes changes in the average molecular weight, average number molecular weight, and molecular weight distribution of the polymer. Polymer chain cleavage results in a reduction in molecular weight. On the other hand, a change in molecular weight distribution is observed under rapid internal degradation, degradation-induced crystallization, and preferential amorphous degradation.
- XRD (X-ray diffraction):

  This is another method for evaluating the bioresorbability of polymers. The morphology of the polymers, such as amorphous or semicrystalline, plays a primary role during the degradation process. The XRD technique is used to observe changes in the crystalline structure of the polymer during the degradation process.
- DSC (differential scanning calorimetry)

  This is another method for evaluating the morphology of polymers, as with XRD. In this method, two scans of 10°C/min are performed.

After the first scan, the polymer rush is quenched, instantly followed by a second scan. This helps in evaluating the thermal properties of polymers.

- ^{1}H NMR (proton nuclear magnetic resonance):

  This method is used to the changes in the chemical composition of a polymer during degradation.
- ESI—MS (electron spray injection mass spectroscopy):

  This method is used to evaluate the molecular weight of polymers. It follows the appearance of a low-molecular-weight polymer during degradation.
- Weight loss:

  Weight loss exhibits the oligomer release from the bulk polymer during the degradation process.

1.4.1.2 Biological methods

The biological resorbability of polymers is determined by using cell culture techniques. Generally, this depends on the cell culture at the material surface and the types of cells used. The selection of a specific cell type is required, which comes in contact with the biomaterial after the implantation process. The appropriate shape and size of the material is the next step after cell selection. The material selection is a significant step as it determines the adhesion and nonadhesion ability of the cells. After implantation, biological fluids consisting of proteins are adsorbed on the material surface.

The adsorption of proteins depends on the material properties, such as the thickness and quantity of the protein layer. Material roughness also plays a major role. The greater the roughness, the higher the concentration of protein deposited on the surface. The adhesion ability also depends on the material's positively and negatively charged surfaces. A positively charged surface induces cell adhesion and proliferation; however, a negatively charged surface shows a very low amount of cell adhesion. The pH of the cell culture medium can modify the surface charge.

Scanning electron microscopy (SEM), transmission electron microscopy (TEM), contact microscopy such as profilometry, and scanning probe microscopy (AFM) can be used to evaluate the bioresorbability of polymers.

1.5 Bioresorbable polymers and their biomedical applications

There are numerous applications of bioresorbable polymers and their composites. Generally, bioresorbable polymers find their applications in the biomedical sectors. Drug delivery, tissue scaffolds, tissue repair/regeneration, implants, etc., are some examples of bioresorbable composite applications. The following section discusses the research and applications based on bioresorbable polymers and their composites.

Hao Yang Zhang and co-workers (Zhang et al., 2020) developed magnesium-based PLA bioresorbable membranes for guided bone/tissue regeneration. The hot pressing method was used for developing the membrane. Two PLA membrane with AZ91 was hot pressed to make a PLA-fluoride AZ91 bioresorbable membrane. The developed membrane exhibits a higher maximum load and stiffness than the PLA-only membrane. FAZ91 exhibits a major degradation, so PLA-FAZ91 is completely degraded within 16−20 weeks. Based on this, the developed membrane is a better option than the PLA membrane for guided bone/regeneration applications.

Anjumol Joy and co-workers (Joy et al., 2023) have developed graphene-based gold nanostructures with polycaprolactone nanocomposites exhibiting potential biological and physicochemical properties. Different characterization techniques (SEM, TEM, XRD, XPS) confirmed the adhesion of gold nanoparticles over the graphene sheets. The biocompatibility of the developed nanocomposite was confirmed using hemolysis tests. Also, the developed nanocomposite exhibited biodegradability, biomineralization, and cell viability for bone tissue engineering.

Bioresorbable polymers exhibit magnificent applications in biomedical fields. Neural tissue engineering is another significant field in which biopolymers are frequently utilized. Yurena Polo and co-workers (Polo et al., 2021) fabricated bioresorbable polymer PLCL with graphene oxide using compression molding. Murine neural stem cells are attached to the surface of the scaffolds without any extracellular matrix coating. The neural stem cells bring immature neurons and glial cells over the scaffolds, advancing their migration into cell groups. The developed scaffold exhibits potential in cellular therapy and nerve tissue regeneration.

Bioresorbable-based polymer composites have been found to be one of the most promising replacements for metal-based implants. An in situ polymerization and laminate stacking process followed by compression

molding process are used to develop phosphate-based glass fiber-based polycaprolactone composites (Chen et al., 2016). Different phosphate fiber volume fractions were used for developing the bioresorbable composites. Figs. 1.4a and b exhibit the pH variation (PBS solution) for PCL and PCL-PGF composites developed by using laminate stacking and in situ polymerization. pH neutrality for both PCL composites (laminate stacking and in situ polymerization) was observed at 7.4 ± 0.2 until degradation. This pH neutral value is observed until the 11th day, followed by a gradual decrease until 28 days (Fig. 1.4).

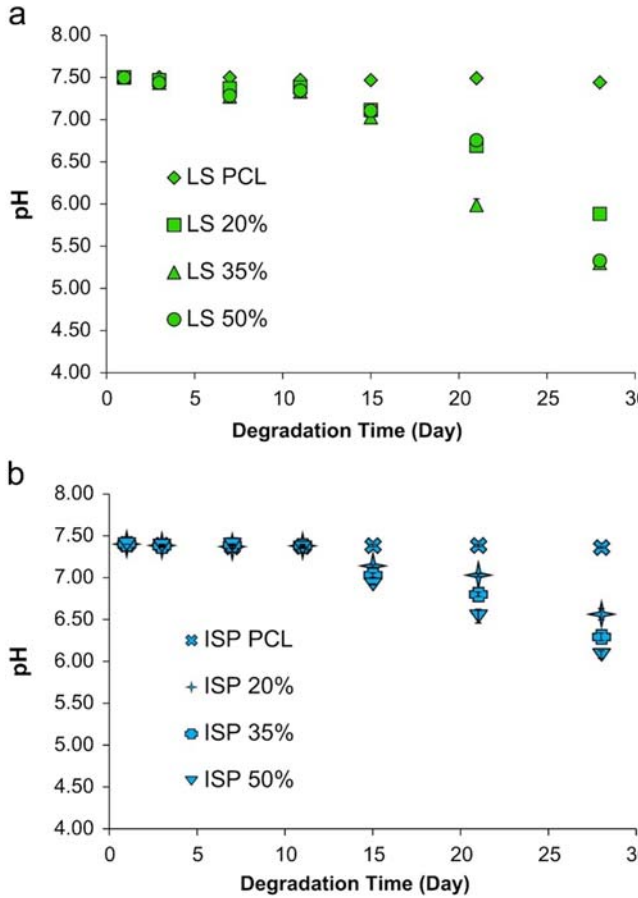

Figure 1.4 pH-based degradation of composites (PBS media): (a) Laminate stacked PCL and PCL-PGF composite; (b) in situ polymerized PCL and PCL-PGF composites. *(Reproduced with permission from Chen et al. (2016).)*

Katarzyna and co-workers (Polak-Kraśna et al., 2021) analyzed bioresorbable semicrystalline PLLA for stent application. Mass reduction, molecular weight, thermal properties, crystallinity, and tensile properties were evaluated by immersing in PBS at 50°C for 112 days. It has been observed that the tensile strain decreases rapidly at day 49; however, other tensile properties remain constant. This polymer has been observed to be one of the optimum options for vascular stent applications.

Constantino Fiuza and co-workers (Fiuza et al., 2022) evaluated the mechanical, micromechanical, and physical properties of Reva Fantom Encore bioresorbable scaffolds. These bioresorbable scaffolds were immersed in a PBS solution at 50°C for around 112 days. Radial compression testing, nanoindentation, DSC, and mass loss were evaluated at different intervals. Three phases of degradation are observed. One phase was observed from 0 to 21 days, the second phase was observed from 35 to 54 days, and the third phase was observed between 63 and 112 days. During the first phase, bioresorbable scaffolds' radial strength, stiffness, and melt temperature increase, and the molecular weight decreases. However, during the second phase, the radial strength becomes constant as in the first phase, but molecular weight again decreases. During the third or final phase, continuous reductions in radial strength, stiffness, and load-bearing capacity were observed.

Oosterbeek and co-workers (Oosterbeek et al., 2022) studied the mechanical properties of bioresorbable polymer–glass composites at degradation. Polylactide polymer is reinforced with 15–30 wt.% of the phosphate glass fiber, which results in an 80% increase in modulus. However, 15 wt.% glass incorporation holds comparable ductility to pure polymer. Ductility and stiffness are the two most significant properties required for stent applications. Including glass fiber suppresses polymer embrittlement, resulting in a controlled reduction in mechanical properties that gradually permits the load transfer to the healed tissue.

Chaigneau and co-workers (Chaigneau et al., 2023) developed PLA-bioactive glass-based composite scaffolds using fused filament. Because of the deficient mechanical properties of the bioactive glass–PLA composites, the bioactive glass is coated with a thin layer of gold which not only improves the mechanical properties of the PLA–BG composite but also shows good cytotoxicity.

Boccaccini and Maquet (Boccaccini and Maquet, 2003) developed a bioresorbable polymer–bioglass-based composite for tissue engineering applications. A bioactive glass particle-incorporated PLGA-based foam

composite was developed by using a thermally induced phase separation technique. The developed foam composite exhibits interconnected, well-defined porosity. Phosphate buffer solution (PBS) was used to check the degradation rate of the developed foam structure after a maturation period of 7 weeks. It has been observed that bioactive glass slows down the degradation rate of the foam structure for the suggested time period of investigation. Hence, the incorporation of bioactive glass could be the controlling factor for the evaluation of the degradation rate of a polymer.

1.6 Conclusion

The role of bioresorbable polymers in biomedical uses has become noteworthy due to their application in areas such as tissue healing, cardiovascular stents, neural stem cells, tissue scaffolding, drug release, dental work, and surgical implants. The major advantage of bioresorbable or degradable implants is that a second surgery is not required for their removal. Bioresorbable polymers find numerous applications in organ transplant, tissue engineering, orthopedic autografts, alternate tissue, and cell grafts/constructs. Numerous cases of organ transplants are observed each year. Bioresorbable polymer-based implants could be a boon for those waiting for organ transplants, including in emergency situations.

The technology is still developing in neural tissue engineering/regeneration. Bioresorbable-based drug-eluting stents are showing magnificent advantages/benefits for those who suffering from cardiovascular blockages, as they provide easy flow through the blood arteries to the heart. Apart from these, there remain some challenges into which numerous researches are ongoing. These challenges are related to the properties of the bioresorbable polymers/materials used for implant applications.

Detailed knowledge of material characteristics related to material degradation is required for tissue regeneration applications. Various factors influence the properties of bioresorbable polymers, such as drug incorporation, growth factors, enzymes, and proteins. Based on such factors, the application of the bioresorbable polymer-based implant for specific organ replacement is decided. Implant degradation and tissue regeneration are the primary objectives of a bioresorbable implant. However, one should still have proper knowledge of the degradable polymers and their characteristics for designing tissue engineering for future physiological functions.

CHAPTER 2

Bioresorbable polymers and their composites for biomedical applications

Oludaisi Adekomaya and Thokozani Majozi
Sustainable Process Engineering, School of Chemical and Metallurgical Engineering, Faculty of Engineering and Built Environment, University of the Witwatersrand, Johannesburg, South Africa

2.1 Introduction

Adaptation and full integration of bioresorbable materials in medical applications has been described in a number of published works (Adekomaya et al., 2017b; Lambert and Wagner, 2017). This is against the backdrop of their applications in many energy-saving devices, most importantly, their vast use in building and vehicle component parts. The use of bioresorbable materials has been widely promoted basically for their lightness and fast degradation properties (Sun et al., 2016). These materials serve largely to protect the environment amid global climate change and the attendant repercussions. This has also resulted in several measures being evolved in which bioenergy and biobased materials were promoted as part of stopgap measures, thereby creating the opportunity to explore key qualities ascribed to their renewable properties and sustainable characteristics (Szendiuch, 2011). The biobased industries have explored the intrinsic biocompatibility and biodegradability of bioresorbable materials to alleviate human problems in a number of areas, where efforts have been made to use some of their salient properties to combat climate threats, thereby leading to a reduction in greenhouse gases emissions (Cheung et al., 2009). The use of synthetic fibers as a complementary materials in the medical field has been a subject of debate in the literature (Adekomaya et al., 2017a) in which their key advantages of low cost and high strength have been criticized on the basis of prevailing recycling and reuse complexities when trialing their use over many years. Part of the issue raised involves the structural problems associated with the use of these materials, culminating in a serious environmental problem as has been reported in several developing and emerging countries (McCullen et al., 2010). The awareness of climate change is reverberating throughout the planet, necessitating a new modern method

Bioresorbable Polymers and their Composites

of recycling and reclamation of composite materials (Lau et al., 2010). Environmental legislation is now part of the fulcrum on which sustainable development has been built, thereby creating a discourse around materials with less risk to the environment. The human impact on the environment is huge and unprecedented, as the world struggles to cope with the increasing global population (Adekomaya and Majozi, 2020). This had led to competition among species, in which human activities take a large toll on the environment. There has also been a paradigm shift and material diversification in the production and manufacturing industries. This has been fully implemented in many developing countries around the world in which companies and production factories take ownership of the environmental impacts of their products. The law also mandates each company to file returns for every action taken to mitigate the environmental crisis arising from their operation. The policy is in line with a sustainable approach to material evolution and to protect the environment from unnecessary attack and degradation. Some of these policy actions were created in the United States where manufacturers are mandated to evolve best practices in terms of materials and products by adopting the 4Rs, in line with internal best practices: (1) reduce the quantity and proportion of toxic wastes to be disposed of (sourced reduction); (2) reclamation approach in which materials and used products are reused in an environmentally friendly manner; (3) repairing the environment in a sustainable manner; and (4) recycling approach in which measures are put in place to buy products made from recycled materials (RameshKumar et al., 2020; Adekomaya and Majozi, 2019). It is also important to continuously use all these aforementioned methods before waste materials are sent for open disposal or landfilling.

Natural fibers and bioresorbable composites continue to enjoy patronage in regenerative medicine and other related applications, in view of their biocompatibility, biodegradation rate, and ability to degrade into nontoxic components, which are often traceable to natural polymers, such as polysaccharides and synthetic reinforced polymers. Considering the safety of materials and the efficacy of the results desired for the application of bioresorbable materials, it is necessary to study the inherent properties of these materials before application. This must be considered in the deployment of biomedical applications in view of their direct contact with the human body. There are also clear-cut specifications which must be adhered to before they can be used. The use of polymers and natural fiber reinforced composites has given considerable leverage to their biomedical

application as they are flexible in terms of materials sourcing and life cycle assessment. In several papers published on this subject, the findings have shown that natural materials have been identified as among the most attractive options, which may be connected with their extracellular matrix and compatible characteristics with the human body. These materials are chemically stable in nature, are modifiable where necessary using chemical methods, and are capable of showing result-oriented biological performance. Generally, bioresorbable materials occur in nature and are mostly processed from plants, animals (invertebrates and vertebrates), or microorganisms. In other papers (Adekomaya, 2020), they are often referred to as polysaccharides, proteins, or glycosaminoglycans (GAGs). Natural polymers in other areas are modified structurally and can also be extracted from synthetic materials and used for medical aids, with ingredients embedded in them to complement medical and industrial uses. Findings have shown that most bioresorbable materials have been accepted for biomedical research as studies show their effectiveness and non-immunogenic properties when subjected to several tests. In other works, they are also noted for their preference over synthetic polymers, where the latter often pose an environmental challenge (Adekomaya et al., 2020). Going by the characteristic tendencies of synthetic biodegradable materials, one may be tempted to believe that these are commercially competitive polymers with similar emerging results, as they are often produced in a cost-effective manner. It can also be seen that, in commercial products, one of the most notable materials is polyesters, which acts as a biologically inert material in the sense that it reinforces materials or it can be modified to support other contending issues such as low cell compatibility, hydrophobicity, and inflammatory impacts. In many other papers (Upgupta et al., 2015), it has been reported that the preferred materials being used for biomedical applications are largely obtained from biodegradable sources due to their effectiveness in the healing process. These materials have been used as a stopgap measure, considering the reclamation and environmental disruption associated with natural resources. The world is faced with an existential threat and the indiscriminate use of natural resources could complicate the already dire situation that we face currently (Yang et al., 2015). Biodiversity losses are of great concern across the globe and these follow disruption in climatic weather conditions occasioned by the loss of fauna and flora (van Gameren and Zaccai, 2015). In order to explore natural polymers for the purpose of biomedical applications, it may be necessary to dissect some of the available materials being used and discuss how best to improve their functionalities.

In some cases, materials like polysaccharides exhibit products in the form of cellulose and starch, whereas, in other cases, these polymers are regenerated by fungi and nature. However, findings have shown that other natural polymers, such as proteins, could be deployed to produce natural fiber materials which would be suitable for biomedical applications. In this chapter, a detailed review of the bioresorbable biopolymers and their contributing impact in the biomedical field is discussed in this section detailing the properties of the materials in tackling human deficiencies as reported in many earlier works (Lau et al., 2018). It is also very important to discuss the contributing impact of the adjoining matrices in the entire value chain, so that if the reinforced natural fiber is to used, one is able to know whether the supporting materials could pose a danger to the application in which they are meant to be used. This has been the major concern in much of the literature, because materials production has been complicated by the evolution of composite materials containing various amounts of similar and different elements as constituent materials (Ayrilmis et al., 2011). The involvement of bioresorbable materials in biomedical applications has many advantages. The bioresorbable materials are also not reputed to posses serious threat to the environment since its component parts naturally decomposes with no side-effects to the nature. Bioengineering, as conceptualized in many biomedical applications, refers to any concepts and methods in which science and mathematics play a critical role in solving problems related to the repair and reconstruction of parts of the human body which may have been either lost, damaged, or contain dead tissue. The process of applying materials suitable for addressing these gaps can be regarded as biomaterials. As discussed in several published works, a biomaterial is a material deployed for medical devices, that aims at addressing the shortcomings occasioned by inadequacies in human parts, and is directed to interact with biological human systems. Several of the medical devices available for these applications are seeing breakthroughs in the evolution of artificial hearts and hips, in which these products are bioresorbable. A substantial part of the advantages of biomaterials is that they can be tailored based on the existing complications prevailing in the human system with the aim of meeting the deficiencies as reported (Xie et al., 2010). In the past, the most common conventional materials used were produced from synthetic compounds ranging from phenolic reinforced compounds to those reinforced with natural fibers (Faruk et al., 2012). These have led to several complications in regenerative medicine where the composite structures of these materials do not serve their

intended functionalities after their shelf-life, as the components are closely interconnected, and are thereby difficult to reuse after operational use. In the bone reconstruction method, several papers have recommended stainless steel and titanium as a sustainable bone plate materials due to their quick recovery tendency. However, there have been concerns about the side effects of these materials for bone replacement as unconfirmed reports have claimed that many surgical operations aimed at removing the bone and replacing it with commensurate biomaterial fasteners have resulted in delayed recovery and healing. This had reportedly caused uneven growth of bone cells underneath and round the bone plates, causing porosis. Refracture of bones around the insert may also occur after plate removal occasioned by differential stiffness between the bone and the plates. As shown in Table 2.1, the mechanical properties of some of these materials have been analyzed based on their implant application. This analysis also shows the detailed analysis of bone structure and properties, with detailed prediction of other materials for the same use. As shown in this table, it can be seen that less stiff materials should be deployed for bone fixation. Another material of high interest is poly(lactic acid) (PLA), which has considerable properties similar to biodegradable and bioresorbable materials (Amulya et al., 2021). Their strong advantages over other materials include that they can serve as a dual purpose without inflicting pain on the human body. However, studies have shown that a degradable implant may be removed naturally after the operation is completed, thereby making

Table 2.1 Mechanical tendencies of implant materials for regenerative medicine.

	Elastic modulus (GPa)	**Yield strength (MPa)**	**Tensile strength (MPa)**	**Elongation to failure (%)**

bioresorbable polymers the most sought-after materials for biomedical applications (Suddell, 2008). The only concern about bioresorbable materials is the possibility of them becoming susceptible to external and internal moisture if chemical treatment fails. There have been several rebuttals in the literature in which this shortcoming has been shown to be minimal and to not occur in the operation theater. Another concern is the poor strength of the bioresorbable polymers which could inhibit their wider application.

2.2 Salient properties of bioresorbable materials for biomedical application

Over the last few decades, the use of bioresorbable materials has experienced wide patronage in all areas of human endeavor (Abiola et al., 2014). This has taken a toll on the use of natural fibers, with these becoming the immediate casualties among the types of materials used for biomedical applications. The key part of this work is to preserve natural resourses from severe threat and other anthropogenic activities. Findings have also shown that they are environmentally friendly composites in which the waste products constitute a lower or negligible effect on the environment (Jayaramudu et al., 2011). Further advances in natural fiber development have been reported in the literature, most importantly, in the areas of genetic engineering and composites science. Some of these approaches have created significant opportunities in the medical field, in which plant materials are interchangeably used to ensure environmental conservation. It is important to take cognizance of their nature, so as to mitigate biodiversity loss as we explore natural resources for medical improvements. In order to achieve precision in some of these giant strides, it is imperative to study the properties of bioresorbable fibers to know precisely some of the salient properties that can be explored for medical use (Liu et al., 2013).

Table 2.2 illustrates the physical properties of some of the bioresorbable fibers used in medical applications. These features also make their application attractive in other areas of human endeavors. A material of biomedical engineering must possess many specific characteristics, which are different in terms of what was originally designed. In the case of domestic-used plastic products, a lot of work needs to have been done to ascertain the chemical properties of the materials prior to their being adapted for any other purpose, most importantly medical needs. One of the most fundamental requirements revolves round biocompatibility, taking into consideration its adverse effects on host tissues (Asokan et al., 2009).

Table 2.2 Properties of bioresorbable materials for medical applications.

	Tensile strength (MPa)	Elongation at break (%)	Young's modulus (GPa)
Natural fibers			
Flax	300–1500	1.3–10	24–80

Cotton	264–800	3–8	
Skin	7.6	77–81	

Hence, the properties of the parent materials provide a detailed and overview analysis of their component elements before they can be subjected to further analysis or use. In the case that there are variations in the composite materials with poor reinforcement, they could be replaced with bio-engineered composites. In another analysis, as presented in Tables 2.3 and 2.4, the properties of polymers, and bioresorbable and biocompatible materials with their illustrative applications are presented. This could provide the basis for the in-depth analysis of bioresorbable materials in their quest to solve a growing gap in the deployment of these materials for other needs (Leal-Egaña and Scheibel, 2010). The properties of materials provide a clear understanding of the nature, origin, and behavior of materials after years of applications. Fig. 2.1 is a typical illustration of the chemical properties of some bioresorbable polymers. Polyethylene (PE) in high-density (HDPE) form, as it appears in some of the most common applications, is a lightweight material that may not cope with the sterilization temperature range. Polypropylene (PP) is one of the isotactic crystalline polymer materials with a high possibility of being rigid, with moderate chemical resistance and considerable strength, and the possibility of

Table 2.3 Properties of polymers.

Type	Thermal properties	Construction/useful form
Synthetic polymers		
Polyethylene (PE)	$T_m = 203-208°C$	Heath care products, lightweight
Polypropylene (PP)	$T_m = 223-233°C$	orthopedic casts, ligament prostheses
Poly(tetrafluoro-ethylene) (PTFE)	$T_m = 313-315°C$	Surgical drapes, and gowns
Nylon 6	$T_g = 45°C$, $T_m = 220°C$	Vascular fabrics, heart valve sewing

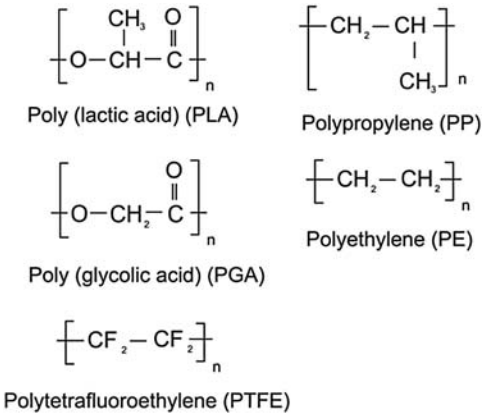

Figure 2.1 Chemical structures and behavioral properties of some bioresorbable and bio-degradable polymers.

possessing a higher fracture toughness as compared with HDPE. Polytetrafluoroethylene (PTFE) is also reputed to have a high melting point ($T_m = 312°C$) and moderate crystallinity as its features. PLA and PGA are often used in resorbable surgical sutures together with their copolymers. In many earlier works, the findings have shown that the degradation process and the emerging products are endogenous compounds and may not be toxic. As shown in these tables, it is noted that those synthetic materials being used in biomedical applications possess good thermal properties as compared with bioresorbable polymers. However, other findings and analyses indicate that the mechanical properties of some polymers are comparatively high when compared with existing materials for use in regenerative medicine (Sanjayan et al., 2015). However, a great deal of improvement has been reported in the enhancement of the physical properties of polymer materials but some lapses and drawbacks remain largely unaddressed. Generally, biocomposites are made up of synthetic polymer as matrix and natural fibers to support the fibers' moderate toughness, good specific strength, high thermal properties, separation flexibility, and biodegradable tendency. Bio-fibers, if they possess the highlighted properties, are often chosen as reinforcements since these features enable them to improve the tool wear properties when used for respiratory interventions. In another report (ul Haq et al., 2014), these fibers were constrained as a result of their small cross-sectional dimensions and they were unable to perform optimally in engineering applications which made them become embedded in matrix layers to form biocomposites. The

matrix may be used as a binder to bind the fibers intact and convey the loads to the fibers. An understanding of the chemistry of natural and synthetic materials is necessary to fully understand how their physicomechanical properties behave in biomedical applications (Li et al., 2007).

2.3 Performance of bioresorbable materials in medical interventions

The human body system is comprised of several tissue structures which may be classified according to the musculoskeletal system involving the integration of other human structural members ranging from skin, ligaments, nerves, and muscles, etc. In order for adjoining bones to co-exist in the human system, including fibrous and adjoining layers, this involves the integration of synovial and diarthrodial joints in which some degree of kinetic activity is activated (Davis and Song, 2006). The plan to use bioresorbable materials as a leverage for diarthrodial joints is an intervention approach for the protection of articular cartilage, which presents itself in translucent tissue parts, with the possibility of forming articulating surfaces in the diarthrodial joints (Amulya et al., 2021). The articular cartilage is composed of a tissue-related cellular matrix comprising of a sparse composition of embedded chondrocytes. The extracellular matrix (ECM) is naturally designed in such a manner that it forms insoluble tightly woven fibers, in the form of water and proteoglycan distributed to create the shape of a biphasic matrix. The involvement of fibrils is partly because of their ability to withstand tension but they can be susceptible to compression in application, and it is advisable that the matrix possesses high tensile strength, and in the case of proteoglycan macromolecules, they are reinforced with articular cartilage, making them able to withstand compression in the event of moisture interaction. The reinforcement of the cartilage structure, being a support system, is meant to support the joints' interactions with other organs, thereby reducing their wear resistance. This makes articular cartilage involved in steady compression which is often viscoelastic at every relaxation. Reports claim that its disadvantages are characterized by chronic diseases, child growth retardation, complicated trauma disorder, and other complications. These deficiencies could bring about the distortion of tissue to conform with the self-recovery effort, resulting in a full-thickness disorder. It is also important to examine the nature of some of these tissues in most regenerative procedures (Mayer et al., 2019). This also makes it difficult for them to have contact with blood, making them display a low

cell-to-matrix ratio. The findings have shown that more than 900,000 Americans display some form of articular cartilage injuries every year that require several transplants. This makes the situation worse in organs transplanted from similar donors due to the shortage of compatible donors. Given the circumstances arising from organ transplants, tissue regeneration through biomaterials offers a sustainable method for bridging the gap with the prospect for exploring more viable alternatives in biomedical materials as against surgical procedures (La Mantia and Morreale, 2011). Several years ago, a number of surgical operations were deployed to improve fractured cartilage which are now aimed at the treatment of injuries arising from tissue relief and dysfunctional cell structures. As it stands, three approaches are currently being activated in regenerative engineering: (1) the application of cell parts to serve as a replacement for damaged cells; (2) the application of cell materials in a specific location with a clear focus on modifying diverse factors; and (3) cultivating new cells in three diverse scaffolds. In a related development, three general principles are generally adopted for joint repair, these include: (1) reinforcement of different healing potentials of cartilage, (2) development of new cartilage with objective transplants, and (3) restoration of the cartilage interface with the adjoining cartilage. However, the findings have shown that the use of suspended cells for interfacing with chondrocytes in some transplants has certain limitations in theory and laboratory simulations. In addition, in vivo cells may display three-dimensional layers, in the form of cells in three-dimensional substrates that showcase scenarios that may reflect the results. To reduce these challenges, three-dimensional structural cells with matrices could be investigated for tissue engineering to study their features depending in vivo implantation or to promote cell repair.

The application of regenerative medicine has been shown to be effective in therapeutic control for the thorough replacement of damaged tissues and organs. Part of this method involves the production and replacement of scaffold materials in the place of a surrogate framework which aids tissue populations in order to translate them into equivalent and complementary cell parts. The adaptation of scaffold-based strategies in regenerative medicine has been shown to be most useful in three-dimensional platforms incorporating some of the features such as biocompatibility and biodegradability in some of the operational structures in order to provide an effective in vivo cell expansion for maturation. This may also aid in natural tissue development and the healing of many tissues in relation to their biochemical composition, morphological adaptation, and physiologic

function. The involvement of biomaterials in medicine has incorporated several methods, including naturally induced, synthetic, and hybrid bioresorbable materials to promote regenerative and safe healing (Adekomaya et al., 2017a). For these materials to be fully adapted into scaffolding, taking into consideration the process of tissue replacement, some techniques have been explored in the literature to develop materials with three-dimensional structures for cell growth, which provides an underlying tissue property with mechanical stability of the cell. The structural and background discourses for tissue replacement have been directed at damaged cells, with the aim of using scaffold biomaterials that are similar in chemical and physical composition to the isotropic nature of the materials including their considerable mechanical properties. It is important to adopt sustainable approaches and methods to develop scaffolds that have similar properties to the original tissue with some features such as nanoscale representation and biocompatibility, that continue to generate reactions and new methodologies for material fabrication. Scaffolding in cell repairs has focused on different approaches while accommodating bulk hydrogel materials or plant materials. Bulk hydrogels have been developed to provide a three-dimensional homogeneous platform that is suitable to bridge a fracture in the tissue adjacent to in vivo growth (Cheung et al., 2009). Hydrogel materials have been tailored through their chemical composition in such a manner that the pore size and mechanics of their structures are properly aligned. Some of these materials can be processed in microenvironmental structures depending on their properties and physical composition which may capture natural and synthetic components of the materials. In the case of synthetic hydrogels, these were fabricated from poly(ethylene glycol) and have been reported in a number of works depending on their decomposition mechanism and bioactive properties. Several of these processes have been undertaken in such a way that the growth factors or biomolecules are based on their interaction between the density and chemical composition of individual materials (McCullen et al., 2010). Some of the hydrogel materials which are often naturally occurring may be examined to provide sources such as hyaluronic acid-modified hydrogels and agarose. Part of the advantage of these materials is that they have been tested in practice to sustain equal cell conformity and a high tissue viability in cell repair. Also, there have been restrictions in the efficacies of these materials due to their heterogenic nature as indicated in batch-to-batch processing of some of their products. Substantial shrinkage has also been reported in some of these adaptive materials due to compatibility errors and poor mechanical

properties. There are several other ways in which these biomaterial properties can be structured by cross-linking, resulting in gel networks characterized by weak properties with moderate moduli depending on the transition from Pa to kPa. Moreover, in an attempt to increase the aggregate modulus, findings have shown that some of the resulting products could be limited in terms of permeability, diffusion, and the inability of repaired tissues to absorb nutrients and discharge unwanted products. There are also reported cases of structural heterogeneity in some of these products, making it a major disadvantage in the usage of hydrogel systems. Several other new approaches have been advanced to produce tissue materials with different geometries, including mechanical properties and uniformity in porosity, and anisotropy. The relationship of cells among other extracellular matrices is part of the effect in multi-cell matrix deposition, along with other resultant properties of the cellular materials. Several techniques have been recommended for the progression of scaffold fabrication in tissue-related medicine. Fiber-reinforced materials have long been used as replacement options in tissue repairs with complicated applications ranging from vascular grafts, hernia replacement tissue, etc. Fiber reinforcement could be adapted to suit particular operations depending on the properties of biomaterials needed to complement tissue repair applications. Findings have also shown that fiber reinforcement can be tailored to a variety of configurations in order to enhance the physical structure and mechanical properties of biomaterials based on the specific application and interest. In other areas, fibers are often arranged from monofilament yarns and could also be substituted to fit many substrates that can accommodate woven, knitted, braided, and randomly aligned materials. In the case of aligned fibers, the method could also be used in a spatial oriented arrangement that can be structured into any patterns ranging from angle-ply and cross-ply arrangements. The use of fibers as component parts of biomaterials depends largely on the orientation of the fibers, fiber volume fraction, physical attributes of the matrix, fiber—fiber contacts, and fiber—matrix ratio (Lau et al., 2018). The importance of using fibrous or natural materials including fiber and silk materials is that they can be tailored depending on the specific area of application in which the properties, such as extremely high porosity and good mechanical properties, are desired.

Several advances have been made to improve the fabrication techniques of biomaterials leading to diverse new ideas for both emerging products and therapies as they are used in the biomedical field. This has led to the development of many biomedical materials that have been deployed in

medical trials. Many studies were carried out a number of years ago to explore the possibilities of using natural materials, together with different types of fiber materials, to evolve a new class of biocomposite. This was done to create a clear departure from synthetic fibers that have been adapted for medical use (Rana and Jayachandran, 2000). The use of natural fibers has created a new area of knowledge in which several discoveries have been made on the use of bioresorbable materials and the progress needed for these to be advanced in the foreseeable future. Reports have also shown that some biological requirements may enhance the growth of cells and the porosity of the natural materials to fast-track cell growth and healing, nontoxicity of fibers, and fabrication techniques. Cellulose, which is one of the most highly sourced materials from processed cotton, is the most common fiber-forming biopolymer. Considering its absorbent nature, it is used in the production of hygiene products, diapers, and other absorbable applications. Some reports have also noted that they could not be used in vivo because of the highly inflammatory reactions associated with these materials. Findings have also created a growing interest in some of the natural fibers sourced from polysaccharide compounds comprising alginates, chitosan, dextran, and cellulose. Apart from cellulose, it is also important to source complementary resources which are dependent on natural fibers and more abundant, in the form of animal filaments. Their properties are of considerable interest to material engineers due to their rare structural properties, and by extension as reinforcement materials (Zaman et al., 2012).

2.4 Conclusion

This chapter has discussed the potential properties of biodegradable materials in regenerative and biomedical applications. Bioresorbable materials are derivable from natural fibers and are a suitable medium for several human needs. Natural fibers being biodegradable materials are faced with reclamation and replenishment challenges, including environmental vulnerability and biodiversity loss. Bioresorbable materials have been extensively used in the automotive industry in view of their lightness and payload reduction. This role has made natural fibers of high demand in several areas of human activities. Several features of biodegradable materials have made them complementary to regenerative medicine but there is always a shortfall in the procurement of these materials for further medical uses. this review chapter has also illuminated how important polysaccharides

and protein-based materials could be in the medical field and also to examine the potential of nanocellulose-based materials for biomedical applications. In the future, the demand for natural polymers in regenerative medicine will surpass the current demand thereby making natural material susceptable to environmental degradation and natural disasters. While natural fibers continue to find a market in biomedical applications, including wound dressings, tissue engineering, and scaffolds remolding, this may not be applicable to synthetic materials. There are also conflicting findings on their in vivo use as a complimentary support for biomaterials, where reports from the field run contrary to this claim. Bioresorbable materials, as reported in this chapter, provide a source for alternative materials for biomedical engineering in which alternative materials can easily be deployed where necessary. In consideration of bioresorbable materials for medical interventions, there is always concern about the characterization of materials to meet the required objectives. Natural materials are biodegradable in nature and as a results they tend to support the healing process better than other materials. Part of the shortcoming of natural fiber-reinforced composites is their water absorption tendency, which can result in poor compatibility. This effect may inhibit their performance in the medical field as pointed out in much of the literature. However, chemical treatments of these materials have shown good modification and better results in many cases. In order to enhance the properties of bioresorbable materials for the medical field, one may have to devise techniques to produce high-strength and improved inherent properties of these materials to conform with some of the regenerative drugs and other therapies required for the entire ecosystem. It is also important to consider other properties of natural fibers, such as pore size, degradation rate, and surface morphology, in order to ascertain the direction of application and sustainability of these materials in term of their high strength and compatibility to support healing and regenerative medicine. This may support the replacement of synthetic polymer and metallic-based materials in the medical field. The use of bioresorbable materials as a reinforcement to produce basic natural materials as well as control their biodegradability/bioresorbability is one of the most promising ongoing research areas. This research is multi-faceted, comprising diverse backgrounds to resolve how best to produce materials that can meet multiple requirements in all applications.

Acknowledgments

The lead author acknowledges the financial and institutional support provided by University of the Witwatersrand, South Africa, through the Research Office and the University Research Committee, upon which the postdoctoral fellowship was funded. The authors also appreciate the anonymous reviewers whose comments contributed positively to the final manuscript.

CHAPTER 3

Processing techniques for bioresorbable-based composites for medical device applications

Nadda Chiaoprakobkij[1] **and Manunya Okhawilai**[1,2]

3.1 2D structure

Thin film is one of the most common 2D structures. The materials are dissolved in solvents and cast in a flat template. The solvent is removed from the film's structure by evaporation. Recently, different types of thin films have become of great demand as they have the potential for low-priced processing with minimal materials usage. Thin films are small in size, and so they can be used to create small and portable medical devices. Thin films can be flexible and lightweight. They are also good candidates where mechanical flexibility and low weight are required. Thin films also allow direct integration of other components on the substrate. Multi-layer systems are possible without the need for bonding.

An implantable and ultra-flexible bone fracture electrostimulation device (FED) from bioresorbable soft and metallic materials has been researched (Yao et al., 2021). The device component was constructed with island-bridge electrodes and pyramid base microstructures. The device was able to adhere to uneven tissue surfaces and generate steady electric pulses reacting to the movements of knee joints. Figs. 3.1 and 3.2 illustrate the design, structural characterization, and fabrication procedure for the FED. The FED consisted of two modules: (1) triboelectric nanogenerator (TENG) and (2) interdigitated dressing electrodes. Both components were set up on the same PLGA substrate. Si wafer mold with inverse square pyramid arrays was produced by lithography technique.

Lithography is the process of transferring a pattern from one object onto another. Electrobeam and optical photolithography are used to transfer a

two-dimensional pattern onto a substrate. Imprint photolithography is used to transfer three-dimensional patterns and structures onto the substrate.

The PLGA polymer solution was spin-coated onto an Si wafer mold and then dried in an oven at 50−100°C overnight to evaporate the solvent. PLGA films were carefully peeled off as P-PLGA layer. Laser cutting technology prepared 2 Mg electrodes with an island-bridge structure.

Cointe and coworkers developed ultrathin and super-stretchable neural probes from the bioresorbable silk layer. A neural probe is one of the key tools in neuroscience for recording electrical brain activity. A flexible probe is in conformity with the surrounding neural tissue. The probes are made of a silk-parylene bilayer. The fabrication procedure and the probe are shown in Fig. 3.3. The fabrication processes consisted of the following three stages: (1) cellulose acetate (CA) is coated with a silk layer, (2) a super-thin parylene-based structure tops the silk layer using the lithography technique, and (3) the whole silk-parylene probe enables microscale shaping by a reaction ion etching (RIE) process.

(h) SEM micrograph of the final bilayered silk-parylene shank, and (i) the magnified SEM micrograph. *(Reproduced from Cointe et al. (2022).)*

RIE, a standard method of dry etching, is used as a micro-structuring process that combines chemical and physical processes. In a sputtering process, ions activate the substrate surface and supply the energy to allow a chemical reaction with the etching gas. The RIE method is attractive due to its well-controlled etching behavior. This etching process provides good control of uniformity, etching profiles, and selectivity. Isotropic (direction independent) and anisotropic directed etching can be achieved.

The bioresorbable magnesium membrane has been fabricated and studied as a barrier membrane for dental surgical guided bone regeneration (GBR) (Rider et al., 2022). The magnesium barrier membrane and its insertion protocol are illustrated in Fig. 3.4.

The barrier membranes were produced from a hot-rolled magnesium sheet. The sheet was trimmed to the desired shapes using a stamping press and die, and each membrane was etched. The membrane was decontaminated by gamma irradiation after etching. The size of each membrane was 30 × 40 mm, with a thickness of 140 μm.

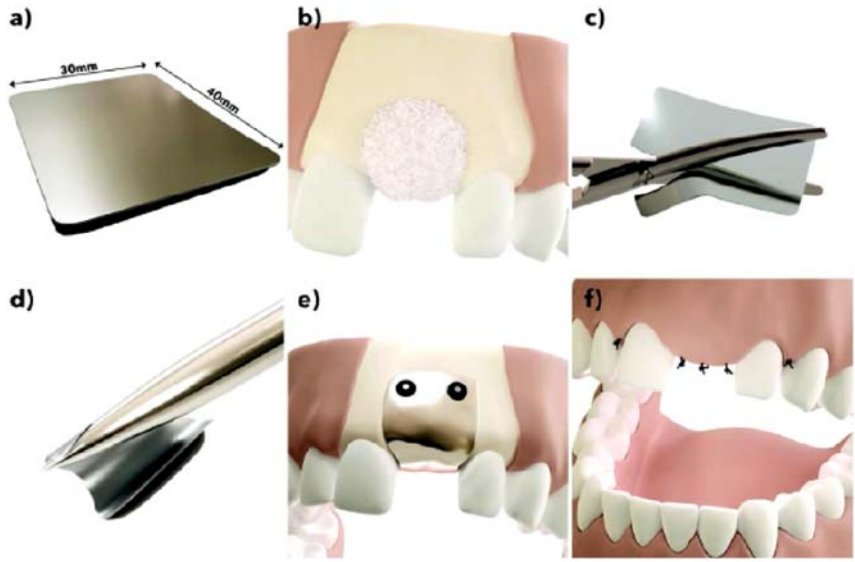

Figure 3.4 The insertion protocol of the Mg barrier membrane (NOVA-Mag membrane, botiss biomaterials GmbH, Germany). (a) The Mg membrane. (b) The defect sites are filled with a bone augmentation material. (c) The Mg membrane is trimmed by a pair of scissors (NOVAMag scissors). (d) The Mg membrane is twisted to fit the defect site contours. (e) The membrane is attached on the buccal and palatial sides. (f) The mucoperiosteal flap is sutured closed over the membrane for closed wound healing. *(Reproduced from Rider et al. (2022).)*

Choi and coworkers developed bioresorbable and stretchable electronic stimulators to promote neuromuscular regeneration. The device is made of bioresorbable polycaprolactone-based polyurethane (b-DCPU) and PLGA. A strip of bioresorbable molybdenum (Mo) in a serpentine geometry with an end opening acts as an electrical extension and connection to convey electrical stimuli from the receiver antenna to nerve tissues. An illustration of a device is depicted in Fig. 3.5. In vivo and in vitro studies revealed that the device could stimulate nerve regeneration.

Lee and coworkers reported a thin, flexible, and bioresorbable nerve simulator for electrical nerve block and pain mitigation (Lee et al., 2022). The developed devices combined bioresorbable metals and polymers. Electrodes and electrical interconnect traces were made of magnesium and molybdenum. A 40 μm-thick layer of PLGA acted as a support for the electrodes. All elements were between a pair of 400 μm-thick polyanhydride (PA). The favorable properties of PA over PLGA mean that it serves as a barrier to prevent the system from interacting with body fluids.

A thin film can also function like a selective nanomembrane. Li and coworker studied a bioresorbable and extremely stretchable electrochemical sensor for nitric oxide monitoring (Li et al., 2020). The device successfully senses the nitric oxide level in living mammals. The sensor consisted of polylactic acid and poly(trimethylene carbonate) (PLLA-PTMC), super-

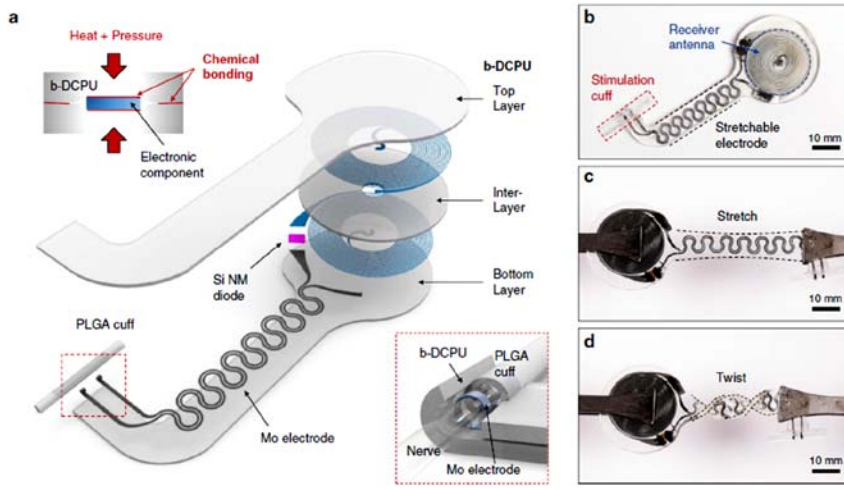

Figure 3.5 (a) The overall design of the device. (b) The photograph of a completed device. (c, d) Photographs of stretched (30%) and twisted (360 degrees) devices. *(Reproduced from Choi et al. (2020).)*

thin gold electrodes, and polyeugenol films. Thin films of PLLA-PTMC were fabricated by being drop-cast on glass substrates followed by gold sputtering.

Another example of integrated biomedical devices using the 2D structure casting method is a strain and pressure sensor. Boutry and coworkers reported the bioresorbable pressure and strain sensor for orthopedic rehabilitation monitoring (Boutry et al., 2018). The thin films of poly glycerol secabate (PGS) were used as a stretchable and nonsticking dielectric for the capacitor. Thin films of poly(octamethylene maleate (anhydride) citrate) (POMac) were employed for strain sensor and packaging. Thin films of PLLA were used as the layer for the magnesium electrodes.

Boutry and coworkers developed a sophisticated bioresorbable and flexible wireless pressure sensor to monitor blood flow (Boutry et al., 2019). The thin film of magnesium interconnected together with the thin film of poly(glycerol scabate) (PGS) for a pressure-sensitive layer. The thin layer of POMac and polyhydroxybutyrate-polyhydroxyvalerate (PHB-PHV) and PLLA were used for the binary coils. The PGS layer enhanced the sensitivity and response time of the sensor. The soft layer of POMac was in contact with the artery. The stiff layer of PHB-PHV was in contact with surrounding muscles. The integrated device was sensitive to artery expansion. The PLLA layer prevented short circuiting between the coil. In vivo studies revealed that the device has minimal hysteresis, fast response time, as well as being wirelessly operated.

A bioresorbable silicon electronic device for the brain has been reported (Kang et al., 2016). A thin membrane of PLGA was adhered onto the thin layer of nanoporous silicon. The silicon nanomembranes were patterned via photolithography and etching. The 100 nm-thick layer of silicon oxide was overcoated by an electron-beam evaporator. In vivo studies in rat showed that the devices could sense pressure, temperature, motion, flow, pH, and thermal properties that were compatible with the body's acute traumatic injuries.

A silicon nanomembrane was also developed into an NO_x sensing system for medical implants (Ko et al., 2020). The devices were equipped with patterned silicon nanomembrane, magnesium contact pad, and polycaprolactone (PCL) substrate. In vitro tests showed that the device was stable in harsh conditions and very hydrated environments for temporary implants.

A bioresorbable spectrometer consisting of a silicon nanomembrane, zinc electrodes, and PLGA optical fibers was studied (Bai et al., 2019).

In vivo studies in mice proved that the device is an intriguing option for measuring the temperature, neural activity, and oxygenation in brain monitoring.

A molybdenum disulfide (MoS_2) bioresorbable sensor was developed by Chen and coworkers (Chen et al., 2018). A monolayer of MoS_2 was patterned by photolithography. The mesh structure was formed by RIE and transferred onto a PLGA thin film. In vivo studies of severe traumatic brain injury in mice confirmed that the developed device was a potential sensor for pressure, temperature, strain, and motion through intracranial monitoring.

Silk fibroin was reported as ultrathin and conformable electrode arrays for neural mapping experiments (Kim et al., 2010). The device was developed and studied in a feline model. The results showed high conformal contact on the brain model with good response to signal amplitude and signal-to-noise ratio.

The bioresorbable composite of PLA-PLGA was integrated with magnesium electrodes as wireless anticancer drug-loaded patches for the treatment of brain tumors (Lee et al., 2019). Tumor volume suppression was observed in canine model studies.

PLGA pads integrated with magnesium electrodes were developed as battery-free implantable cardiac pacemakers (Choi et al., 2021). In vitro studies in rat, rabbit, and canine models showed favorable effective pacing of hearts.

Magnesium-iodine encapsulated with polyanhydride composites were reported as bioresorbable batteries (Huang et al., 2022). The constructed batteries were found to be potential power supplies for cardiac pacemakers.

3.2 3D structure

Solvent casting, in combination with patterning fabrication, works only for thin membranes or 3D samples with a very thin wall. 3D printing is a high-precision technique to produce complex 3D objects that accurately define and control the structure of the manufactured parts. This process is also known as additive manufacturing. It creates three-dimensional solid objects from 3D model files using materials such as powdered metal and polymers, by printing them layer by layer. 3D-printed objects can be printed into any desired shapes and geometric characteristics. The 3D printing technique can be categorized into fused deposition modeling, selective laser sintering, and stereo-lithography, as described below.

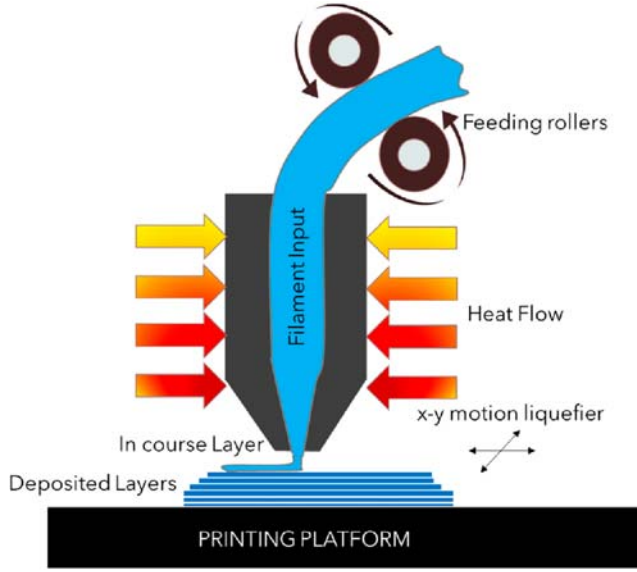

Figure 3.6 Illustration of fused deposition modeling (FDM). *(Reproduced from Ali et al. (2022).)*

3.2.1 Fused deposition modeling (FDM)

Fig. 3.6 shows a schematic diagram of fused deposition modeling.

The filamentous hot-melt material is heated and melted. Then the three-dimensional nozzle can accurately cover the material according to the cross-sectional profile information and set up a layer after a swift cooling procedure. The entire process is under the control of a computer.

3.2.2 Selective laser sintering (SLS)

A schematic diagram of SLS is shown in Fig. 3.7.

The SLS technique uses an infrared laser. This method is carried out by powder spreading. A layer of powder material is spread on the upper surface of the molded part. The temperature required by this technique is just below the sintering point of the material. The temperature of the material increases to the melting point, sintering and bonding with the molded part below after scanning. The control system directs the laser beam according to the cross-sectional profile of the layer.

3.2.3 Stereolithography apparatus (SLA)

The laser used in this method is an ultraviolet laser. A schematic of an SLA is shown in Fig. 3.8.

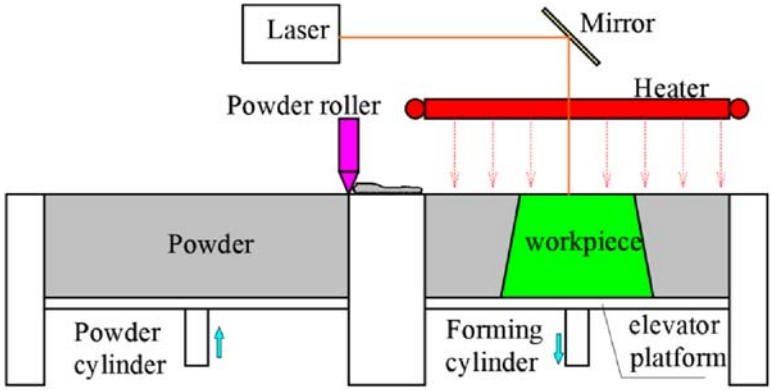

Figure 3.7 Schematic diagram of selective laser sintering (SLS). *(Reproduced from Zheng et al. (2022).)*

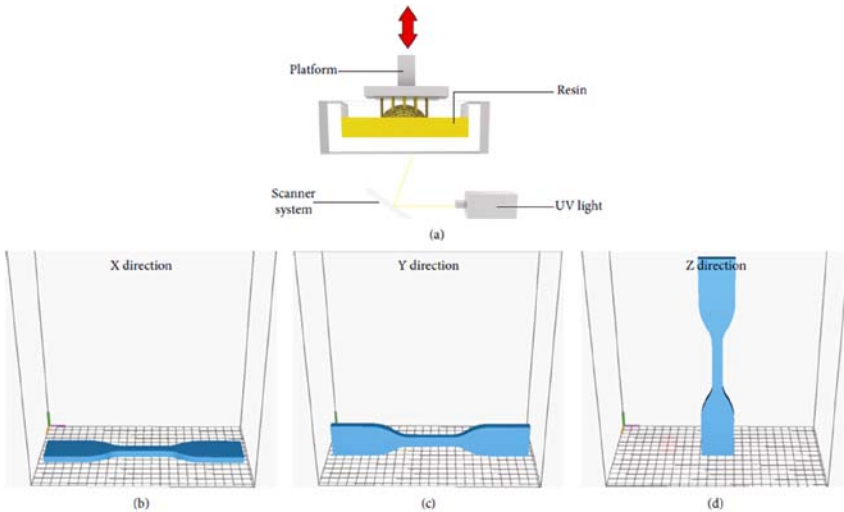

Figure 3.8 (a) Illustration of the SLA process: (b) face up (*X* direction), (c) edge up (*Y* direction), and (d) upright (*Z* direction) of tensile test specimens. *(Reproduced from Feng et al. (2019).)*

The liquid photosensitive resin is stuffed in the tank. It quickly cures under the ultraviolet laser beam. The laser beam scans the cross-sectional profile along the liquid surface. The liquid resin in the scanning is quickly solidified to complete the process of a layer of cross-section and obtains a layer of the sheet. The 3D printing technique is a fast prototyping and customized design with wide material options.

3.2.4 Advantages

3.2.4.1 Flexible design

3D printing can deliver a product with novel designs that can be uniquely shaped and much more intricate than those manufactured using traditional methods. Flexible, semirigid, and bioresorbable materials that are difficult to process through traditional means can be produced by the 3D printing technique.

3.2.4.2 Fast design and production

3D printing is low-cost and fast at producing manufactured parts, allowing for individual design modifications to be efficiently completed.

3.2.4.3 Minimizing waste

This fabrication technique can reduce wastage production, and less scrap is produced compares to conventional methods. It also reduces the cost of material usage. Despite many promising benefits, there are some disadvantages to the 3D printing technique.

3.2.5 Disadvantages

3.2.5.1 Limited materials

Despite 3D printing being able to produce parts in a selection of metals, synthetic polymers, and biopolymers, the available selection of raw materials remains limited. This is due to the fact that not all materials can endure 3D printing as the 3D printing process may alter the properties of raw materials and end-products.

3.2.5.2 Post-processing

3D-printed parts need some form of finishing. The purpose of finishing is to remove support material and to smooth the surface to complete the finished product. Generally, finishing methods include chemical rinsing and air or heating drying. Post-processing may affect the properties of end-products. Despite allowing rapid production, the entire manufacturing process's speed can be slowed down by post-processing.

3.2.5.3 Large volumes

Conventional techniques like injection molding can produce large volumes for mass production, which may be more cost-effective. 3D printing is more suitable for customized products.

Chiesa and coworkers developed a bioresorbable, super-stretchable, and self-adhesive piezoelectric device from a 3D printing technique that sensed

the motility whenever it was applied onto the phantom intestine and hand gesture by signal translation. The device is made of regenerative silk (RS), tannin from chestnut (T), and graphite nanoplatelets (GNP). The 3D-printed grids are illustrated in Fig. 3.9. It is promising for use in gastrointestinal tract motility monitoring and for motility disorder diagnosis.

Bioresorbable segmented poly(ester-urethanes) (SPEU)-glass ceramic scaffolds were fabricated using the FDM printing technique (Lores et al., 2022). The printed scaffold showed high dimensional accuracy.

Dave and coworkers reported the 3D-printed composite of PLA and carbon quantum dots scaffold fabricated via the FDM technique (Dave and Gomes, 2022). The developed scaffolds were photoluminescent. They could be used as alternatives in renewal, restoration, rejuvenation, and monitoring of tissues.

The bioresorbable stent is a medical device that has undergone continuous development processes. 3D printing technology has attracted a good deal of interest for the development of stents. Fig. 3.10 shows the available commercial bioresorbable stents.

Currently, PLLA is most regularly used in bioresorbable stents (Jinnouchi et al., 2019). Bioresorbable poly(p-dioxanone) (PPDO) was combined with PLLA to fabricate artery bioresorbable stents via the 3D-printing technique (Lu et al., 2022). The stents were improved in hydrolytic stability and endothelial cell growth.

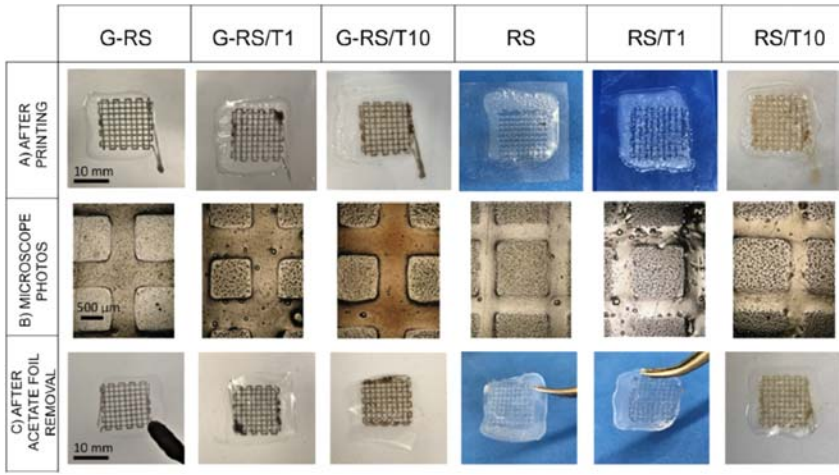

Figure 3.9 Physical appearances of 3D-printed grids. (a) Photographs taken as soon as printing ended. (b) Photographs taken with a brightfield microscope. (c) Photographs of the specimens after acetate foil removal. *(Reproduced from Chiesa et al. (2022).)*

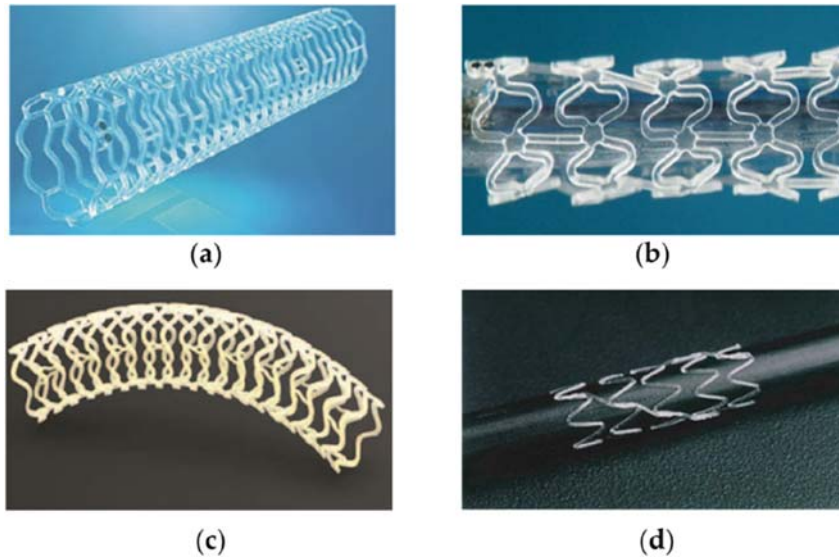

Figure 3.10 Examples of bioresorbable stents: (a) Abbott ABSORB stent; (b) DESolve stent; (c) Fantom stent; and (d) Igaki-Tamai stent. *(Reproduced from Wang et al. (2021).)*

Qiu and coworkers developed a bioresorbable stent from polycaprolactone (PCL)-sulfated chitosan via a 3D printing technique. Their results suggested that the fabricated stents could potentially be used for coronary artery disease. The 3D printing method is shown in Fig. 3.11.

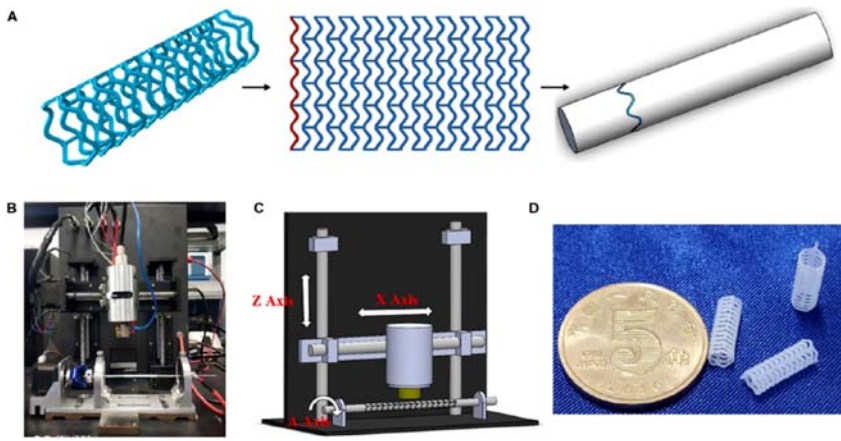

Figure 3.11 (a) Illustration of a 3D-printing process. (b) 3D-printing machine. (c) 3D-printing machine components. (d) Examples of 3D-printed PCL stents. *(Reproduced from Qiu et al. (2020).)*

Yu and coworkers developed personalized bioresorbable airway external splints from polycaprolactone (PCL) via a 3D-printing method. The device could provide functional support for at least 6 months in patients. No complications such as infection or device erosion occurred. The device remained intact throughout the follow-up period. Hence, the device is considered to be nontoxic, reliable, and practical. A personalized 3D-printed bioresorbable airway external splint is shown in Fig. 3.12. Patient-specific external airway splints with a "C"-shaped lumen were designed in SOLIDWORKS. The designed splints were processed by a selective laser sintering system (SLS). This technique can create layer-by-layer custom-made splints following the complex shape and 3D contours of the trachea.

In order to obtain better clinical outcomes for a bare stent, a nitric oxide-eluting hydrogel coating has been developed (Chen et al., 2021). The hydrogel consisted of gelatin and alginate. The hydrogel was applied onto the stents by a dip-coating process. The dip-coated stents could specifically promote the adhesion of endothelial cells along with inhibited smooth muscle cells. In vivo studies in leporine and swine models showed that the developed stents suppressed inflammation as well as promoting endothelium restoration.

Another case of the surface modification of a bare stent was a copper-incorporated polydopamine (PDA) top coating (Li et al., 2022). In vivo studies in rabbit abdominal aorta showed favorable clinical outcomes as well as prolonged structural durability of the stents.

Radiopaque bioresorbable stents with strong X-ray visibility were fabricated by a 3D-printing technique (Ding et al., 2022). Iodixanol was

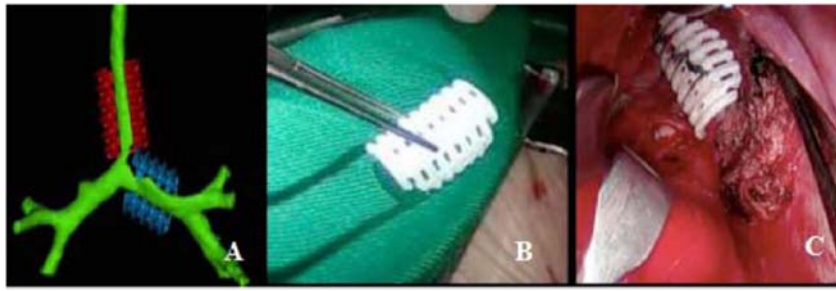

Figure 3.12 (a) Design of a customized 3D-printed airway external splint. (b) The physical appearance of the 3D-printed bioresorbable airway external splint. (c) Intra-operative placement of the splint overlying the malacia tracheal segment. *(Reproduced from Yu et al. (2022).)*

incorporated into citrate-based polymer to make radiopaque ink for 3D printing. The prepared stents appeared to be highly biocompatible in vitro. The stent visualization enabled less invasive follow-up monitoring.

The 3D printing of bioresorbable stents of PLLA and poly(lactic-co-ε-caprolactone) (PLCL) composite was studied by Chausse and coworkers (Chausse et al., 2023). The stents were found to be unaltered by ethylene oxide sterilization.

Sophisticated smart stents integrated with wireless pressure sensor have been developed (Park et al., 2019). These complicated forms of stents were fabricated via a 3D-printing technique, and the stents were made of PCL. The devices efficiently measured intravascular blood pressure in a rat model.

Heart disease in children is different from that in adults to some extent. Zhao and coworkers developed bioresorbable stents for pediatric patients with coronary artery disease (Zhao et al., 2021). The stents were the composites of polycaprolactone-poly(*p*-dioxanone). They showed a suitable degradation rate for vascular remodeling and the healing process.

PLGA and PLA were fabricated as tubular urethral stents via a 3D-printing method (Jaworska et al., 2022). PLGA stents were found to be more stable in an artificial urine.

Aside from stents, the diced cartilage grafts of bioresorbable PCL were successfully shaped with the help of a 3D-printing technique (Canli et al., 2022). The printed grafts were produced into the desired complex shapes which were helpful for utilization in operations such as nasal reconstruction and orbital floor fracture repair.

A bioresorbable composite of PLA and PCL and hydroxyapatite (HA) was developed to provide customized material for bone defect treatment via fused deposition modeling (FDM) (Åkerlund et al., 2022).

3.3 Micro-molding

Micro-molding is a highly specialized fabrication process that produces markedly small high-precision components with micron tolerances. The process starts where a mold is created that has a cavity in the shape of the part desired. Micro-molding is capable of molding more than one material on the same part at the same time. The different materials can be molded together, requiring only one mold cycle. Additives or functional materials can be added during the process.

Microneedles (MNs) are medical devices that have attracted favorable interest in the medical field. They possess microstructures that are spiky and

sufficiently robust for skin penetration. Their application produces a microsized pathway for transferring molecules, including biomedical antigens and cells (Rad et al., 2021). Blood and interstitial fluid can be drawn by this device. Either low- or high-molecular-weight biotherapeutic drugs and vaccines can be delivered through the skin.

Bioresorbable MNs are usually fabricated by micro-molding. Generally, a polymeric solution is poured into the mold. Air voids are removed by vacuum or centrifuge. Molds are then dried, and then MNs are detached after cooling. The micro-molding technique is shown in Fig. 3.13.

Yuan and coworkers developed MNs for diabetic wound healing. The MNs consisted of gelatin-methacryloyl (GelMA) and poly(ethylene glycol) diacrylate (PEGDA). Tazarotene (a wound repair drug) and exosomes were added to the MNs. In vivo studies in diabetic mice showed that the fabricated MNs could promote cell migration and angiogenesis in full-thickness cutaneous wounds. The preparation process and the morphology of MNs are shown in Fig. 3.14.

Yan and coworkers studied two-layered sodium hyaluronate MNs loaded with huperzine powder for Alzheimer disease (AD) treatment. In vivo tests in rats showed that the designed MNs are a promising alternative for AD treatment. A schematic of the preparation process and the morphology of MNs is provided in Fig. 3.15.

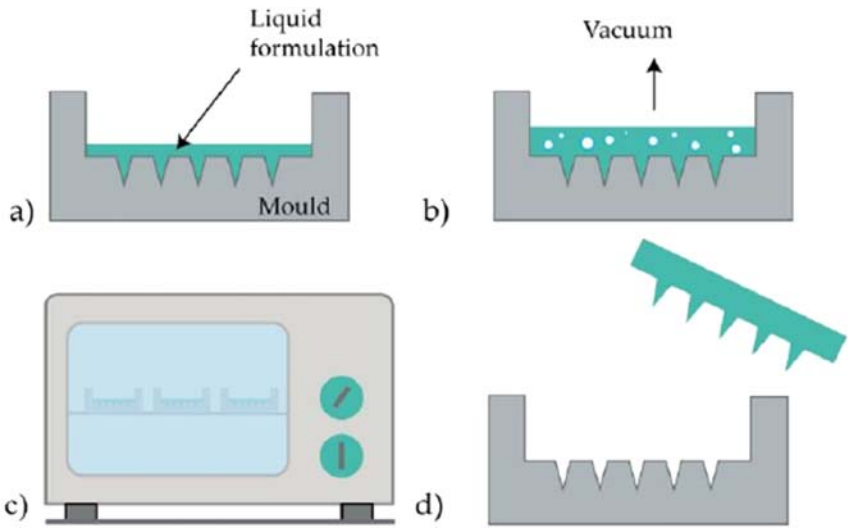

Figure 3.13 MN production using micro-molding: (a) pouring the polymer solution, (b) vacuum degasification, (c) drying, and (d) MNs removal from the mold. *(Reproduced from Tucak et al. (2020).)*

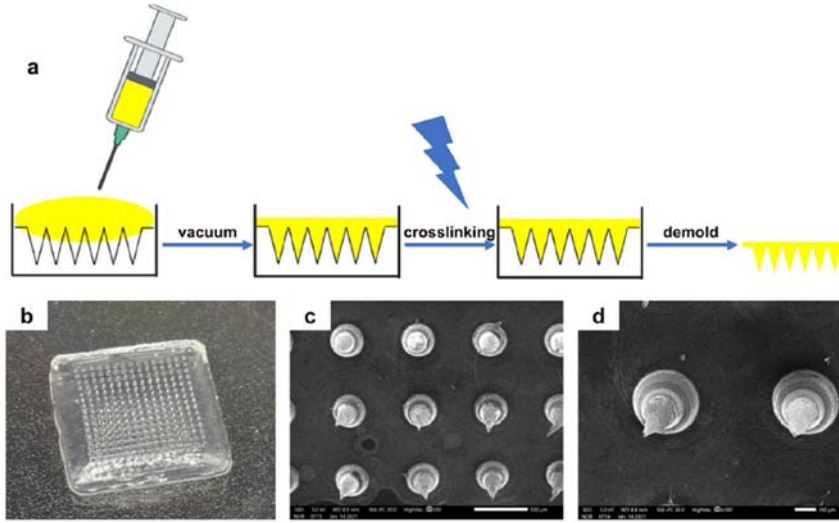

Figure 3.14 (a) Preparation of GelMA MNs. (b) Photographs of an MN patch. (c, d) SEM micrographs of MNs. (c) Scale bar is 500 μm; (d) scale bar is 100 μm. *(Reproduced from Yuan et al. (2022).)*

Integrated stretchable gold-doped graphene microneedles were successfully developed by Lee and coworkers (Lee et al., 2016). The developed microneedles were capable of monitoring sweat-based glucose and pH, along with being thermally activated to deliver Metformin and reduce blood glucose levels in diabetic mice.

A carboxymethylcellulose (CMC) and hyaluronan bioresorbable composite was reported for use in fast-dissolving microneedles for transcutaneous vaccination devices (Ono et al., 2017). These authors found that the developed microneedles were not completely dissolved in human skin. They suggested incorporating a hydration enhancer such as sugar alcohol to speed up microneedle dissolution. Sodium alginate—polyvinyl alcohol (PVA)—polyvinylpyrrolidone (PVP) bioresorbable composite was fabricated into two-layer microneedles for diabetes treatment (Liu et al., 2022).

A sodium hyaluronic acid—sodium alginate—gelatin composite incorporated with curcumin was studied as dual functional microneedles for melanoma treatment and wound healing (Shan et al., 2022).

3.4 Particulate structures

Particulate structures such as nano/microparticles have high surface area homogeneity in size, shape, distribution, and controllable degradation.

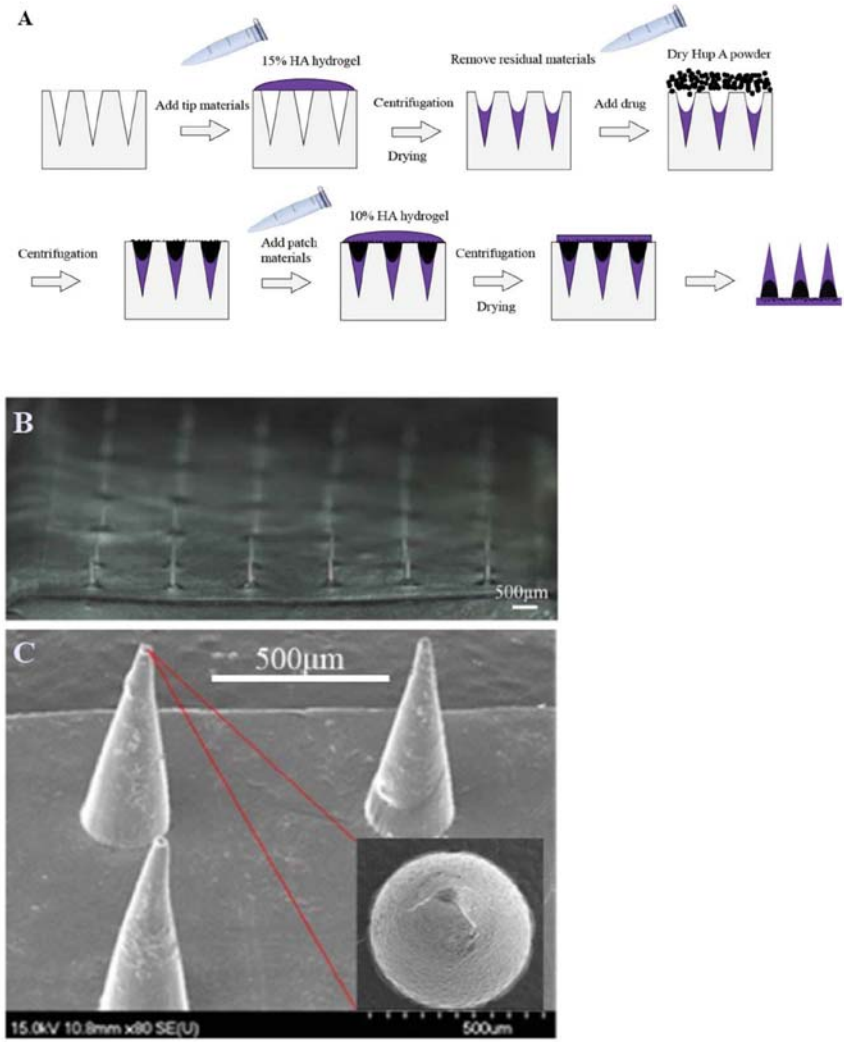

Figure 3.15 (a) Preparation of MNs; (b) the overall appearance of the 6 × 6 DMNP; (c) SEM micrographs of the MNs. *(Reproduced from Yan et al. (2020).)*

Zareei and coworkers developed bioresorbable and super-stretchable paper-based flexible bioelectronics devices with a mix of micro/nano conductive zinc paste. These devices were found to be promising as a wearable wireless heater for drug delivery (Zareei et al., 2022).

3.5 Conclusion and outlook

Current medical devices have undergone significant development in terms of manufacturing techniques. Materials consideration and processing methods are important for long-term success. A product's functionality depends on selecting and processing methods with mechanical properties for the product to perform as designed. The demand for customized medical devices continues to grow. The choice of fabrication technique depends on the device's properties, design, and function. The accuracy and versatility of 3D printing, combined with other fabrication techniques and patterning methods, are attracting favorable interest from both the research and industrial sectors. The benefit of 3D printing technology is apparent and growing rapidly. It is likely to be one of the crucial technologies driving invention, especially with the growth of tissue engineering, bioprinting, and regenerative medicine. The key benefits for manufacturing are that individual modifications can be made to the desired designs, and the speed at which methods can be amended and printed. Modifications can be made rapidly, and tools can be created to optimize specific functions for specific operative techniques.

4.1 Introduction to biopolymer composites

Bio-based polymers are those polymers which have biodegradable behavior and can be categorized by their different physicochemical properties and biodegradability activity (Pan et al., 2016; Imre and Pukánszky, 2013). Biopolymers can be of synthetic or natural origin, while their biodegradability and biocompatibility enhance their utility in food packaging, biomedical, tissue engineering, structural applications, and more (Kim et al., 2022; Alhanish and Ali, 2023). Different forms of biopolymers include nanocomposites, films, hydrogels, and scaffolds that find use in many biomedical applications (Varma and Gopi, 2021).

Polycaprolactone (PCL) is a type of poly (α-ester) which is hydrolytically degradable as well as highly sensitive to even typical humidity (Geoghegan et al., 2023). PCL is a polyester which is flexible at body and room temperatures because of its melting temperature of around 60°C. PCL has amorphous and crystalline domains and provides many interesting benefits due to its sticky quality (Burg, 2014). PCL has a ring-like structure (Fig. 4.1), is prepared by the ring opening polymerization (ROP) method, and is used for the encapsulation of different drugs for targeted drug delivery and controlled release (McKeen, 2017).

PCL belongs to the aliphatic polymers and is commonly used for tissue engineering, dental implants, orthopedics, vascular grafts, nerve repair, ear implants, etc. in the medical sector (Ulery et al., 2011). It exhibits natural breakdown processes within the human body over time (Dias et al., 2022).

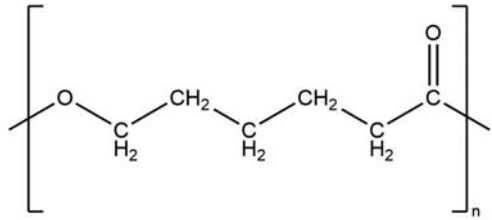

Figure 4.1 Polycaprolactone (PCL) structure. *(Reproduced with permission from Elsevier from McKeen (2017).)*

This property is particularly helpful for its utilization in temporary support or scaffolding in tissue engineering (Scaffaro et al., 2016). PCL is also acknowledged for its biocompatibility nature which means that it does not induce any adverse effects when interacting with biological systems (Álvarez-Ortega et al., 2021). PCL possesses a semicrystalline structure, which contributes to its favorable mechanical properties for utilization in medical applications (Jeong et al., 2018). It has a relatively low glass transition temperature (T_g), rendering it flexible and easily deformable at room temperature (Dell'Erba et al., 2001). PCL also exhibits good elongation, tensile strength, and impact resistance (Peponi et al., 2013). It offers excellent processability and can be utilized in various fabrication techniques, including melt blending, solution blending, electrospinning, and 3D printing (Dwivedi et al., 2020). This versatility allows for the production of PCL-based composites with customized properties and complex geometries, making it suitable for specific medical applications (Patrício et al., 2014). PCL displays hydrophobic properties, which are beneficial for medical purposes, particularly as a drug carrier that necessitates controlled release of hydrophobic drugs. The hydrophobic behavior of PCL enables encapsulation and also the sustained release of drugs (Ahmad Shariff et al., 2023).

4.2 Development and synthesis of PCL

The synthesis of polycaprolactone can be done by either of condensation of 6-hydroxycaproic acid or ROP of ε-caprolactone (Cama et al., 2017), both of which are discussed below.

4.2.1 Polycondensation

Polycondensation is a successive reaction, where two molecule groups can rejoin, resulting in the synthesis of a polymer and often producing a

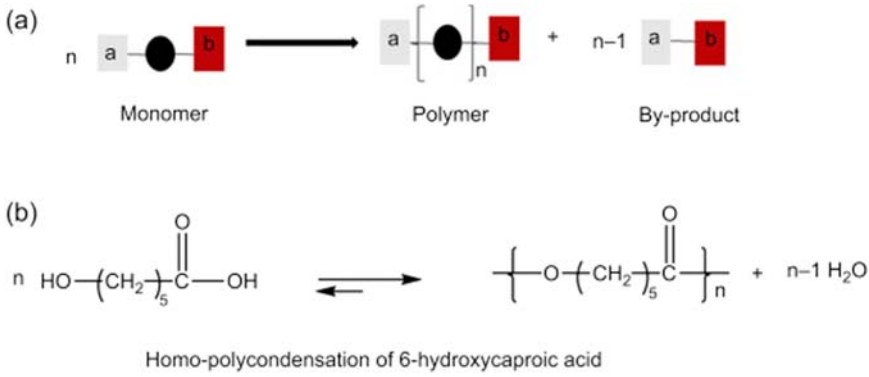

Figure 4.2 Polycondensation reaction for PCL synthesis. *(Reproduced with permission from Elsevier from Cama et al. (2017).)*

low-molecular-weight by-product as a result (Mousavifard et al., 2023). The increasing polymer chain of 6-hydroxycaproic rejoins with other molecules, while the alcohol group in a polycondensation reaction (Fig. 4.2) of PCL, releases water as a by-product and an ester bond is formed (Kaluzynski et al., 2022). This method is rarely used for synthesis of PCL as compared to ROP which results in inflated molecular weight with low polydispersity.

4.2.2 Ring-opening polymerization

ROP is as a chain-growth polymerization where one end of the polymer chain acts as the reactive center for addition of cyclic monomers and forms a longer chain (Cama et al., 2017). The polymer resulting from the reaction encloses end groups that depend on end reactions occurring and an applied initiator. Initiator and catalyst applications can be understood as:

- *Catalyst:* any metallic compound which is used to enhance a polymerization reaction process.
- *Initiator:* amine-alcohol groups that initiate the ROP reaction process.
- *Catalyst initiator:* the first part initiates the reaction of the molecule, while the secondary part catalyzes the reaction. These are used for reactions where only one compound is used.

Depending on the catalyst, the ROP process can be divided into four different processes (Fig. 4.3), each of which has different end groups, polydispersity, and molecular weights (Labet and Thielemans, 2009).

- *Anionic ROPs:* Anionic ROPs are generated during the ROP process, which subsequently attack the carbonyl carbon atom of monomers,

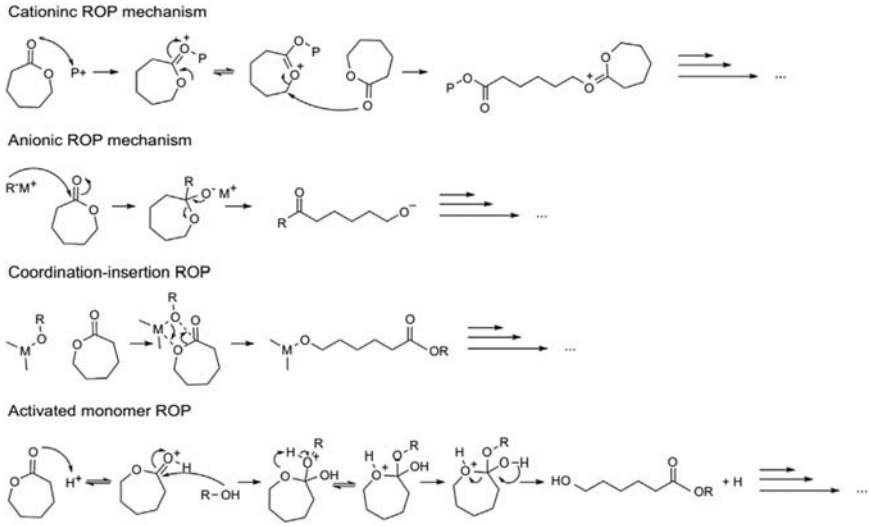

Figure 4.3 Different ring-opening polymerization mechanisms. *(Reproduced with permission from Elsevier from Cama et al. (2017).)*

leading to cleavage of the acyl-oxygen bond along with ring opening (Sudo, 2013; Ageyeva et al., 2018). The occurrence of significant intramolecular reactions is a major drawback, resulting in low-molecular-weight or cyclic polymers, although the effect of this drawback can be controlled at an early stage of polymerization (Penczek and Pretula, 2016).

- *Cationic ROPs:* Cationic ROPs are formed during the ROP process, which are attacked by the monomer's carbonyl oxygen by a bimolecular nucleophilic replacement reaction. Controlling the reactions is a major drawback, while the challenge is to increase the molecular weight (Penczek and Pretula, 2021).
- *Coordination-insertion ROPs:* This involves coordination of the monomer with the catalyst along with the insertion of a monomer through the associated monomer's oxygen—metal bond during propagation in a pseudo-anionic manner (Nifant'ev and Ivchenko, 2019). The alkoxide bond helps in attaching the growth chain to metal during the propagation process.
- *Activated monomer ROPs:* In this type of ROP, a catalyst is associated in galvanizing the monomer molecules, which is further followed by a polymer chain and then it is attacked by an activated monomer.

4.3 Advantages of PCL-based composites in the medical sector

The utilization of PCL composites in the medical sector offers numerous advantages, as outlined below.

4.3.1 Mechanical properties

The incorporation of fillers, such as ceramics and nanoparticles, into PCL can considerably enhance its mechanical properties, which can make it suitable for tissue engineering and load-bearing applications (Yang et al., 2021). In a study of PCL scaffolds, both neat and with chitosan nanofibrils, they were developed using solvent casting, to improve the mechanical properties and cellular compatibility of PCL nanocomposite scaffolds. The findings revealed that the incorporation of chitosan exhibited an important reinforcing effect on the structure, along with noticeable morphological changes. The addition of chitosan positively affects the surface wettability, swelling ratio, and weight loss of PCL, along with improved cell viability, adhesion, and spreading. The proposed PCL/chitosan nanocomposite showed potential for utilization as biocompatible scaffolds for various tissue engineering applications (Fadaie and Mirzaei, 2018).

4.3.2 Biological functionality

PCL-based composites can be modified to have bioactive properties. The cell adhesion, proliferation, and tissue integration can be improved by incorporation of growth factors, peptides, or surface modifications of PCL composites, which can promote tissue regeneration and facilitate the necessary biological interactions for successful medical applications (Dwivedi et al., 2020).

4.3.3 Drug-delivery carrier

The degradation rate can be controlled with the incorporation of specific fillers or additives into PCL. This ability ensures optimal performance and controlled degradation in the body (Liu et al., 2020). PCL-based composites offer flexibility in designing drug-delivery systems. Due to PCL's hydrophobic nature, it is suitable for encapsulating and releasing hydrophobic drugs. The composite material's degradation can be controlled for sustained discharge of therapeutic agents, enabling targeted drug delivery and improved therapeutic outcomes (Homaeigohar and Boccaccini, 2022).

4.4 Applications of PCL in different medical sectors

PCL and its copolymers, namely poly(lactide-co-ε-caprolactone) (PLCL) and poly(glycolide-co-ε-caprolactone) (PGCL) are the most commonly used in the medical sector, particularly for bone growth, vascular implants, fracture fixation, dental treatment, etc. (Zhang et al., 2021). PCL is mainly used as an additive for resins, hence improving their properties including impact resistance (Niaounakis, 2015). The common applications of PCL and its polymers (Fig. 4.4) are summarized in the following subsections.

4.4.1 Tissue engineering

Tissue engineering is a process for regenerating damaged tissues by designing 3D scaffolds that copy the natural extracellular matrix along with cell attachment facilitation (Chan and Leong, 2008). PCL polymer composites recently have gained attention for utilization as scaffold materials because of their biocompatibility (Dong et al., 2021a). In one study, the electro-spinning technique was used to fabricate the PCL scaffold. The prepared scaffolds were then examined for stem cell growth that can be further used for maintenance and generation of many tissues. The investigation revealed that 15% w/v PCL has higher stem cell growth, which also confirms its suitability for repairing soft tissues along with its regenerative medicine applicability (Jabur et al., 2017). Some PCL-based composite application models on animals for wound repair and tissue regenerating are tabulated in Table 4.1.

A study by Ajmal et al. investigated a composite fabricated by the incorporation of quercetin and ciprofloxacin hydrochloride in to PCL-gelatin by an electrospinning method, whereas nanofibers exhibited an average diameter of 725.943 ± 201.965 nm. The scaffolds exhibited antibacterial behavior when exposed to *Staphylococcus aureus* along with antioxidant properties. Gelatin/ciprofloxacin-hydrochloride/quercetin

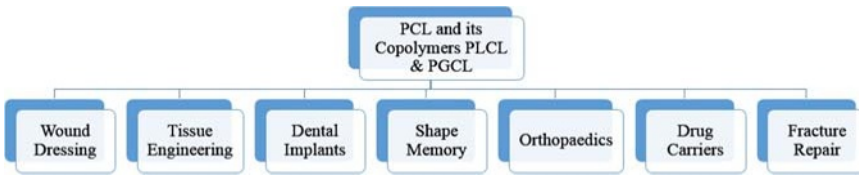

Figure 4.4 Common application fields of PCL and its copolymers.

Table 4.1 PCL composite applications.

Polymers blended with PCL	Animal model	Results
Gelatin (gel)	Balb/c mice	Hybrid nanofibers were created using a two-nozzle electrospinning method, with incorporation of cellulose nanocrystals. The addition of cellulose nanocrystals improved the tensile strength and modulus of the nanofibers by 60% and 80%, respectively. The incorporation of cellulose nanocrystals exhibited a 25% rapid degradation of scaffolds. Meanwhile, the scaffolds exhibited better wound-healing capabilities
Chitosan (cs)	Balb/c mice	Chitosan, lidocaine hydrochloride, and mupirocin were combined with PCL to create scaffolds. Mupirocin discharge was sustained, as well as indicating effective antibacterial properties. The investigation results confirmed collagen deposition, which leads to enhanced wound repairing
Gum tragacanth	Rats	The fabricated scaffolds demonstrated remarkable mechanical strength. Mesenchymal stem cells exhibited adhesion and propagation, promoting tissue regeneration. After 15 days, the scaffolds facilitated re-epithelization and collagen formation. Consequently, these engineered nanofiber scaffolds hold promise as a potential approach for the treatment of diabetic ulcers, particularly in wound healing
Polyethylene glycol	Male Wistar rats	3D nanofibrous fabricated scaffolds, having larger pore size and greater porosity compared with 2D mats made of PCL-PEG-PCL, were used. The porous structure of 3D nanofibrous scaffolds improved water storage and absorption properties. The results confirmed the ability of 3D nanofibrous scaffolds to promote cellular adhesion and migration as well as their importance in wound-repairing applications

Continued

Table 4.1 PCL composite applications.—cont'd

Polymers blended with PCL	Animal model	Results
Polyvinyl alcohol	Female minipig	In this study, PCL was incorporated with PVA polymers to develop the scaffolds. The investigation results confirmed its suitability for wound repair application with minimized scarring

Reproduced with permission from Raina et al. (2022).

incorporation improved the hydrophilicity and biodegradation speed. The scaffold exhibited good biocompatibility as confirmed by hemocompatibility and fibroblast viability tests. The scaffold promoted complete wound healing within 16 days while regulating hydroxyproline and superoxide dismutase, and suggesting its potential application for wound healing (Ajmal et al., 2019). In tissue engineering, the incorporation of bioactive agents into PCL during composite development is very important for improving cellular reactions, tissue regeneration, and scaffold performance. Growth factors regulate the cellular activities and propagation (Yun et al., 2010). Controlled discharge of growth factors from the PCL-composite scaffold offers bioactive indications which influence cell behavior and tissue reconstruction (Goonoo and Bhaw-Luximon, 2019).

In another study, synthesized L-lysine-coated magnetite (Lys@Fe_3O_4) was incorporated into PCL polymer to produce a tissue scaffold for liver cells. The nanoparticles of Lys@Fe_3O_4 were 7 nm in diameter. The incorporation of Lys@Fe_3O_4 reduced the hydrophobicity along with increasing the tensile strength of the developed scaffold. The cell sustainability on the developed scaffolds was increased by 150% compared with individual PCL scaffolds over the 3-day examination. This presence of magnetite nanoparticles helped in faster cell attachment and growth. The investigation results confirmed the usability of the incorporation of Lys@Fe_3O_4 nanoparticles in improving the physical, chemical, and biological characteristics of the PCL scaffolds regarding liver tissue engineering (Rezaei et al., 2021).

4.4.2 Drug-delivery application

PCL polymers provide a favorable platform for the development of drug-delivery carriers because of their biocompatibility and biodegradability nature, which also support a safe interaction with living tissues (Kurakula et al., 2021). Several drugs, including hydrophobic and hydrophilic compounds, proteins, and nucleic acids, can effectively be encapsulated with PCL polymer composites. Biopolymer composites have supported and contributed to the pharmaceutical and medical sectors in multiple applications, with drug delivery being one of them (Wróblewska-Krepsztul et al., 2019). Excipient material fabricated from PCL for drug delivery exhibits characteristics such as low toxicity, biodegradability, durability, and renewable nature (Prabu et al., 2021). In one study, a gelatin-PCL-based composite was evaluated for pore size distribution and thermodynamic property, and the behavior was studied for customized drug delivery. SEM analysis showed that an increase in PCL concentration reduces the porosity of the developed composite (Kanungo et al., 2015). The drug discharge profile (Fig. 4.5) showed that the steady-state phase was delayed with PCL concentration. Also, the composite drug release was at a slower rate as compared to pure gelatin.

In another study, coaxial techniques were used for constructing an NP (nanoparticle) Ag-chitosan/PCL composite as a dual-drug-delivery carrier. The chemical composition, morphological test, and mechanical and thermal analyses were investigated. Study outcomes confirmed the practicality

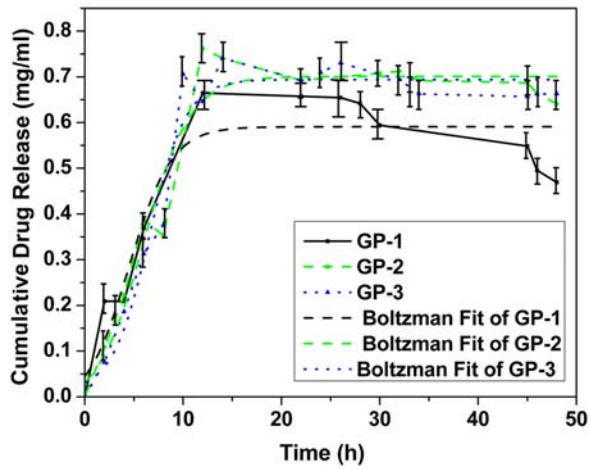

Figure 4.5 Drug-release profile of a gelatin–PCL composite at 310 K. *(Reproduced with permission from Elsevier from Kanungo et al. (2015).)*

of a dual-drug carrier for wound-dressing/healing along with tissue regeneration (Mohamady Hussein et al., 2021). Investigation of the diblock copolymers fabricated from poly-ethylene-glycol (PEG) incorporated with PCL included examination for various usage applicabilities, which revealed that PEG was responsible for enhancing the biocompatibility and PCL promoted the decay of cargo complex. The prepared NPs can be effectively used for targeting tumor cells with less toxicity to normal tissues (Behl et al., 2020). Another study by Faraji et al. investigated the impact of quercetin (Q) on the properties, antimicrobacterial behavior, and cell sustainability of electrospun scaffolds made from a combination of PCL and graphene oxide (GO). NIH/3 T3 fibroblast cells confirmed greater viability of 95% and durable attachment to the scaffolds. Among the scaffolds, the one with the highest quercetin release (0.5% GO/PCL and 43% Q/GO) exhibited approximately 70% released over 15 days as well as a confirmed 50% reduction in bacterial growth after 12 h, indicating the effectiveness against bacteria along with wound repair performance of GO/Q within the PCL nanofibers (Faraji et al., 2020). Furthermore, due to their low degradation polymers, they can also be applied for anticancer drugs for long-term delivery.

4.4.3 Wound healing/dressing

In one study, PCL/oregano oil/gelatin scaffolds were developed via an electro-spinning method to investigate their applicability in wound dressing. XRD, FESEM, and FTIR characterization were examined for the scaffolds, as well as cytotoxicity, antimicrobial, mechanical, and antioxidant properties, which were also studied. Cross-linking of the scaffolds were done using glutaraldehyde vapor to avoid suspension of gelatin at body temperature. The results revealed that increasing incorporation of oregano essential oil (OEO), increases the fiber diameter from 229.6 to 377.03 μm, and also the antibacterial activity, along with higher antioxidant activity. With these enhanced properties, PCL/oregano oil/gel scaffold has been confirmed and supported in its utility for the best wound dressing material without cytotoxicity (El Fawal et al., 2021). A human skin cross-section representation and the phases involved in wound healing are illustrated in Fig. 4.6.

Biopolymers and their composites can be used on skin due to their biodegradable and biocompatible nature. Biopolymer composites are used as hydrogels and healing compounds such as antioxidants, antiseptics, antimicrobials, and growth factors including in inhibitory agents, for accelerating and promoting the process of wound repair

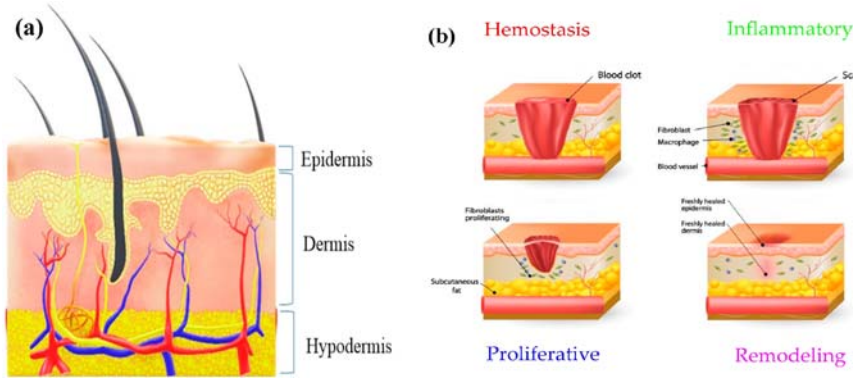

Figure 4.6 (a) Cross-section view of human skin and (b) the wound-healing phases. *(Reproduced with permission from Gobi et al. (2021).)*

(Suarato et al., 2018). A novel composite drug-eluting suture, commonly used as a medical device for wound closure, based on keratin, chitosan, polyethylene glycol (PEG), and PCL, was fabricated by the technique of hot-melt extrusion (Deng et al., 2021). Different tests for physiochemical characterization, drug release, and cytotoxicity were performed on the prepared suture and the results illustrated that the prepared PCL-based composite was a useful application for wound healing.

In one study, wound bandages were designed based on cerium nanoparticle (CeNP)-loaded chitosan/PCL on a cotton fabric surface, wherein the cotton acted as the supporting layer for hydrogel. The prepared hydrogel bandages illustrated antibacterial properties even at low temperatures, with a slower rate of releases. The results from one study suggested that Ce-CS/PCL could be a promising material for scar prevention and wound closure (Dong et al., 2021b).

In another study, copper oxide nanoparticles (NPs) infused PCL/gelatin nanofibers (NF) were fabricated for antibacterial dressing of wounds (Karuppannan et al., 2021). The prepared NFs had dimensions in the range of 130−160 nm and were investigated for biocompatibility and antibacterial activity with the help of MTT assay and disk diffusion assay, respectively. The NFs did not exhibit any bacterial activity in opposition to wound pathogens, including both Gram-negative and Gram-positive bacteria; also the nanofibers exhibited mechanical competence, hydrophilicity, and support for fibroblast growth and attachment. Biocompatibility tests revealed that prepared the NFs were non-cytotoxic and also enhanced its spreading and proliferation.

Table 4.2 Degradation and weight loss performance of PCL polymer and PCL composites.

Matrix	Weight loss (%)	Degradation time (days)
Poly-capro-lactone	4	28
(Poly-capro-lactone)/ 20% (bioactive glass) and 6 wt.% SIM	40	
Poly-capro-lactone	18	30
(Poly-capro-lactone)/ 6 wt.% ZnO	42	
Poly-capro-lactone	0	14
(Poly-capro-lactone)/ gelatin	15.5

The degradation behavior of composites is an important factor in wound healing, therefore is taken into considerable account. The PCL and its incorporated composites' degradation behavior are tabulated in Table 4.2.

4.4.4 Implantable medical devices

Suitable functioning of the skeleton and proper gliding between bones is regulated by articular cartilage. Less surface friction, shock absorbance, and load bearing are the functions of articular cartilage, which depends on collagen type II and proteoglycans. When a degenerative condition occurs, this cartilage has less self-repair capability, for which tissue engineering is used. Starch-polycaprolactone (SPCL) scaffolds offer a substitute to the restoration of cartilage (GOMES et al., 2008).

PCL/hydroxyapatite composites were synthesized by dispersion of hydroxyapatite particles into PCL with different weight percentage for which hydroxyapatite was derived from eggshell waste (Trakoolwannachai et al., 2019). FTIR/XRD tests were examined to investigate the composite's structural characteristics. Furthermore, thermos = gravimetric analysis revealed that the composite formed had a higher thermal stability of up to 300°C and increased melting temperature as compared to PCL alone. Morphology tests were carried out to show the presence of hydroxyapatite on PCL surface and the composited revealed a lower percentage of degradation and higher swelling behaviors. An innovative approach for the fabrication of PCL 3D scaffolds was introduced (Xu et al., 2021). The fabricated scaffolds consist of hierarchically and interconnected structured

macropores of sizes about 300 μm, and increased and high porosity of around 96.4%. SEM results illustrated that the PCL nanofibrous mats have random nanofibers that are overlaid and have diameters ranging between 200 nm and 1 μm. The prepared samples showed good ductility with no shattering or fracturing during compressive tests.

Oral diseases caused by inflammation due to pathologies can result in destruction of the periodontium (tooth-supporting apparatus) that leads to tooth loss. Dental tissue engineering is widely used for treating these pathologies, for which PCL is widely being studied and used in dental implants. An electrospinning method was used for fabricating PCL/PLA and zeolite-based nanofibers, and their efficiency on human dental pulp stem cells (hDPSCs) was studied (Mohandesnezhad et al., 2020). The prepared powders were studied for their morphology by FE-SEM (field emission scanning electron microscopy) examination, and phase formation was studied by XRD analysis. The fabricated scaffolds were investigated by FTIR analysis for the presence of functional groups. The results revealed that the feasibility of hDPSCs on prepared scaffolds was enhanced over 1, 7, and 14 days, and a cell viability increment was observed after 3 days. The prepared nanofibers loaded with zeolite were the most preferred and suitable for both tissue and bone engineering applications.

In an investigation, a nanocomposite coating of PCL/fluoride-substituted-hydroxyapatite (FHA) on Ti_6Al_4V substrate via sol—gel was studied as a biocompatible, bio-active, and non-cytotoxic coating for dental implant application. The consequence of FHA content on the hydrophilicity, morphology, surface roughness, corrosion behavior, and adhesion strength of the coated specimen was also studied and evaluated for cell vitality and bioactive potential. The outcomes revealed that the fabricated nanocomposite coating over the substrate improved its electrochemical, physical, and biological properties such as bioactivity, surface roughness, better cell adhesion, and higher corrosion resistance (Ansari et al., 2020). With all these enhanced properties, this nanocomposite coating could be used for applications in dental implants.

A ring-like inculcated device encapsulated by an antibacterial agent for implants was studied and evaluated. Calcium-alginate hydrogels and PCL, biodegradable and biocompatible polymers, enclosed with metronidazole for agent delivery at the implant site were used for making scaffolds. The high content of PCL in the formulation of the composite ring helped in minimizing the effects of burst release and providing a carrier for release of metronidazole over a time period of 30 days (Lan et al., 2013).

Wall fractures are related to the repair of fractured bones for which orbital implants are needed. The current most commonly used materials for this are associated with some complications such as exposure and migration over time, infections, hemorrhage, and inflammation. PCL emerges as a biodegradable and hydrophobic polymer with some characteristics that are beneficial in fracture repair, such as reduced degradation rate, less reaction to foreign bodies, greater flexibility. and sufficient mechanical strength. A three-dimensionally printed PCL mesh was developed (Kim, 2019) and a study was carried out on patients with wall fracture surgery. The PCL mesh was manufactured by the multi-head method of deposition with the use of 100% PCL and sterilized with gamma irradiation. For evaluation of surface characteristics, porosity, and microscopic morphology of the PCL mesh, FESEM (Fig. 4.7) was used, and molding and bending simulations were carried out to evaluate the biochemical properties. This study found that a PCL mesh leads to outstanding aesthetic and functional outcomes and is an effective and suitable alternative to the bioresorbable implants used for orbital wall fracture reconstruction.

Grafting of bone is a surgical course of action that restores bone with a material. Bone grafting is categorized as allogenous, autogenous, xenogenous, synthetic, or artificial, of which artificial and synthetic grafts are the most popular. PCL is the most studied and preferred polymer because it is economically viable, and has beneficial mechanical properties and a slower degradation rate. A study was carried out on encapsulated melatonin in PCL which emerges as a promising and effective graft material for bone regeneration. an electro-spraying process was used for synthesizing

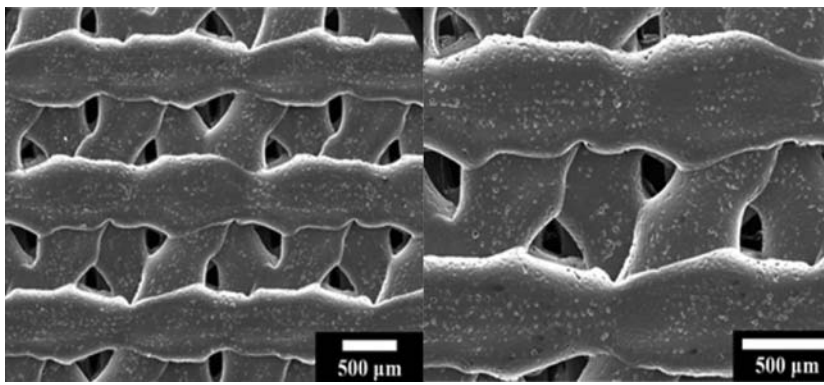

Figure 4.7 SEM images of PCL mesh. *(Reproduced with permission from Elsevier from Kim (2019).)*

microparticles of melatonin and PCL. The findings of this study indicated that bone remodeling is supported by encapsulated melatonin in polycaprolactone and is a very promising and favorable material for synthetic grafts (Gurler et al., 2019).

Different concentrations of trans-anethole (TA) were loaded on polyvinylpyrrolidone (PVP)/PCL fibers with the help of an electrospinning technique (PranavKumar Shadamarshan et al., 2018). Material and physiochemical characterization were done for the developed fibers. Incorporation of TA to the fibers exhibited 0% effectiveness for protein adsorption, swelling, biomineralization, degradation, and thickness of the fiber. The results showed that TA helps in supporting in vitro osteoblast differentiation, which aids in the regeneration and repair of bone tissue.

Another study aimed at improving the characteristics of PCL for tissue engineering by investigating the use of dimethyl sulfone ($DMSO_2$) as a composite with varying concentrations by weight (10%, 20%, and 30%) and was examined for thermal, hydrophilicity, mechanical, and degradation behaviors. The results revealed that the inclusion of $DMSO_2$ enhanced the hydrophilicity and mechanical strength of the composites compared to pure PCL. Increasing the $DMSO_2$ concentration resulted in a reduction in the water contact angle, indicating improved hydrophilicity. Additionally, the composite having 30% $DMSO_2$ exhibited a degradation time 18 times more rapid than that of pure PCL (Jang et al., 2023).

4.5 Challenges and future of PCL in the medical sector

Control over the degradation behavior of PCL-composites has become an important challenge (Malikmammadov et al., 2018). To overcome this challenge, future investigation is required of the variation in properties through fillers, additives integration, and surface modifications (El Yousfi et al., 2023; Ilyas et al., 2022). The incorporation of bioactive compounds improves the bioactivity for tissue regeneration (Lee et al., 2014; Ashammakhi et al., 2022). Scalability, along with cost optimization, is needed for practical application (Molina et al., 2021). Collaboration among researchers, doctors, and medical industries and patients is essential for correct feedback analysis regarding medical product developments. Advanced unconventional synthesis techniques are highly desirable to achieve customized and optimized results (Dalton et al., 2013).

4.6 Conclusion

This study comprises a comprehensive overview of PCL-based composites and their applicability in the medical sector. The characteristics of PCL such as biocompatible behavior, biodegradable nature, and mechanical strength make it suitable for medical applications. PCL polymers have confirmed acceptability in the healthcare sector, with benefits of customizable designs, controlled bio-degradation, and release of drugs. PCL polymers and associated composites also support in tissue/cell integration, adhesion, and proliferation. PCL composites successfully provide therapeutic healing and enable ease of fabrication using electrospinning and 3D printing techniques. However, challenges are related to optimizing recently investigated results for better medical treatment.

5.1 Introduction

In clinics, biodegradable polymer materials are already often employed. Their molecular weight, polydispersity, crystallinity, degradation, and thermal transition all play a significant role in determining their characteristics. The principal synthetic polymers that degrade into natural substances include PCL (polycaprolactone), PLA, PGA [poly(glutamic acid)], polyanhydrides, poly(glycerol sebacate), polyurethanes, and a few synthetic hydrogels (Liu et al., 2020). Electro-spun fibers that are biodegradable and biocompatible have garnered a lot of interest recently due to their numerous medicinal uses. The most promising and extensively researched polymeric biomaterials are PCL and PLA (Liao et al., 2012). Poly-L-lactide (PLLA) is an aliphatic polyester that is known for its biodegradability. It is considered to be the most favorable material for fracture repair because of its relatively high strength and moderate rate of deterioration (McKeen, 2017). However PLLA has some drawbacks, including acidic breakdown products, a low degree of hydrophilicity, and a low compressive strength. The in vivo degraded acidic monomers were discovered to have a negative clinical effect in that they may trigger allergy or inflammatory responses (Balla et al., 2021). PLA has several industrial applications such as in packaging and textiles, and it has also become an important component in bioengineering (Fig. 5.1).

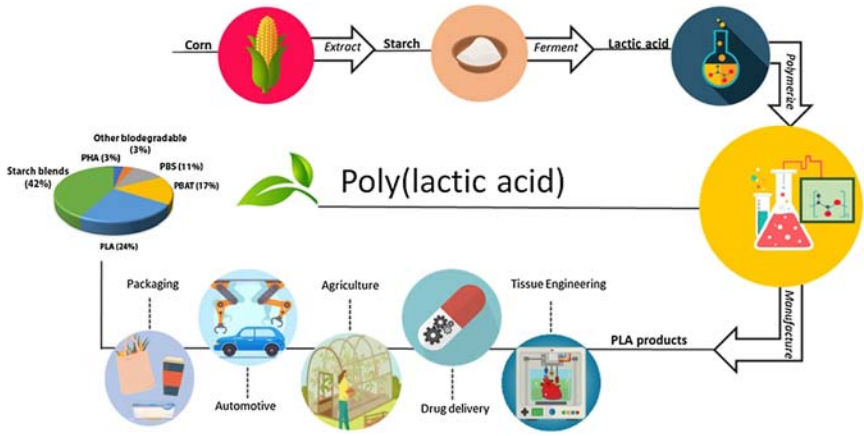

Figure 5.1 PLA and PLA-based composites processing and usability potential overview. *(Reproduced with permission from Balla et al. (2021).)*

The chemical moderation of PLLA, together with blending and copolymerization modification, has been thoroughly investigated as a means of overcoming the aforementioned shortcomings (Wan et al., 2014). In physiologic settings, PLA, a natural intermediary in the metabolism of carbohydrates, can degrade to lactic acid due to its superior biocompatibility and mechanical qualities. Orthopedics and oral and maxillofacial surgery have both employed medical equipment constructed of PLA in clinical settings, including as bone screws (Zhao et al., 2017). PLA can be produced through two main methods, the first is direct polycondensation of lactic acid, while the second is chain-growth or ring-opening polymerization (ROP) of lactide. Lactide is a cyclic ester formed by the di-cyclization of lactic acid (Fig. 5.2) (Augé et al., 2023).

Both PLA and its thermoplastic properties are biodegradable. Applications in orthopedics, cardiology, and dentistry are just a few examples of relevant medical fields. Because of the inherent properties of PLA, 3D-printed constructions may be manufactured quickly and effectively. Advantages of PLA include its ease of production, environment-friendliness, biocompatibility, recyclability, and more, with no toxic or carcinogenic effects. Wheat, carbon dioxide, rice, and corn are a few examples of renewable resources which could be processed to make PLA. Therefore, its by-products are not toxic to the environment or humans. Compared to polymers made from gasoline, PLA requires 25%–55% less energy to make. The low cost and extensive availability of the basic ingredients contribute to the ease of making PLA. The direct contact of PLA with biological fluids has also been permitted by the FDA

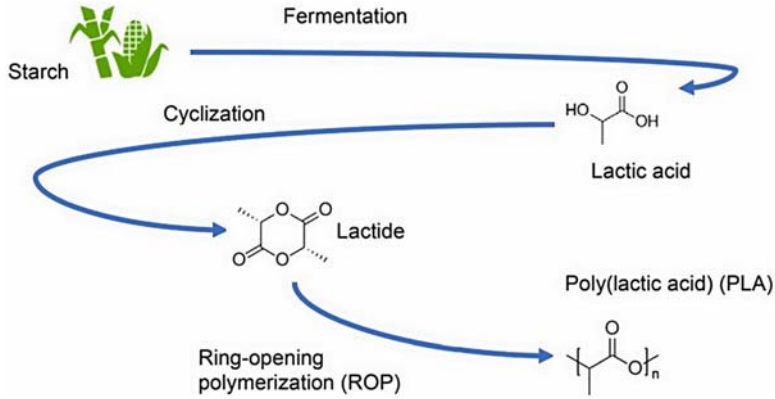

Figure 5.2 Chain-growth polymerization of PLA. *(Reproduced with permission from Augé et al. (2023).)*

(Destefano et al., 2020). PLA and PLLA exhibit a biodegradable nature, which has been gaining major attention for medical device applications (Neumann et al., 2017). PLA/PLLA is a derivative product of sustainable sources such as corn starch and sugarcane, which offers it several advantages, including biocompatibility and sustainable environmental impact, resulting in growing importance in the medical devices field (Farah et al., 2016).

5.2 The chemical structure and synthesis of PLA/PLLA polymers

The chemical structure of PLA/PLLA is important in determining the properties and behavior of by-products. PLA is a rectilinear aliphatic polyester composed by lactic acid units, while PLLA is a stereoisomer of PLA, consisting exclusively of L-lactic acid units (Fig. 5.3) (McKeen, 2012).

The organization of lactic acid monomers within the polymer chain impacts the crystallinity, mechanical strength, and degradation behavior. Additionally, PLLA properties are influenced by the L-lactic acid to D-lactic acid ratio, thus it is important to be considered for controlling the material characteristics for specific medical applications. Several synthesis methods are available to develop PLA/PLLA polymers. Direct condensation polymerization involves the lactic acid monomers reaction, and ROP utilizes lactide. Meanwhile, melt polymerization involves the linear polymerization of lactide in the molten phase. Each synthesis method has its advantages and limitations. Exploring these different synthesis techniques provides acknowledgment of their impacts on the PLA/PLLA polymer properties (Lopes et al., 2014).

5.3 The physical and thermal characteristics of PLA/PLLA polymers

The physical properties of PLA polymers are important factors to be considered for their use in medical applications. The related physical properties found in the literature are discussed in Table 5.1.

The various nanoparticle incorporations affect the PLA properties, which are discussed in Table 5.2.

The thermal properties of PLA/PLLA polymers such as the glass transition temperature (T_g), melting temperature (T_m), crystallization, and thermally stable behavior have an important role in their processing, shaping, and medical applications (Teixeira et al., 2021; Cheerarot and Baimark, 2015). T_g is responsible for the polymer undergoing the transition from a glassy state to an elastic state. This transition significantly impacts the flexibility as well as processability of the polymer (Xie et al., 2020). T_m reveals the temperature at which the polymer melts and can be molded, while the crystallization behavior affects the strength and crystallinity (Kulkarni, 2022). Additionally, thermal

Table 5.1 Physical characteristics of PLA.

Characteristics	Values
Specific gravity	1–1.5
Surface energy (dynes)	36–40
Melting temperature (°C)	140–210
Molecular weight (Daltons)	Approx. 1.6×10^5
Melt flow index (g/10 min)	4–22
Crystallinity (%)	5–35
Glass transition temperature (°C)	50–75
Solubility parameters ($J^{0.5}/cm^{1.5}$)	21

stability indicates the polymer's resistance to degradation at higher temperatures. At high shear, PLA remains a non-Newtonian pseudoplastic fluid. Rheological models such as the Carreau–Yasuda model and Cross-WLF model were followed to study the rheological properties of PLA. Thermodynamics refers to the investigation of energy transport and conversion. Understanding the workability of PLA requires an understanding of its rheological and thermal characteristics (Liu et al., 2020). At room temperature, PLA is a rigid polymer. T_g commonly lies between 55°C and 65°C, while T_m having

only an L/D-isomeric arrangement lies from 160°C to 170°C. Its low melting temperature in comparison to poly(ethyleneterephthalate) (PET) highlights one of PLA's primary limitations in creating acceptable applications. PLA properties may be improved by changing the distribution and ratio of L/D isomers along with alteration of the melting points for the lowest at 130°C and the highest at 220°C (Farrington et al., 2008).

5.4 PLA/PLLA-based composites fabrication methods

It is necessary to properly acknowledge the co-relationship between PLA characteristics along with their reinforcement (fibers, additives, nano- and micro-fillers, etc.) for adaptability and degradation effects (Fig. 5.4) (Murariu and Dubois, 2016).

5.4.1 Additive manufacturing

Various additive manufacturing techniques are available for general PLA/PLLA-based composites development, , and of these some are widely used, such as fused deposition modeling (FDM), stereo-lithography (SLA), and selective laser sintering (SLS) (Kafle et al., 2021). Pharmaceutical items are frequently made via 3D printing which is a computerized process that has vital applications for individualized dosage medication because of its low cost and precise free form. FDM, SLS, SLA, direct ink writing, polyjet, and digital light processing are the most common 3D printing methods currently in use for the medical sector. PLA has a wide temperature range for hot extrusion (Azad et al., 2020). Prior to FDM printing, drug components are frequently incorporated with polymer filaments as there is relatively less capability of drug loading by FDM (Quodbach et al., 2022).

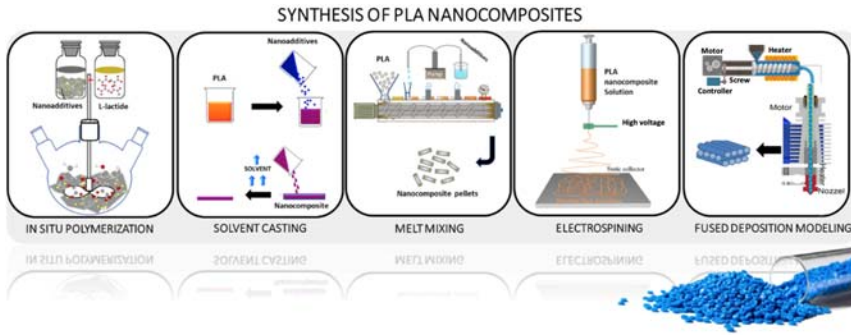

Figure 5.4 PLA composites fabrication methods. *(Reproduced with permission from Bikiaris et al. (2023).)*

Medication discharge properties of FDM-produced tablets may completely be modified based on the form, polymer used, and drug payload (Tan et al., 2018).

5.4.2 Solvent-based methods

Solvent processing delivers an alternative method for shaping PLA/PLLA-based composites. This method involves dissolving PLA/PLLA polymers in an appropriate solvent and afterward shaping and solidifying the composite resulting in the formation of thin films (Sousa et al., 2019). Electrospinning, another solvent-based technique, offers the advantage of controlled porosity, surface morphology, and mechanical properties (Casasola et al., 2014; Bambole and Yakhmi, 2016). The processes of pore creation during electrospinning mostly comprises temperature, and humidity with phase separation.

5.4.3 Melt compounding

Melt processing methods are usually followed for PLA/PLLA-based composites because of their simplicity, versatility, and cost-effectiveness. They involve melting the PLA/PLLA polymer and integrating reinforcing additives. This mixture can be extruded into desired shapes (De Santis and Pantani, 2015). Another widely used melting technique is the injection molding method, where the molten polymer is injected through a mold. On the other hand, blow molding is also used sometimes to produce hollow-type assemblies. In a study investigating the effectiveness of plasticizers collected from renewable sources, specifically epoxidized palm oil (EPO) and epoxidized soybean oil (ESO), on PLA, the results illustrated that EPO was more efficient at lower concentrations, while ESO exhibited higher effectiveness for greater concentrations of 10 wt.% and 15 wt.% with significant enhancements in impact strength and processing efficiency for PLA. Additionally, EPO and ESO indicated their suitability as alternatives to traditional plasticizers in the PLA processing industry (Tee et al., 2014).

5.4.4 Miscellaneous methods

Hybrid/miscellaneous processing methods combine different techniques to overcome limitations. Hybrid processing offers new possibilities for advanced PLA/PLLA-based composites in medical device applications. Low-pressure microcellular injection, rotary jet spinning, melt extrusion, tube drawing, melt blending, solvent casting, etc. are some of the methods that can be used for the production of PLA-based composites.

5.5 Biocompatibility and biodegradability of PLA/PLLA composites

The biocompatibility and biodegradability of PLA/PLLA composites are important considerations in medical applications. Studies of the biocompatibility and degradation behaviors of PLA/PLLA composites are described next.

5.5.1 Biocompatibility

The biocompatibility of materials indicates the capability of a composite to cooperate with human tissues without causing infection or toxicity. PLA/PLLA exhibited excellent biocompatibility, which makes them suitable for various medical applications. The biocompatible nature of composites ensures their safe and effective use inside the human body (Yoon et al., 2017). Multiple factors influence the biocompatibility of PLA/PLLA composites, including their chemical structure, surface characteristics, degradation products, and interactions with biological systems. For evaluating cytotoxicity, hemocompatibility, and tissue response along with cell feasibility inspection, blood compatibility tests are crucial to ensuring the biocompatibility of PLA composites (Pawar et al., 2014).

5.5.2 Biodegradability

Biodegradability refers to the degradation behavior over time through natural processes. PLA/PLLA are biodegradable in nature and undergo hydrolysis when exposed to water. The biodegradation behavior of PLA/PLLA composites exhibits a significance role for temporary medical devices and implants that must be absorbed or replaced (Narayanan et al., 2016). PLA/PLLA composite degradability is influenced by various factors including the molecular weight of the polymer along with its composition, processing techniques, as well as environmental conditions, etc. Meanwhile, the addition of reinforcement fillers and additives can also influence the biodegradability of PLA/PLLA composites (da Silva et al., 2018; Naser et al., 2021).

5.6 Applications of PLA/PLLA composites in the medical sector

PLA/PLLA have undergone increased consideration as important probable materials for medical applications. This study investigated recent case studies that reveal the effective medical applications of PLA/PLLA-based composites.

5.6.1 Scaffolds for tissue reengineering

PLA/PLLA-based composites are extensively used as scaffolds for tissue reengineering. PLA-based composites offer a 3D assembly that enables the growth of cells along with tissue regeneration. The mechanical characteristics of PLA composites are customizable as per the targeted tissue requirements. Additionally, the biodegradability of PLA enables its steady replacement by natural tissue over time.

The crystallinity of PLLA, which ranges from 37% to 42%, depends on the processing variables and molecular weight. This polymer has a melting temperature of around 175°C and T_g ranging between 60°C and 65°C. Also, PLA/PLLA have high tensile properties and elongation, along with superior bioresorbability and biocompatibility, which makes them perfect for applications that bear loads such as the closure of wounds, sutures, controlled-release systems, tissue culture, and orthopedic fixation (Sheikh et al., 2015). The addition of functional nanoparticles to the PLA matrix increase its physical properties with alterations in its surface properties. They are useful in artificial bone regeneration and tissue engineering (Mohammad et al., 2016). In the in vitro testing of a novel biocomposite polymer, PLLA augmented with short phosphate glass fibers (PGFs), showed PGFs' presence to have a rapid osteoinductive influence for a 3-week duration, without compromising the mechanical capabilities over an 8-week timeframe (Melo et al., 2019). The typical semicrystalline PLLA produced by compression molding exhibited peaks on an XRD diffraction test (Fig. 5.5).

New 3D-printed shape-memory PLLA-TMC/GA-TMC scaffolds having superior mechanical characteristics and degradability for bone tissue engineering have been created and examined for physiochemical properties

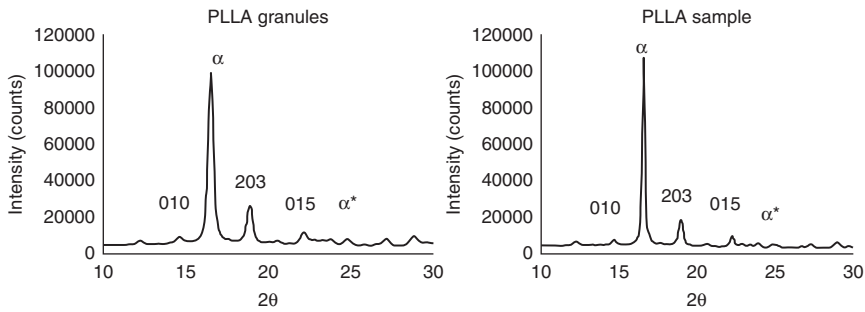

Figure 5.5 Exhibited XRD diffraction arrangements by PLLA granules and a PLLA specimen. *(Reproduced with permission from Melo et al. (2019).)*

and confirmed their potential for future use in the clinic for the repair of bone defects (Hu et al., 2023).

PLA/Kef-based hybrid scaffolds coated on electrospun fibers via air-plasma treatment have vast applications in skin tissue engineering (Lopresti et al., 2021). The reinforcement action of a Kefiran coating was mechanically analyzed by a tensile test. Morphological and gravimetric analyses were used to evaluate the water resistance of the prepared coating at 37°C, which clearly indicated that the solubilization of PLA fibers coated with Kefiran was faster than for P-PLA (pretreated PLA) fibers. The in vitro experiments conducted demonstrated the important promise of the PLA-Kef hybrid scaffold for applications in skin tissue re-engineering (Lopresti et al., 2021). In another study, composite scaffolds were prepared via FDM technology by PLA and n-HA (nano-hydroxyapatite) for bone muscle manufacturing (Wang et al., 2021). The optimization of prepared scaffolds was done by mechanical test, material characterization, a and stem cell biocompatibility test. The proposed composite for study was found to be highly printable, with good mechanical strength, and the biocompatibility was much higher compared with neat PLA scaffold. Thus, the prepared n-HA-PLA scaffold proved to be a good and promising material for the repair of large bone defects.

Pisanti et al. examined the scaffold microstructure effect on human mesenchymal stem cells (hMSCs). PLLA scaffolds were created using SC-CO_2 gel drying, resulting in nanostructured scaffolds. Porogen leaching led to the formation of microporous scaffolds, characterized by mean pore sizes measuring 100, 250, and 500 μm. The results revealed the successful attachment of hMSCs on all scaffolds, with greater proliferation in the 250 and 500 μm pore size scaffolds in the bioreactor, and the 100 μm pore size scaffolds in the static culture (Pisanti et al., 2012). Another research work investigated PLLA scaffolds and the effects of pore size on cultured human articular as well as nasoseptal chondrocytes. The feasibility, attachment, morphology, and extracellular matrix production were evaluated. Both types of chondrocytes confirmed feasibility, while the smaller pore sizes facilitated chondrocyte distinction. The thermally induced phase separation (TIPS) method was utilized to produce homogeneous scaffolds with specific pore sizes, preserving the chondrocyte phenotype. A minor difference in pore size affected the expression of

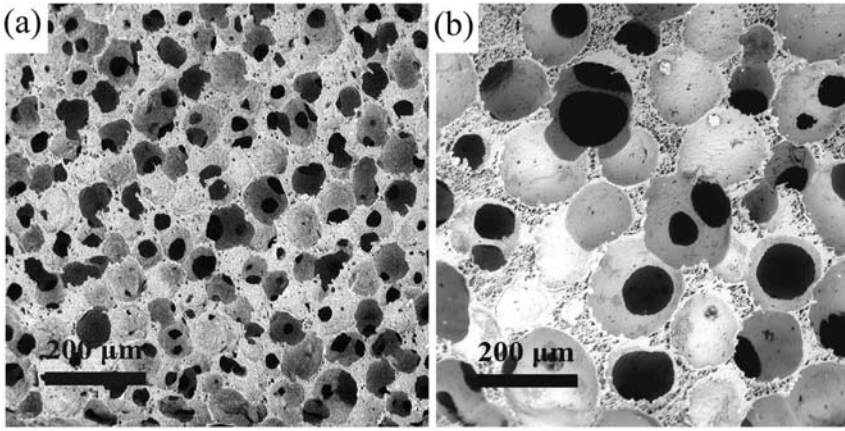

Figure 5.6 SEM images of a PLLA scaffold: mean pore dimension (a) 100 μm and (b) 200 μm. *(Reproduced with permission from Conoscenti et al. (2017). Scale bars 200 μm.)*

cartilage markers, with 100 μm pores stimulating chondrogenesis in PLLA scaffolds (Fig. 5.6) (Conoscenti et al., 2017).

5.6.2 Stent development

PLA/PLLA-based composites are useful in cardiovascular medical devices including stents and vascular grafts. Controlled degradation behavior by PLA composites reduces the associated risk of future difficulties related with permanent implants (Naseem et al., 2017). A study has investigated the surface-modified magnesium hydroxide nanoparticles (nMH), synthesized by nucleophilic addition reaction (nGTMH) and ROP of DL-lactide. The results revealed that the modified nMH incorporated into PLLA composite exhibited higher Young's modulus. The modified nMH confirmed low cytotoxicity, antiinflammatory properties, greater albumin/fibrinogen ratio, reduced platelet activation, as well as excellent hemocompatibility. The investigation concluded that the use of surface-modified nMH as an additive showed potential in enhancing the composite's mechanical/biological characteristics for medical purposes, particularly for vascular stents and orthopedic implants (Kang et al., 2020).

While metallic stents are helpful for avoiding acute occlusion with lowered late restenosis following coronary angioplasty, thrombosis and restenosis remain major issues. Bioresorbable stents had been developed

with benefits such as 100% bioresorption and mechanical flexibility. Many materials are now being studied for the construction of biodegradable stents, with PLLA and magnesium being the most favorable and promising. The process parameter effects over physical characteristics have been explored in order to create a PCL/PLA polymer tube for stent requirements (Guerra et al., 2017). The results demonstrated that polymer concentration and withdrawal speed have a considerable impact on the tube characteristics. PLA and PCL exhibited limited opportunities as stent materials during DMA testing and degradation analysis, while the PCL/PLA composite tube demonstrated favorable behavior for stent requirements.

Another study of biodegradable stents made from a self-reinforced poly-L,D-lactide copolymer (SR-PLA 96) in double-helical spiral structure was evaluated for its appropriateness in ureteral stenting. Temporary kidney function changes were observed in a few cases with SR-PLA 96 and C-Flex stents. Kidney washout times were prolonged in pigtail-stented ureters but remained normal with SR-PLA 96 stents. Renal function was confirmed as normal after ureteral repair with SR-PLA 96 stents. The results exhibited the potential use of SR-PLA 96 stents for ureteral repair (Lumiaho et al., 1999).

5.6.3 Drug-delivery systems and orthopedic implants

PLA/PLLA-based composites have established effective applications in orthopedic implants, including plates, screws, and anchors. These implants offer impermanent structural support during the healing practice and steadily degrade as new bone tissue develops (Amini et al., 2011). The integration of Mg particles into PLLA may have a favorable biological impact on bone repair. The alkaline environment created by magnesium breakdown could counteract the damage caused by acidic by-products of PLLA, resulting in inflammation relief (Chandra and Pandey, 2020). In one study, two composites, Mg/PLLA and MgF_2/PLLA, were developed by extrusion and injection molding. The impact of Mg inclusion was investigated as well as degradation and cytotoxicity being assessed for prospective use as orthopedic implants. The results illustrated that cell survival was improved by 37% when the amounts of MgF_2 and Mg were raised along with a suitable degradation rate, which confirms that magnesium incorporation has a significant capability for orthopedic transplant use (Wan et al., 2014). In another study on Mg-PLA composites, the in vitro breakdown as well as bio-mineralization were studied. The findings showed that the degradation of Mg particulates effectively

countered the acidic nature of PLA, along with controlled degradation behavior based on the quantity of Mg particulates (Zhao et al., 2017).

PLA is a thermoplastic polymer having an elevated elastic modulus, and low elongation at the tensile and break strength. Compared with other thermoplastics in commercial industries, PLA exhibits higher brittleness and lower overall strength as well as its processing properties also being less favorable, including susceptibility to hydrolysis along with a relatively slow crystallization rate (Ramlee and Tominaga, 2019; Li et al., 2023). PLA's stereochemical structure and physical characteristics can be easily adjusted by modifying the ratios of monomer feed, adjusting the stereochemistry of monomers, and optimizing polymerization conditions (de França et al., 2022; Worch et al., 2019). Because of their proclivity to rupture when the programming stains approach 10%, the shape-memory effect is often limited to small deformations. To increase the degradability of nondegradable shape-memory polymers (SMPs) for use as resorbable SMP transplants, lactic acid can be incorporated into the polymeric chains (Xu and Song, 2015). the shape-memory effects of PLA-based polymer hybrid have been studied for its glass-transition behavior, mechanical and thermal properties, miscibility, shape-memory property, and phase structure (Zhang et al., 2013). A study of (styrene-butadiene-styrene) SBS/DL-PLA composite was investigated for nontoxicity and biocompatibility of the materials which also has the shape-memory system of dual domain. The composite exhibited that as SBS exceeds 50% by weight for the elastic domain and 30% by weight for the thermo-switch domain, it offered good shape memory for DL-PLA ranging between 30% and 70% by weight (Zhang et al., 2013).

PLA/PLLA-based composites are widely used in drug-delivery applications. The PLA composites have been considered for encapsulating therapeutic agents along with controlled release. A study of four formulations of polylactide-co-glycolide (PLGA) nanoparticles loaded with Tamoxifen citrate (TNPs) were conducted. TNPs loaded for $27.16\% \pm 2.08\%$ w/w confirmed significant drug loading with sustained-release ability, and efficient uptake by breast cancer cells in the laboratory. The results indicated that the formulation exhibited breast cancer treatment qualities, with potential drug-loading ability (Maji et al., 2014). In another study, novel nanocomposites were fabricated by incorporating PLA-nanofibers with tetraheptylammonium-capped Fe_3O_4 magnetic nanoparticles for improving the growth of daunorubicin medicine over the cancer cells. The results showed improved interaction and accumulation of daunorubicin and subsequent cancer cell death (Lv et al., 2008).

5.6.4 Surgical tools/meshes developments and dental materials

PLA/PLLA-based composites can be used as surgical meshes for hernia repair and soft-tissue reinforcement. Compared to nondegradable meshes, PLA composite exhibits higher biocompatibility and reduces the associated long-term complication risks (Davachi et al., 2016). The bone screws developed through injection molding by PLA were improved and simulated by limiting shrinkage and warpage (Davachi et al., 2016). Based on the findings of injection molding simulations, the design of the experiment, along with a structural examination, the investigation confirmed that the composite consisting of 5% PLLA/TC (30% triclosan and 70% PLLA composite) and nano-hydroxyapatite by 5 wt.%, is the best alternative for biomedical applications among others (Davachi et al., 2016).

In another investigation, nanocomposites were fabricated with TiO_2-reinforced PLA matrix by a sonication process (Salahuddin et al., 2019). Encapsulation in PLA of TiO_2 nanospheres after being loaded with norfoxacin (NOR) drug was carried out. Different ratios of TiO_2 in the prepared nanocomposite were studied and evaluated for several morphologies and compared with PLA loading. No changes in the IR peak of NOR were observed, which indicated the absence of chemicals. All the results supported and confirmed the suitability of the prepared nanocomposite as a good alternative regarding tumor cell line carriers and it also exhibited antibacterial behavior which could be used in treating related infections.

PLA/PLLA-based composites have exhibited several applications in dentistry, such as dental implants, bone graft replacements, and guided tissue restoration films. The PLA composites contribute to enhanced dental treatment and reduce any required additional interventions (Cai et al., 2023).

Titanium is a widely used material for dental implant applications because of its constructive biological reaction (Özcan and Hämmerle, 2012). Implant failures resulting in infections remain an important concern (Silva et al., 2022). A study on the release behavior of chlorhexidine (CHX), which possesses broad-spectrum antimicrobial properties, from polylactide (PLA)-coated titanium was investigated. The method involved anodizing commercially pure titanium and subsequently coating over the PLA-CHX. The results showed that using a CHX-containing PLA-coated titanium implant has the probable effect of diminishing bacterial colonization during implant surgery (Kim et al., 2008).

Various PLLA-based composite applications along with reinforcement materials with composite properties are discussed in Table 5.3.

Table 5.3 Various applications of PLLA-based composites.

Application	Composite	Synthesis method	Characteristics
Bone tissue	(Poly-L-lactic acid)/(carbon nanotubes)/hydroxyapatite	TIPS	Young's modulus = 12.5 MPa Mean porosity = 87%
	Poly-L-lactic acid	TIPS + porogen leaching	MP = 97%
	(Poly lactic-co-glycolic acid)/(poly-L-lactic acid)/(poly-D-lactic acid)	Electrospinning	Young's modulus = 1.55 MPa Tensile strength = 2.04 MPa
	(Poly-L-lactic acid)/(poly-caprolactone)	TIPS	Degradation = 3 weeks
	(Poly-L-lactic acid)/hydroxyapatite	Electrospinning	Mean porosity = <90%
	(Poly-L-lactic acid)/hydroxyapatite	Additive manufacturing	Young's modulus = 17.2 −40.8 MPa Mean porosity = >90% Degradation = 24 weeks
	(Poly-L-lactic acid)/hydroxyapatite	Thermally induced phase separation	Young's modulus = 3−5 MPa Mean porosity = >90%
	(Poly-L-lactic acid)/hydroxyapatite	Porogen leaching	Young's modulus = 0.4 MPa
	(Poly-L-lactic acid)/hydroxyapatite	TIPS + porogen leaching	Young's modulus = 37−56.2 KPa Mean porosity = 88−98
	(Poly-L-lactic acid)/(bioactive glass)	TIPS	Young's modulus = 6−8 MPa Mean porosity = 88.5% Degradation = 28 days
	(Poly-L-lactic acid)/(bioactive glass)	Porogen leaching	Young's modulus = 55−81 MPa Tensile strength = 2.7−4.2 MPa Mean porosity = 69%−71% Degradation = 90 days
	PLLA/(poly-caprolactone)/hydroxyapatite	Porogen leaching + freeze drying	Young's modulus = 1−2 MPa Tensile strength = 0.2 MPa Mean porosity = 90% Degradation = 78 weeks

Continued

Table 5.3 Various applications of PLLA-based composites.—cont'd

Application	Composite	Synthesis method	Characteristics
Cartilage tissue	(Poly-L-lactic acid)/(poly-caprolactone)	TIPS	Young's modulus = 90–110 kPa Mean porosity = 93%–95%
	(Poly-L-lactic acid)	Thermally induced phase separation	Mean porosity = 93%
	(Poly-L-lactic acid)/chitosan	Freeze-drying	Tensile strength = 0.3–0.5 MPa Mean porosity = 73–93% Degradation = 28 days
	(Poly-L-lactic acid)/(silk fibroin)	Electrospinning	Tensile strength = 1.5 MPa Degradation = 12 weeks
Blood vessels	(Poly-L-lactic acid)/gelatin	Electrospinning	Young's modulus = 6–20 MPa Tensile strength = 5–7 MPa Mean porosity = 73–75% Degradation = 7 days
	(Poly-L-lactic acid)/(poly-caprolactone)/collagen	Electrospinning	Mean porosity = 20–80%
	(Poly-L-lactic acid)/chitosan/collagen	Electrospinning	Tensile strength = 2.13 MPa
Skin tissue	(Poly-L-lactic acid)/collagen	Freeze-drying	Young's modulus = 43–55 MPa Tensile strength = 5 MPa
	(Poly-L-lactic acid)/gelatin	Electrospinning	Tensile strength = 20 MPa Mean porosity = 72%
	(Poly-L-lactic acid)/gelatin	Freeze-drying	Young's modulus = 41–43 MPa Tensile strength = 5.7 MPa Degradation = 12 weeks

5.7 Future perspectives

The application and usability of PLA and PLA/PLLA-based composites for medical devices has seen growth, and research into future perspectives is required. Unconventional methods such as 4D printing, biofabrication, and nanotechnology aid better material control, and thus need to be explored more. Multifunctional PLA polymers include antimicrobial characteristics that result in allowing complex tissue to be manufactured, and implants need further research to be more precise and optimized.

5.8 Conclusion

PLA/PLLA-based polymer applications for medical devices have revealed favorable developments. Synthesis methods such as melt processing, solvent processing, and additive manufacturing are widely used. PLA polymer composites are biocompatible and biodegradable, which makes them suitable for temporary implants. PLA/PLLA polymers have extensive scope in medicinal/therapeutic applications, such as muscle re-engineering, orthopedics, drug loading/delivery, stent development, dentistry, etc. Challenges include optimizing the constraints and achieving controlled drug release. Advanced research is desirable to improve the mechanical properties and discover new techniques for better patient care.

6.1 Introduction

The development of materials with specific properties allied to the search for sustainability has increased the demand for materials with biodegradable characteristics and low environmental impact in their processing. For medical and pharmaceutical applications, these materials must still be biocompatible and present mechanical properties that meet the needs of each application (Mukherjee et al., 2023). Polyhydroxyalkanoates (PHAs) are good examples of components present in materials with these characteristics, due to their form of synthesis and behavior, and they have increasingly been the subject of research for the optimization of biomaterials (Kalia et al., 2023).

Among the analyzed market forecasts, there is no consensus on the exact market value of PHAs or its growth, but the literature reports values in the range between 80 and 90 million dollars for 2020 and 2021 (DMBR, 2022; GMI, 2022; Marketsandmarkets, 2022). Furthermore, among the analyses, a compound annual growth rate (CAGR) value ranging from 5.4% to 11.5% was reported, with the total market value potentially exceeding hundreds of millions of dollars by the end of this decade or the beginning of the next (DMBR, 2022; GMI, 2022; Stratview Research, 2021; TMR, 2021). This increase is due to the growing demand for bioplastics today, and their renewable properties, such as biodegradability. Although most plastic production still has a fossil origin, the environmental problems associated

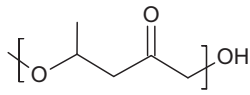
with these sources are also contributing to the endeavor for the development of renewable technologies and products (DMBR, 2022; GMI, 2022).

The market research of Global Market Insights (2022) shows that most PHAs produced are known to have short or medium carbon chains. The main types are PHB, PHBH, and PHBV. The PHB market exceeded, in 2021, the value of USD 20 million, while PHBV has a CAGR exceeding 9% in the forecast for 2030. Europe is the largest market region for PHA, followed by North America, presenting a CAGR of 9.5% in the forecast until 2030, due to European policies related to plastic which in turn drive companies to invest in these bioplastics. However, the Asia–Pacific region has the greatest growth potential in the 2030 forecast, with a CAGR value that exceeds 10%. As for the areas of application, PHA production is widely focused on the food packaging industry, but other sectors have been gaining prominence and showing potential for growth in the coming years. Agriculture, biofuels, and biomedical industries are among the potential applications for PHA. In fact, the biomedical industry is the second largest market for PHA, with a CAGR forecast higher than 9% for the period between 2022 and 2030. The potential increase in this specific field is due to properties such as biodegradability, biocompatibility, and low toxicity, allowing wide application of PHA in technologies such as implants, tissue engineering, drug delivery, etc. (GMI, 2022).

Another market research study brought similar results in terms of market size, with the market cap forecast to reach US$167 million in 2027, thus having a CAGR of 15%. This study also shows that, despite the many factors that influence the growth of the PHA market, there are still barriers that slow down this growth, with the main one being the high relative cost of production compared to conventional plastics, in addition to the production technology still being in the early stages of development (Marketsandmarkets, 2022).

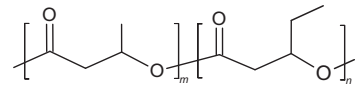
6.2 Polyhydroxyalkanoates (PHA)

Polyhydroxyalkanoates are biodegradable and biocompatible aliphatic polyesters synthesized by microorganisms because of the fermentation of at least 75 different species of bacteria, including *Bacillus cereus*, *Pseudomonas putida*, *Bacillus pumilus*, *Pseudomonas huttiensis*, *Yersinia frederiksenii*, *Aeromonas ichthiosmia*, and *Sphingopyxis terrae*, among others. They are produced intracellularly when there is excess carbon and limitation of nutrients (phosphorus, nitrogen, and oxygen) in the medium. They are produced in



solid form in the cytoplasm of the microorganism, do not dissolve, and can be accumulated in high concentrations. The composition of the synthesized polymer is governed mainly by three factors: the specificity of the enzyme that will synthesize the PHA, the carbon source supplied, and the pathway by which this carbon is metabolized (Kaniuk and Stachewicz, 2021; Wampfler et al., 2010).

PHAs are composed of monomers consisting of 4—5 carbons or 6—14 carbons. The chemical structure and chain size of these polymers allow a division into two main groups: short-chain PHAs are relatively brittle, have high crystallinity and high melting point; while medium-chain PHAs have elastomeric properties, low melting point and low crystallinity (Norhafini et al., 2017; Wampfler et al., 2010).



PHA polymers are isotactic, hydrophobic, water-insoluble, resistant to hydrolytic degradation, and have piezoelectric properties and some resistance to UV degradation. There is a diversity of monomers that make up the structure of PHA, including polyhydroxybutyrate (PHB) and poly-3-hydroxybutyrate-*co*-poly-3-hydroxyvalerate (PHBV). Fig. 6.1 shows some of these short-chain (SCL-PHA) and medium-chain (MCL-PHA) structures.

Polymeric biomaterials offer some advantages in various applications due to their biocompatible and biodegradable characteristics. PHA-based composites have potential medical applications, due to their ability to be broken down after their complete functionality, they can be used in implants, sutures, tissue regeneration, and as drug-delivery systems. When employed in the formulation of drug carriers, PHAs allow for good distribution to target sites and diffusion into cells. For medical applications, when PHAs are isolated, special attention must be paid to contamination by pyrogenic compounds, which are endotoxins (lipopolysaccharides) from the outer cell membrane of some groups of bacteria. Filtration and activated carbon processes can be used to remove these endotoxins (Lam et al., 2017; Wampfler et al., 2010).

Besides biocompatibility, appropriate mechanical properties for each specific application are a key feature for biopolymers in the medical area. For example, in bone treatments of various kinds, the material must possess some properties similar to bone, such as: (1) the ability to permeate the site of the defect; (2) the capacity to induce osteoblasts and other cells to produce bone material; and (3) biodegradability, or the ability to degrade naturally within the organism without inducting inflammatory or other

adverse reactions in the patient (Shishatskaya et al., 2006). Table 6.1 describes the thermal and mechanical properties of some PHA films.

The degradability of PHA compared to polymers of synthetic origin (produced from petroleum) is also an important and attractive property for medical and pharmaceutical applications. Some enzymes are responsible for breaking the molecular bonds of these polymers, using them as a carbon source for their growth. An example is depolymerase, the main degradation enzyme of PHA, which is reduced to monomers and oligomers after being hydrolyzed. The crystallinity of the polymer structures and external factors such as pH, humidity, temperature, and degree of microbial activity influence the speed of degradation of these compounds. The occurrence of PHBV, for example, can affect this process. Under aerobic conditions, PHAs can be fully degraded into water and carbon dioxide, and under anaerobic conditions, they can be transformed into methane by an infinity of decomposing microorganisms (Lam et al., 2017).

Table 6.1 Thermal and mechanical parameters of PHA films.

Samples	Melting temperature (°C)	Glass transition temperature (°C)	Tensile strength (MPa)	Elongation (%)	Elastic modulus (GPa)
P(3HB)	175–180	4–9	40–45	4–5	3.5–3.8
P(3HB-*co*-3% 3HV)	170		38		2.9
P(3HB-co-20% 3HV)	114–145	−5 to (−1)	20–32	27–50	0.8–1.9
P(3HB-*co*-3% 4HB)	166		28	45	
P(3HB-*co*-64% 4HB)	50		17	591	30

Adapted from Kaniuk and Stachewicz (2021).

The polymer production and processing industry has been paying attention to two main points: the reduction in the use of synthetic chemicals in a growing trend toward sustainability, and the end of the life cycle of these products combined with their degradability. In this case, PHA shows more promise in relation to conventional matrices such as polypropylene and polystyrene, for example.

Finally, depending on the requirements for the material to be produced, PHA group polymers can be modified, blended, surface-modified, and combined with inorganic materials to improve their properties and potential use. These combinations can change the polymer structure, affecting its crystallinity, thermal and mechanical properties, and most importantly, its rate of degradation.

6.3 Polyhydroxybutyrate (PHB)

Considering their significant mechanical strength, PHAs also represent an important research subject in orthopedics. In fact, a selection of different types of PHAs, including polymer of hydroxybutyric acid (PHB), copolymers of hydroxybutyric and hydroxyvaleric acids (PHB/PHV or PHBV), and copolymers of hydroxybutyric and hydroxyhexanoic acids (PHB/PHHx) have been demonstrated to serve as matrices in which osteogenic cells can be cultured in vitro (Köse et al., 2003; Deng et al., 2003; Yang et al., 2004; Wang et al., 2004).

The research by Shishatskaya et al. (2006) was among the pioneering works to report the production and characterization of a PHB matrix composite with the addition of hydroxyapatite (HA). HA is a biocompatible material which has some disadvantages, such as high rigidity and low elasticity, and these disadvantages can be tackled by associating the material with less rigid, more elastic polymers. In this sense, traditional fossil-based polymers significantly hinder the biocompatibility of the composite, and thus polymers which occur naturally are preferable for associating with HA. In this study, bacteria were used for synthesizing PHB, and the HA was obtained from bovine cortical bones, configuring a truly biological originated composite. The hybrid composite was fabricated by the mechanical-physical method, involving cold-molding at high pressure and with weight percentage ratios ranging from 10% to 50% HA. The characterization included physical and mechanical properties as well as in vitro and in vivo tests to evaluate the osteogenic characteristics of the composites. When compared to native PHB, the composites displayed the same temperature

properties and crystallinity while possessing a more hydrophilic surface. From an osteogenic point of view, the optimal compositions were those with 10% and 20% HA, which yielded the best growth and differentiation characteristics of murine marrow osteoblasts; these results suggest that hybrid PHB/HA composites are feasible possibilities for bone tissue reconstruction applications.

Other materials can be associated with PHB for producing composite materials, such as, for example, the research concerning PHB/kaolin nanocomposites (Ankush et al., 2022). The solvent casting method was applied in this study to add different contents of polyethylene glycol and kaolin to the PHB matrix. By adding kaolin in contents of up to 10% in weight, the following results were obtained: decrease of the contact angle (representing an improvement in wettability); melting temperature was raised; increased blood clotting time; and surface characteristics, such as protein adsorption, platelet adhesion, and complement activation, were shown to be improved in the nanocomposite. Optimal mechanical properties were obtained for the 10% kaolin sample, similar to those of bone. Finally, in vitro and cytotoxic tests demonstrated the formation of hydroxyapatite on the optimal composition and the safety of biological use of this nanocomposite.

One of the first manuscripts to investigate the feasibility of PHB in biomedical applications was published in 2003 (Volova et al., 2003). The authors compared the in vivo biological reactions of PHB and PHBV sutures in comparison to reactions caused by silk and catgut sutures. In addition to displaying satisfactory strength during the healing period, PHB and PHBV sutures caused a tissue reaction considered usual for foreign-body invasion—and less pronounced than the reaction observed for catgut sutures.

PHB composites are interesting options also as drug-delivery scaffolds, due to their biocompatibility, biodegradability, and piezoelectric characteristics. Recently, Pryadko et al. (2022) reported the production of PHB composites using gelatin and magnetite as components, aiming to obtain magnetoactive scaffolds for biomedical use. The authors described the formation of core—shell-structured composite scaffolds, where PHB acts as the core and the shell is gelatin, where PHB crystallinity is decreased during this process. Additionally, cytotoxicity studies revealed that both human cervix adenocarcinoma cells and primary fibroblasts displayed a cellular response to the scaffolds similar to that of the control sample (pure PHB), indicating the nontoxic characteristic of the composites. Finally, the

saturation magnetization of the scaffolds occurred in a satisfactory range for use as magnetoactive materials, thus rendering these composites as interesting possibilities for wound treatment, tissue engineering, and drug-delivery scaffolds activated with an external magnetic field.

Another interesting characteristic of PHB composites is the ability to conduct electricity, as reported by (El-Hadi and Elbary, 2018). This article describes the fabrication of a blend material containing PHB, poly(-propylene carbonate) (PPC), multiwalled carbon nanotubes (MWCNTs), and plasticizers. PHB, among other biopolymers, has been researched as a promising material for the electronic industry as a matrix with the addition of conductive fillers as an alternative for conductive metals, because these biopolymers can be cheaper, lighter, and display corrosion resistance. Also, this addition enhances the mechanical and physical properties of pure PHB, which is known to be brittle and thermally unstable. In biomedical applications, these biopolymer blends are suitable for use as biosensors, drug-delivery systems, and in tissue engineering. Maintaining fixed contents of plasticizer and PPC, the authors produced blends with varying contents of PHB and MWCNTs via solution casting and posterior melting in a hot hydraulic press. Differential scanning calorimetry results showed that MWCNTs can act as nucleating agents in the PHB matrix, causing an increase in the crystallization rate of the material when compared to pure PHB; however, the blends displayed lower thermal stability than the pure material. Also, MWCNT addition increased the electrical conductivity of the blends which is an interesting result considering practical applications.

PHB can act in composites for biomedical applications as the matrix, but also as the added material to obtain specific properties. Rodríguez-Contreras et al. (2016) aimed to use PHB nano- and microspheres containing antibiotics in association with titanium and poly(ethylene glycol) (PEG) to produce antibacterial implant surfaces. The idea was to minimize postoperative infections that can happen in this type of application. Titanium surfaces were subjected to chemical activation via oxygen plasma or sodium hydroxide, and alkoxysilanes posteriorly to allow for PHB and PEG reactions and forming of covalent bonds. The results of in vitro bacterial tests indicated the attainment of antimicrobial properties in the titanium surfaces for both chemical strategies.

The employment of PHB in surface modification for biomedical applications was reported earlier, in 2011, in research targeted at reducing the corrosion rate of magnesium inside the human body (Ma et al., 2011). This metal ranks as one of the lightest available, and its elastic modulus is close to

the average modulus of human bone. This fact represents an important advantage in implant materials since the similarity in stiffness avoids the occurrence of stress shielding, an undesirable phenomenon in which bone does not heal optimally. In this scenario, the main disadvantage of magnesium is its high corrosion rate in body fluids, limiting the time window of its application. This study sought the development of a poly(3-hydroxybutyrate) coating on the surface of magnesium aiming to reduce the corrosion rate of the material. The authors verified the lower corrosion rate of the PHB-coated magnesium when compared to the pure metal. Additionally, the corrosion process occurred almost uniformly, allowing for possible adjustments of these coatings for specific time periods desired for the material application.

A more recent example of research involving PHB as a composite component for surface coatings was published by Mathina et al. (2022). In this article, the authors describe the importance of PHB addition to promote the biocompatibility of this composite material, which also contains HA from crab shell, aloe vera, and strontium oxide. The material was deposited via electrophoresis on a 316L stainless steel surface, a traditional material used in orthopedic applications. Structural, morphological, antibacterial, and biocompatibility properties assays indicated the potential of this composite coating to enhance the biomedical applications of 316L stainless steel. PHB has also been reported in the literature (Lin et al., 2021) as a promising composite component in addition to poly-epsilon-caprolactone (PCL) in fibrous membranes which can be tailored to be hydrophobic or hydrophilic, depending on additional HCl and NH_4OH treatments.

6.4 Poly(hydroxybutyrate-co-hydroxyvalerate) (PHBV)

Poly(3-hydroxybutyric acid-co-3-hydroxyvaleric acid) is a biodegradable, biocompatible, and nontoxic material produced by bacteria under certain conditions. It is a thermoplastic material, well established as an alternative to nonbiodegradable polymers (Kaniuk and Stachewick, 2021). The PHBV activity is highly dependent on its characteristics, such as the mean size, shape, surface electrical charge, and capacity to interact with proteins (Tebaldi et al., 2019). Due to its properties, several studies evaluating biopolymer suitability for medical and biological applications have been conducted.

One of the main advantages of PHBV is the fact that, just like other PHAs, PHBV is easily modified or combined with other compounds, enabling several different applications (Kaniuk and Stachewicz, 2021). Many studies have reported the combined use of PHBV with other natural polymers, such as gelatin (Meng et al., 2008), keratin (Yuan et al., 2009), polylactic acid (He et al., 2014), and collagen (Liu et al., 2019), among others. Other studies have reported the incorporation of inorganic compounds and mixtures, such as magnetite (Vilos et al., 2013), hydroxyapatite (Karbowniczek et al., 2022), and titanium dioxide (Karbowniczek et al., 2022), generating materials with superparamagnetic behavior.

One of the challenges of PHBV use in medical applications, however, is the fact that this polymer is hydrophobic. This property might affect cell activity, such as cell adhesion, where hydrophilic materials are preferred (Yuan et al., 2009). Most studies described in the literature aim to develop a material with enhanced hydrophilicity, promoting a better environment for cell fixation and growth (He et al., 2014).

Electrospinning has been widely reported as an effective method for obtaining PHBV nanofibers. This method consists of submitting a solution containing the biopolymer to high voltages. The solution is then ejected through a needle, accelerating toward a grounded collector. The solvent is evaporated, and the charged polymer fiber is deposited on the collector, forming a nanofibrous structure (Meng et al., 2008). Several parameters, such as PHBV concentration, the possibility of incorporating other compounds, and the solvents used in the process might affect the results.

Liu et al. (2019) also reported a method for obtaining nanofibrous PHBV-based materials. Forcespinning is a procedure where a polymer solution is ejected from spinnerets at high rotational speeds onto collecting frames, allowing the production of fibers from various materials at higher rates than electrospinning. This method is also cheaper than electrospinning since high voltages are not required.

PHBV can be used to obtain films for medical purposes, such as tissue engineering and wound dressing (Meng et al., 2008). Methodologies described in the scientific literature indicate the obtention of PHBV-based films via solvent evaporation of a polymer solution. However, the usage of nanofibrous materials instead of films may enhance the cell activity, due to the larger surface areas present in the fibers as compared to films. Yuan et al. (2009) could demonstrate how NIH 3T3 cells interacted with different substrates. In the SEM pictures, it is possible to observe how cells were able to adhere and grow at higher rates in fibers than on film surfaces. The

presence of keratin, which enhances biomaterial hydrophilicity, also contributed to cellular activity.

The application of PHBV-based nanofibrous materials is mainly related to structural functions, such as tissue engineering scaffolds and wound dressing. This is due to PHBV biocompatibility, biodegradability, and nontoxicity, which allow it to perform in recovery therapies for different tissues. Inorganic materials can also be incorporated, improving physical properties and developing enhanced materials. Karbowniczek et al. (2022) were able to successfully add ceramic nanoparticles of hydroxyapatite (HA) and titanium dioxide (TiO_2) into PHBV scaffolds. The results showed that the incorporation of HA significantly increased the mechanical properties of the material, while TiO_2 addition reduced these properties. However, the best results were achieved when both nanoparticles were incorporated into PHBV scaffolds. The authors related this behavior to the better distribution presented by hydroxyapatite than that presented by titanium dioxide. In addition, HA formed smaller agglomerations. Larger agglomerations formed by TiO_2 were related to a defect-like behavior in the structure, thus reducing its mechanical resistance. Fig. 6.2 presents the structure of scaffolds of different compositions.

The coating of compounds with magnetic and superparamagnetic activity is also a part of PHBV possible employment. Magnetic nanoparticles have several applications for scientific and clinical purposes. They may be used as biosensors, protein and cell separation systems, and magnetic carriers for hyperthermia and tissue-specific drug delivery (Vilos et al., 2013). An efficient coating of the magnetic material, such as iron oxide (magnetite), is important because, even though it is biocompatible, it is easily cleaned by the body, preventing it from being used in medical applications. The PHBV coating and its lower degrading rate allow the iron oxide to achieve its potential. However, to enhance PHBV coating properties, it is necessary to overcome its hydrophobicity. A possibility is the modification of its surface with a fatty acid, such as oleic acid or lauric acid (Idris et al., 2018). In fact, the surface modification of superparamagnetic iron oxide nanoparticles allowed for better encapsulation with PHBV. The resulting material showed great potential for drug delivery of tetracycling hydrochloride, being able to successfully be loaded with the drug and release it in a diffusion-controlled manner (Li et al., 2016).

Magnetic resonance imaging (MRI) is a nonradiating biomedical imaging technique where gadolinium is currently used as a contrast agent. However, magnetite nanoparticles have been extensively tested as

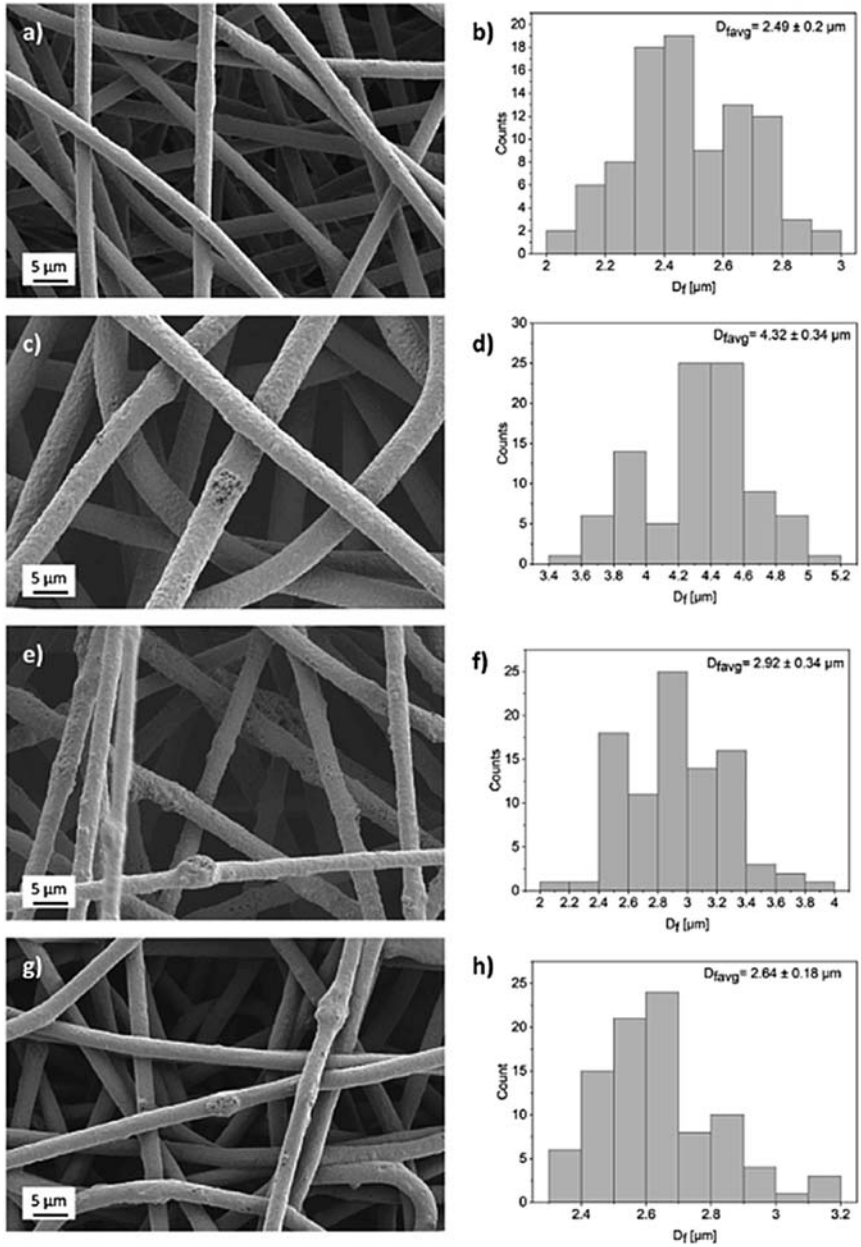

Figure 6.2 SEM micrographs of electrospun nanofiber morphology and corresponding histograms of their fiber diameters: (a, b) PHBV; (c, d) PHBV + HA; (e, f) PHBV + TiO_2; and (g, h) PHBV + HA + TiO_2. *(Source: Karbowniczek et al. (2022).)*

replacements because they present higher magnetic susceptibility among other advantages. In addition, when working with sufficiently small particles, it is possible to orient each particle by using an external magnetic field, causing them to lose their magnetic stability in the process. Changing the magnetization direction several times during a measurement interval will make the measurement zero at zero external fields. This phenomenon is called superparamagnetism. Superparamagnetic particles respond rapidly to an external field, which can be used to heat up the surrounding tissue, thus generating hyperthermia. This behavior shows that nuclear MRI is a promising tool for cancer therapy.

PHBV/PLA multifilament fibers have been also a potential material for medical sutures. He et al. (2014) described the use of the filament for muscular and subcutaneous tissue sutures in rats. No toxic symptoms were noticed at the implantation sites. The presence of inflammation was much less severe as compared to the control sample, a commercial alternative. Signs of polymer degradation started to appear 6 weeks after the procedure. From 12 to 48 weeks, the filament was loosened and lost its bundle structure but kept a uniform diameter. The results showed that PHBV compounds presented superior biocompatibility and its degradation products, such as 3-hydroxybutyrate (3-HB), 3-hydroxyvalerate (3-HV), and 3-hydroxyhexanoate (3-HHx), were completely nontoxic and even beneficial for the growth of vascular smooth muscle cells.

PHBV compounds can also be used as controlled drug-delivery systems. Prodigiosin (PG) is a bacterial pigment with strong anticancer activity. When incorporated into the biopolymer, it affected its thickness, making it more compact, but with a rougher surface and more distinctive topographical features. The primary role of a drug-delivery system is to provide controlled drug release in terms of time and location; at the same time, it should prevent the drug from suffering premature metabolic degradation, increase its bioavailability, and prevent drug availability fluctuation. The PG incorporation in PHBV resulted in film samples with improved physical properties and functionality in comparison with PHBV alone. The treatment with PHBV did not have any effect on cancer cells. However, all samples containing PG exhibited statistically significantly higher anticancer effects. Better anticancer potential was observed with higher concentrations of PG. PG exhibits strong anticancer activity against HCT116, colon cancer cells, according to its concentration. Compounds used in anticancer therapies are usually highly toxic and hydrophobic, so PHAs are suitable carriers for this type of drug-delivery system.

Bacterial pigment PG was successfully incorporated into PHBV. Apart from conferring a lively color to the compound, the incorporation improved not only the biopolymer's physical properties but also its functionality. It has affected PHBV's degree of crystallinity, thermal stability, and morphology. Films were also cytotoxic against cancer cells, indicating that the resulting material might be used in anticancer therapy (Ponjavic et al., 2023).

6.5 Conclusion

PHAs are being consolidated as interesting alternatives to fossil-derived polymers in medical and biomedical applications. Their set of characteristics are very interesting in this scenario, because they combine good mechanical properties with biodegradability and biocompatibility; thus, PHAs are reported in the literature in applications such as sutures, electrically conductive material for composites, bone tissue engineering and drug-delivery goals, fibrous membranes, composite coatings for metallic implants, and finally as components for composite blends aimed at additive manufacturing. The global market displays positive signs, reaching monetary values of up to USD 90 million in 2021 and CAGRs in the order of 9%–10% until 2030. Therefore, this class of biodegradable polymers is expected to experience continuous growth in the next decade and to replace a number of traditional polymers already in use in pharmaceutical, medical, and biomedical applications.

7.1 Introduction

Loss of tissues and organs to injuries and degeneration caused by chronic diseases are the most prevalent challenges in modern medicine. Although common, conventional treatment approaches such as removal of damaged tissues/organs, replacement and regeneration via grafting, transplants, and biomedical implants have several obvious drawbacks, including donor accessibility, probable immuno-induced rejection of implants/transplants, poor compatibility, implant vulnerability, poor integration, and ethical/religious issues, among others (Francis et al., 2023; Hajebi et al., 2020; Saska et al., 2021). This often leads to loss of life or a significant reduction in health-related quality of life. A better therapy option with fewer risks is to replace or rejuvenate damaged tissues by utilizing biocompatible platforms that can sustain cell development or contain living cells (Hajebi et al., 2020; Naseem et al., 2022; Saska et al., 2021).

Tissue engineering (TE), a multidisciplinary field that integrates engineering, chemistry, and biology, has emerged as an alternative to traditional methods of treating damaged tissues (Capuana et al., 2022; Emily Hartley et al., 2022; Hetal Patel et al., 2011). Herein, 3-D structures that support cell growth are used. These structures, called scaffolds, are designed to imitate the extracellular environment while providing mechanical support, promoting cellular growth and proliferation by fostering cell adhesion and

All rights reserved.

movement, and aiding the diffusion of nutrients and products and overall tissue development (Capuana et al., 2022; Duan et al., 2022). Scaffolds are generally made from biocompatible biomaterials (Hetal Patel et al., 2011). However, advances in the mechanistic understanding of the interactions occurring in the extracellular matrix and the need to avoid secondary surgical operations to remove temporary implants have led to increased demand for materials that can be tailored to suit specific needs. These needs include biodegradability, in vivo resorption, compatible elastomeric properties, etc. (Duan et al., 2022; Kennedy et al., 2023)

Bioresorbable polymers have emerged as a special class of biodegradable and biocompatible materials that can be tailored to meet the current needs of TE scaffolds (Hajebi et al., 2020; Mahdavi et al., 2017). Bioresorbable polymer scaffolds (BPSs) can be tuned to undergo mediated hydrolytic or enzymatic degradation to form nontoxic products that the body can eliminate via excretion or metabolic pathways (Afshar et al., 2022; Mendibil et al., 2019). The emergence of BPSs has led to a reduction in the number of surgeries required during tissue regeneration and reduced use of suppressant drugs (Chew et al., 2017; Tawade et al., 2022).

As polymers, the synthesis of BPSs typically involves the use of chemical or physical methods. Herein, traditional techniques such as extrusion, injection molding, among others are dominant. However, the increasing need for tailoring to suit specific applications and cellular environments, high sensitivity of some bioresorbable polymers to traditional techniques, etc. have prompted the emergence of newer techniques such as electrospinning, 3D and 4D printing, and lithography (Kirillova et al., 2021; Saska et al., 2021). The selection of an appropriate bioresorbable polymer and fabrication technique is crucial to successful tissue regeneration, as properties of scaffolds are dependent on the choice of material and fabrication technique. This chapter offers an overview of the traditional and current methods of synthesizing BPSs and areas of application. The influence of fabrication technique on the area of application and degradation of the polymers are emphasized. Future perspectives on the synthesis and applications of BPSs are also discussed.

7.2 Synthesis of bioresorbable polymers

The synthesis of bioresorbable polymers for scaffolds involves a combination of contemporary materials science and biomedical engineering techniques to produce polymers with specific characteristics that can be tailored

to a broad range of tissue engineering applications. It is widely acknowledged that achieving a balance between the required structural and dimension properties, biodegradability, and biocompatibility is essential for the performance of tissue scaffolds (Kirillova et al., 2021; Li et al., 2019a). Several techniques have been developed and conventional fabrication techniques modified to suit the increasing needs of modern tissue scaffolds. This section presents the different methods of synthesizing BPSs. A comparison of various approaches is made to present the distinct benefits and drawbacks of various methods.

7.2.1 Molding

Compression and injection molding are traditional polymer fabrication techniques (Okonkwo et al., 2020). Compression molding utilizes both heat and pressure to melt a thermoplastic polymer or cure a partly polymerized thermosetting resin in a mold (Okonkwo et al., 2020; Viera Rey and St-Pierre, 2019). It has a short cycle time and low material loss. In injection molding, pressurized polymer melts are fed into a mold to solidify and form the desired shape. An advanced form of injection molding is reaction injection molding, which utilizes low viscous resins and allows for in situ polymerization to occur in the mold. Due to their simplicity, these two melt processing techniques have been used in fabricating scaffolds from an array of bioresorbable polymer-based scaffolds and composites (Kirillova et al., 2021; Quiles-Carrillo et al., 2018; Viera Rey and St-Pierre, 2019).

Zhang et al. (2016) reported the fabrication of a high-modulus composite scaffold made of PLLA, PLGA, and HA for healing cranial bone defects via a high-pressure compression molding and salt leaching technique (Zhang et al., 2016). Fabricated scaffolds were observed to possess compressive strength and modulus comparable to cranial bones and excellent osteogenic properties. Salmoria et al. (2017) reported the fabrication of PCL and PCL/ibuprofen (IBP) with excellent cytocompatibility and drug-release properties via injection molding (Salmoria et al., 2017). The fabrication of PLLA-based noncytotoxic interference screws via injection molding has also been reported (Brown and Farrar, 2013).

Compression and injection molding allow for the production of complex shapes with high mechanical properties from all kinds of bioresorbable polymers. Both processes are easy to automate and scale up. Nonetheless, inhomogeneity and unsteady clamping pressure during the fabrication of scaffolds from highly viscous polymer melts, high tooling costs, entrapment of air bubbles, polymer degradation at high temperature and pressure, and

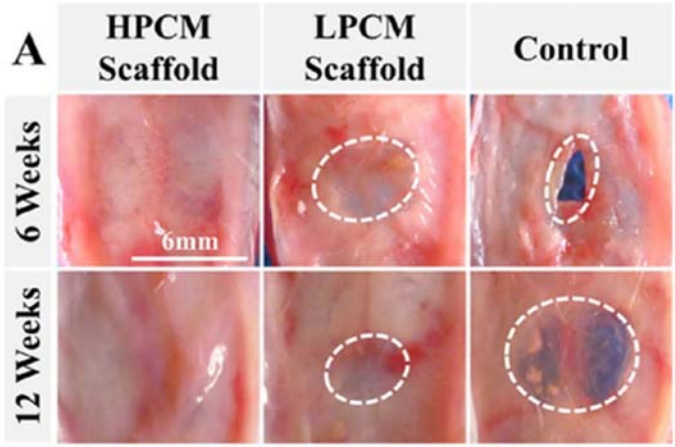

Figure 7.1 Pictures of revived skull defects at 6 and 12 weeks after implantation of high-pressure compression-molded (HPCM) polymeric biodegradable scaffolds. *(© 2016, American Chemical Society (Zhang et al., 2016).)*

residence time are some major drawbacks (Pertici, 2017; Viera Rey and St-Pierre, 2019). Processing parameters (pressure, temperature, and time) have been shown to significantly influence the properties and performance of BPSs fabricated via these molding techniques. PLLA/PLGA/HA scaffolds fabricated at high pressure were found to exhibit more impressive mechanical, cytocompatibility, and tissue regenerative properties as compared to those fabricated under lower pressure (Zhang et al., 2016) (Fig. 7.1). Injection molding has also been shown to impact the crystallinity of PLLA screws (Sadeghi-Avalshahr et al., 2016). As such, variants of the original techniques including the use of cyclic pressure, which Betanzos et al. observed can lead to a 30% improvement in strength as compared to conventional compression molded scaffolds and microwave-assisted compression molding (Barrera Betanzos et al., 2016; Singh et al., 2019), have been suggested. Furthermore, the molding process might be unable to produce scaffolds with a similar degree of porosity and interconnectivity as other methods, such as electrospinning. This is an important consideration for tissue engineering applications, as porosity and interconnectivity are critical for cell infiltration and proliferation. Therefore, molding techniques are normally combined with other techniques including particle leaching and supercritical gas foaming (Ozkoc et al., 2009; Zhang et al., 2016).

7.2.2 Melt extrusion

In melt extrusion, profiles (sheet, porous fiber, film, etc.) are made by forcing polymer melt through a die under regulated conditions. Extrusion machines adopt either the ram or screw extrusion approach, of which twin-screw extrusion is the most common and widely used mixing and compounding method. Extrusion is a widely used technique for fabricating bioresorbable polymer composites. It is used in making precursor (feed material) for other techniques (Casarin et al., 2011). The heating and agitation lead to the production of a homogeneous mix and eliminate the need for drying. In addition, no solvent is required, hence there is lower toxicity and no need for later washing/cleaning (Kenny et al., 2015).

Although solvent-free nanofibers can be produced via extrusion, it is specific to thermoplastic polymers. In addition, bioresorbable polymers are heat- and moisture-sensitive and hence need not be kept molten for a long time. This and the inability to produce scaffolds with consistent pores are some of the drawbacks of the melt extrusion technique. As such, it is often merged with other techniques such as particle leaching. Mendibil et al. (2019) reported the fabrication of PLCL bioresorbable polymer scaffold using sodium chloride as porogen particles. Long (300 mm) and thick (400 μm) microporous PLCL tubes with similar mechanical properties to nerves and veins were achieved. The authors noted that the particle size and proportion of NaCl porogen affected the scaffold's porosity and mechanical properties.

7.2.3 Solvent casting and particle leaching

Another straightforward method for creating porous scaffolds is solvent casting. Solvent casting involves dissolving a polymer in an appropriate organic solvent to create a slurry, casting the slurry on a membrane, and then evaporating the solvent (Kirillova et al., 2021; Viera Rey and St-Pierre, 2019). Solvent casting can be used to produce drug-loaded scaffolds or blend polymers. Particle leaching can also be used to introduce porosity in nonporous prefabricated scaffolds. Herein, particulates (porogens) are added to a polymer melt or slurry prior to casting and, afterward, washed out to yield well-defined pores. Together with particle leaching, porous scaffolds with interconnected pores can be made using this technique (Kirillova et al., 2021). Particle leaching is often called salt leaching because NaCl, owing to its high thermal stability, resistance to organic solvents, and solubility in water, is the most widely used porogen (Modolo et al., 2022; Ozkoc et al., 2009). Nonetheless, the use of organic particles including sucrose, gelatin,

and stearic acid has been reported (Kirillova et al., 2021; Viera Rey and St-Pierre, 2019). This technique presents a simple approach to engineer interconnected pores; however, the achieved pore size is influenced by the porogen size. The settling of the porogen during solvent evaporation can cause nonuniformity in the porosity of the scaffold. More importantly, this approach is not suitable for producing thick scaffolds because of the limitation on the thickness of the produced scaffolds (<3 mm). Due to the potential cytotoxicity of residual solvents and porogen, post-processing is frequently required (Viera Rey and St-Pierre, 2019).

7.2.4 Gas foaming

Porous structures with distinct and interconnected pores of precise sizes are essential for tissue vascularization. Gas foaming is another method often used to produce scaffolds. Herein, gas bubbles are blown into solid polymeric samples to form pores (de Matos et al., 2015). Various gases including supercritical CO_2 and N_2 have been used (Kosowska et al., 2022). Compared to solvent casting and particle leaching, no toxic chemical reagents that can cause cytotoxicity are used (Francis et al., 2023). It can also be performed at room temperature, although heating may be required if combined with molding techniques or for better pore formation (Kosowska et al., 2022).

Several research groups have combined gas foaming with other techniques to fabricate tailored scaffolds. Salerno et al. (2017) combined supercritical CO_2 gas foaming and freeze drying to synthesize scaffolds loaded with drugs (Salerno et al., 2017). In another study, a combination of supercritical CO_2 gas foaming and particulate leaching was used to fabricate a bimodal PCL scaffold with both macro- and microporosity (Salerno et al., 2012). It should be noted that foaming parameters and choice of porogen can influence the architecture, crystallinity, and mechanical properties of the fabricated scaffold. Kosowska et al. (2022) investigated the influence of foaming parameters and porogen type on the properties of PCL. These authors observed that pore morphology, including diameter and density, was dependent on the porogen, whereas mechanical strength and polymer crystallinity depend on foaming parameters such as the saturation time, temperature, and pressure. Porogens increased the nucleation sites, and improved both mechanical strength and degree of crystallization.

One major drawback of gas foaming is the poor control of the pores' characteristics. Similarly, reproducibility of pore architecture is poor. While

the use of microfluidic devices might mitigate this challenge, it will also increase the processing cost.

7.2.5 Electrospinning

Electrospinning is another common method of fabricating biodegradable scaffolds for tissue engineering applications. An electric field is utilized in electrospinning to deposit a polymer solution or melt through a small nozzle, creating a stream of polymer fibers. These fibers are then deposited on a grounded collector to form a nonwoven or woven scaffold (Lannutti et al., 2007). One of the main benefits of the electrospinning technique is the capacity to create highly porous scaffolds with precise control over the pore size and interconnectivity. Scaffolds of various shapes can be formed by altering the collector, which is a critical feature for TE applications, as shapes of scaffolds allow for better cell infiltration and proliferation (Ameer et al., 2019). When combined with solvent casting and particulate leaching, scaffolds with specific mechanical properties can be created.

Electrospinning has been used to fabricate scaffolds from an array of biodegradable polymers, including polyglycolic acid (PGA), polylactic acid (PLA), poly(ethylene oxide) (PEO), polycaprolactone (PCL), as well as composites and blends (Kirillova et al., 2021; Zhao et al., 2019). An electrospun composite scaffold made from a blend of acrylated L-lactide-co-trimethylene carbonate (aPLA-co-TMC) and polycaprolactone (PCL) was found to possess mechanical properties akin to human blood vessels. The scaffold promoted the development and adherence of human mesenchymal stem cells and so has potential in blood vessel repair (Stefani and Cooper-White, 2016). Electrospun poly-4-hydroxybutyrate (P4HB) nanofiber membranes have been reported to exhibit good mechanical properties, degradation behavior, and cytocompatibility with neural cells, and thus is a potential biodegradable substitute for dural tissue in neurosurgery (Ma et al., 2021). Another study reported the fabrication of a novel hydroxy-functionalized polyester with poly[(hydroxymethyl glycolide)-co-(e-caprolactone)] (pHMGCL) scaffold via electrospinning. In vitro tests showed that they degrade faster than a similar scaffold made from PCL. In addition, chondrocytes adhered to the fibers and the presence of important cartilage-related molecules like GAGs and collagen II was noticed. The excellent degradation, cell adhesion, and differentiation properties of electrospun pHMGCL scaffolds attests to their prospective role in tissue engineering cartilage (Seyednejad et al., 2011). A study by Beck et al. (2021) found that electrospun PU-PCL scaffold loaded with sacrificial PEO

particles showed potential as a scaffold for the correction of congenital heart defects (CHDs) (Beck et al., 2021). PEO particles improved pore size, and decreased stiffness and the inflammatory response of the scaffold, which led to better cell infiltration when compared to the PU—PCL blend without PEO particles.

Electrospun scaffolds have also been reported to possess wound-healing properties. Electrospun PCL/Gel scaffold, when used as a sublayer in a bilayer dressing in an animal wound model, was observed to accelerate wound closure and collagen deposition. This can be ascribed to the excellent biodegradability, biocompatibility, and significant antibacterial activity of the scaffolds (Eskandarinia et al., 2020). A similar observation was noted in electrospun PCL—collagen scaffold. The scaffold mimicked the natural architecture of skin and exhibited similar mechanical and physical attributes. When cocultured with keratinocytes and fibroblasts to promote growth and ECM deposition, the scaffolds promoted regeneration of all three skin layers without scar formation (Ghosh et al., 2022).

Several process parameters, including the nature of the polymer, voltage, solvent, needle dimension, needle-to-collector distance, flowrate, humidity, presence or absence of a rotating collector drum, etc., determine the diameter and alignment of electrospun fibers. Both fiber diameter and alignment affect the degree of cell attachment and proliferation.

7.2.6 3D printing

3D printing is a versatile method of fabricating bioresorbable polymeric TE scaffolds (Sousa et al., 2022). It enables the development of intricate and very permeable scaffolds with precise control over both size and shape (Choudhary et al., 2022). Herein, the scaffold is built layer by layer using a resorbable polymer material (Zopf et al., 2015). The most common polymers for 3D-printed BPSs for bone and cartilage applications are PLA, PGA, and PCL, and a variety of blends (Yeo et al., 2021; Zhang et al., 2021; Shuai et al., 2021; Chen et al., 2020). For instance, interference screws with excellent degradation and bone tissue production properties for bone repairs were successfully fabricated from PDLLA and PDLLA-β-TCP blend via 3D-printing (Shuai et al., 2021). Similarly, 3D printing was able to fabricate a PGA/hydroxyapatite scaffold that promoted bone regeneration and improved bone mineral density (Yeo et al., 2021). An in vivo study of the degradability of 3D-printed interference screws made PDLLA and PDLLA and beta-tricalcium phosphate (beta-TCP) was also observed

to exhibit good degradability, and enhanced the production of bone tissues in sheep (ewes) while showing no adverse histological reactions (Scorsato et al., 2022).

3D-printed scaffolds are easily tailored to meet specific needs. To improve their biocompatibility, Chen et al. (2020) successfully modified the biocompatibility of the tarsal plate scaffolds created using 3D printing by coating them with a matrix of adipose-derived mesenchymal stromal cells. The scaffolds exhibited high biocompatibility with sebocytes, decreased inflammatory and apoptotic gene expression, as well as promoted neutral lipid secretion, thus showcasing the potential of this scaffold as a suitable replacement for the tarsal plate (Chen et al., 2020). Yang et al. (2016) showed that the antibacterial and osteogenic activity of a 3D-printed poly(lactic-co-glycolic acid) (PLGA)—hydroxyapatite (HA) composite can be enhanced by grafting stem cells on the fabricated porous scaffold. The scaffold exhibited improved biocompatibility suitable for orthopedic applications with the presence of stem cells significantly increasing the scaffold's antibacterial property and osteogenic activity (Yang et al., 2016) (Fig. 7.2).

3D printing of resorbable scaffolds offers several advantages over traditional fabrication methods, including the ability to create complex, highly porous structures with explicit control of the shape and size of the scaffold. It also allows for a high degree of customization, making it possible to create

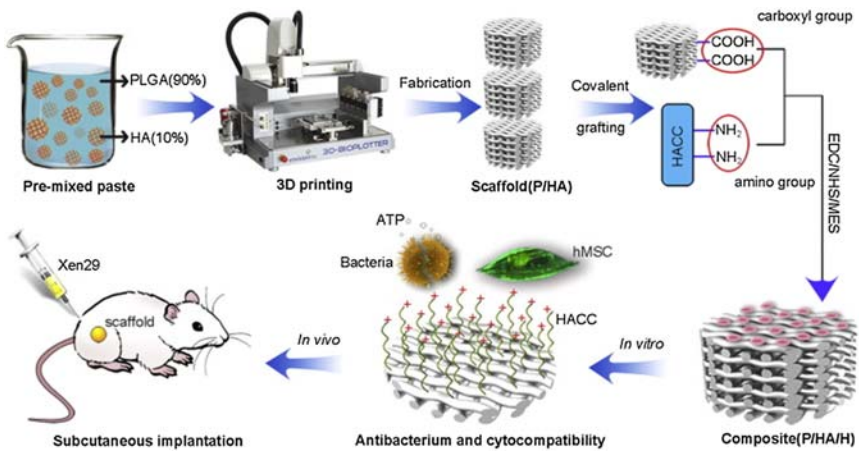

Figure 7.2 Synthesis and antibacterial mechanism of 3D-printed PHA/H composite scaffolds. *(© 2016 Acta Materialia Inc. Published by Elsevier (Yang et al., 2016).)*

scaffolds that can be adapted to the unique requirements of the patient and the tissue engineering application.

7.2.7 Hybrid techniques

The drawbacks and strengths of several techniques in synthesizing tailored scaffolds led to interest in the hybridization of conventional techniques and the development of newer ones. A soft lithographic technique such as microcontact printing, which permits the application of a molecular ink transferred from an elastomeric stamp to a surface, has been shown to be a simple and effective approach to tailor scaffolds. Altomare et al. (2010) reported the microprinting of fibronectin stripes of varied width on L-lactide/trimethylene carbonate copolymer (PLLA-TMC) films. Microscopic examination revealed a stable pattern of fibronectin on the PLLA-TMC surface. The C2C12 cells were well aligned along the pattern 24 h after seeding, and cell alignment was observed after 7 days, which shows that fibronectin patterning can induce cell alignment and improve myotube formation (Altomare et al., 2010).

Some nonconventional techniques and a blend of fabrication methods have been utilized to create bioresorbable polymer scaffolds with specific properties and geometries capable of being used in a variety of tissue engineering applications. For example, vacuum heating-press sintering was used to fabricate a b-TCP-based composite as scaffold for bone defect repair. The presence of magnesium in the scaffold improved the degradation and mechanical properties as well as the osteogenic activity of the composites. In addition, in vivo studies have revealed that these composites are promising materials for clinical bone repair (Yao et al., 2023). Shishatskaya et al. (2022) employed a combination of solvent casting and electrostatic spinning techniques in fabricating films and nanomembranes of poly-3-hydroxybutyrate [P(3HB)] and its copolymers for skin regeneration. The films and nanomembranes exhibited biocompatibility and aided the adhesion, proliferation, and preservation of cells for nearly 1 week. Furthermore, the type 1 collagen-coated polymeric nanomembranes were effective in the regeneration of skin defects, notably the electrospun non-oriented nanomembranes of low-crystalline P(3HB-co-4HB) copolymers (Shishatskaya et al., 2022) (Fig. 7.3).

The thermally induced phase separation (TIPS) technique is another method for preparing scaffolds with linked porous structures. It has been successfully used to produce a BPS from PLGA and a combination of PLGA and polyethylene glycol (PEG) (Yousefi et al., 2019).

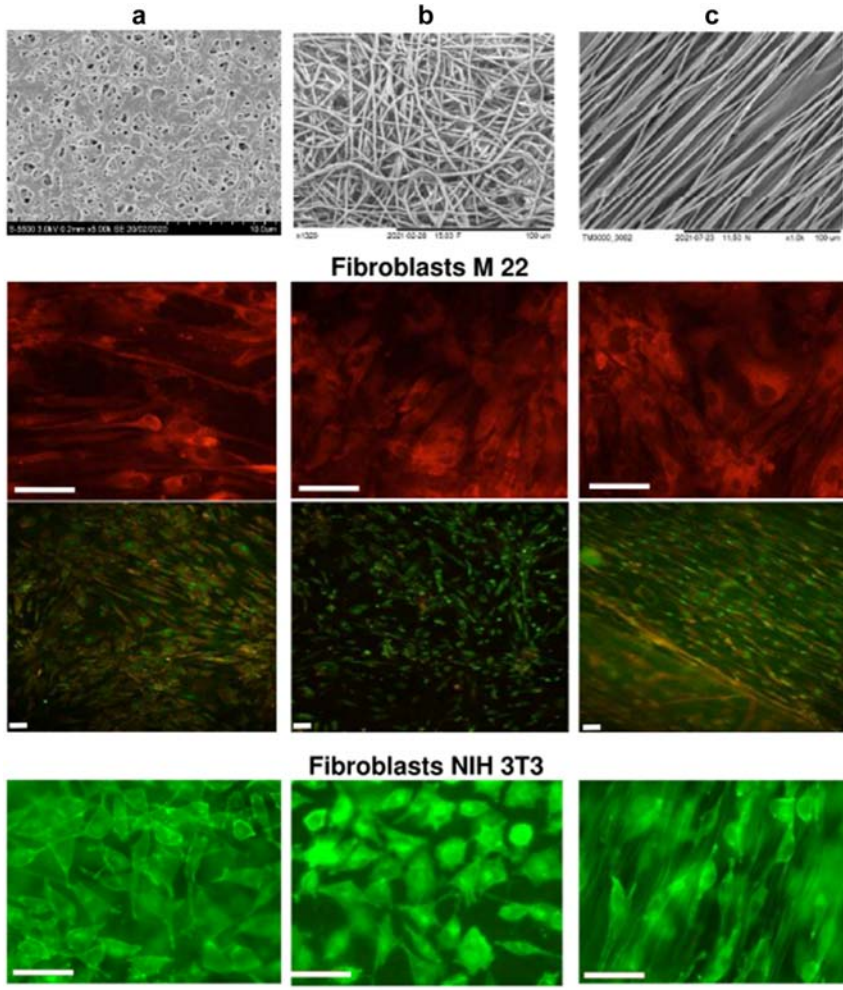

Figure 7.3 A combination of polymer casting and electrospinning were used to fabricate nanomembranes. This figure shows fibroblasts cultivated on P(3HB-co-4HB) polymer carriers: (a) Solvent-cast film; (b) random nanomembranes; (c) aligned nanomembranes. *(© 2022 by the authors (Shishatskaya et al., 2022).)*

7.3 Applications of bioresorbable tissue scaffold

Bioresorbable polymers have been utilized in different areas of tissue engineering ranging from wound dressing, skin regeneration, bone repair, to cartilage and other blood vessel regeneration (Hajebi et al., 2020). This section highlights some of the main areas of the applications of BPSs in

regenerative medicine with a focus on areas where the resorbability and mechanical properties of the polymer scaffolds play a critical role.

7.3.1 Vascular grafts and stents

Following their high tunability and resorbability, BPSs gained a lot of attention as next-generation materials for stents and grafts in the treatment of cardiovascular diseases. Against the drawbacks of traditional stents such as the risk of vascular inflammation, neoatherosclerosis, incomplete endothelialization, and poor suitability to noninvasive imagining, BPSs can provide transient support, allow for vasomotor function, maintenance of vessel geometry, and mitigate the occurrences of stent thrombosis in the hemodynamic environment (Jinnouchi et al., 2019; Sharma et al., 2018; Wiebe et al., 2014). Challenges of traditional grafts such as thromboembolic complications and calcification, and high failure rate can also be mitigated using these polymeric scaffolds. In addition, the growth of new tissue is also promoted, which mitigates the need for maintaining permanent grafts in the body.

The performance of BPSs as vascular grafts and stents has been extensively reported in in vivo and in vitro studies (Fukunishi et al., 2017; Nelson et al., 2008; Wiebe et al., 2014; Zamiri et al., 2010). Fukunishi et al. (2017) evaluated the performance of 3D-printed electrospun PGA/PLCL scaffolds as a bypass graft for the inferior vena cava (IVC) using a sheep model. The authors observed that all the animals survived the implantation, and no extracellular matrix deposition or endothelialization occurred. The fabricated scaffolds were almost resorbed at the end of the trial (6 months). In addition, the newly developed tissues exhibited similar mechanical properties as the native one. Zamiri et al. (2010) evaluated the biocompatibility of several BPSs for vascular stents in vitro and in vivo in pigs. In vitro studies showed that the fast-degrading PLGA materials showed significant mass loss in the first weeks, while PLA braids exhibited only minimal degradation. An in vivo study showed that tested polymers such as 10:90 L-PLGA and PDO with an absorption time of less than a year illustrated excellent vascular biocompatibility and hence are suitable for intravascular stents. Polak-Krasna et al. (2021) evaluated the behavior of medical-grade PLLA for medical stents under accelerated degradation conditions for absorbable stent application over a 112-day test period. The samples were found to consistently have lower molecular weights and only slightly altered mechanical characteristics in the first 30 days. A further decrease in molecular

weight and substantial reduction in tensile strain occurred after 70 days, while mechanical properties such as elastic modulus, yield, and tensile strength were unaffected. After 112 days, the samples became too brittle, thus indicating substantial loss of their load-bearing capacity. Across the test duration, the degree of crystallinity and melt temperature decreased and there were minor changes in glass transition temperature.

While these studies buttress the already established potentials of BPSs, some clinical trials such as Absorb BVS, Igaki-Tamai, ART-BRS, and DeSolve show that some complications attributable to scaffold design exist. To meet the radical strength requirement, BPSs are often designed to have a large strut thickness. However, delayed healing and risk of malapposition have been found to increase with strut thickness. It is pertinent to state that scaffold design and material selection will be key, as shown in on-going clinical trials (Fioretta et al., 2021; Jinnouchi et al., 2019). Herein, the incorporation of nanofillers to tailor the properties of already known polymers such as PLA, polymer blending, and virtual testing of cell shapes will be beneficial (Mahmud et al., 2021; Okereke et al., 2021).

7.3.2 Bone and cartilage tissue fixation

BPSs in the form of plates, screws, bars, and pins can be used as implants for bone and cartilage tissue repair, where they can provide mechanical support and accelerate the healing process. Time-dictated deterioration of mechanical properties due to degradation of BPSs averts stresses which are common during bone healing using conventional implants (Brown and Farrar, 2013). Different research groups have investigated the performance of BPSs in orthopedics. It is widely acknowledged that scaffolds made from bioresorbable polymers such as PLA and its derivatives possess properties that enhance bone tissue repair, and challenges such as low mechanical properties, poor osteogenic differentiation capacity, incompatible degradation rate, and acidic degradation product-induced inflammatory responses can occur. Using rabbits with distal ulna defect, Weng et al. showed that while PLLA/PCL and PLLA scaffolds can be used for bone regeneration, the degradation rate was low and the polymers lacked osteoinducibility (Weng et al., 2014). Surface modification with nanoparticles such as nano-bioactive glass, as reported by Mahdavi et al. (2017), can be used to improve the osteogenic differentiation capacity. Other $Ca_3(PO4)_2$-based compounds such as hydroxyapatite, β-TCP, and calcium sulfate either blended, coated, or grafted have also been reported to improve the

osteogenic properties of polymer scaffolds (Hussain et al., 2022). Recently, the addition of metals such as magnesium and metal oxides to the polymers has been used to improve both biocompatibility and mechanical properties. Chan et al. (2019) observed that the presence of oxides of hafnium, titanium, zirconium, and silicon in electrospun PLLA scaffolds improved both the mechanical and osteogenic properties of PLLA. Blending with other polymers has been utilized to tailor the degradation rate, mechanical properties, and nature of the formed degradation products. With more alkaline polymers such as PPC and PTMC, less acidic degradation products with a reduced risk of inflammatory reactions are achieved. Hua et al. (2009) observed that PLLA blended with PTMC reduced the acidity of the formed degradation product. Further, the addition of PGA-TMC into PLLA-TMC enabled the fabrication of scaffolds with improved degradability and mechanical properties suitable for bone tissue engineering applications. These scaffolds can be fabricated through a low-temperature 3D-printing method (Hu et al., 2023).

Scaffolds such as polycaprolactone have been reported to find application in cartilage regeneration. Gruber et al. (2022) showcased the potential of PCL scaffolds embedded with PLA microspheres bearing decellularized cartilage matrix for osteochondral regeneration. The scaffolds were observed to provide mechanical support and to aid seeded mesenchymal stem cells in forming mesenchymal condensates, which is a biochemical marker of cartilage development (Gruber et al., 2022). A chitosan/poly ε-caprolactone polymer blend was reported to facilitate neo-cartilage formation (Neves et al., 2011). PCL increased the mechanical properties and reduced the swelling ratio of the scaffold. Zhao et al. found a PLGA scaffold bearing icariin to be effective in inhibiting the progression of osteoarthritis. A histological evaluation revealed that the scaffold repressed the resorption of subchondral bone trabeculae and preserved the shape of the articular cartilage (Zhao et al., 2019).

7.4 Future trends

The field of scaffold fabrication is constantly evolving, with new advancements in materials science, biotechnology, and manufacturing technology shaping the future of this subject. One of the key trends in scaffold fabrication is biomimicry, where researchers aim to develop scaffolds that mimic the structure, composition, and mechanical properties of the native extracellular matrix (ECM) of the tissue being regenerated. By replicating

the natural environment of the tissue, these scaffolds can promote cell migration, proliferation, and differentiation, leading to more efficient and effective tissue regeneration.

Another trend in scaffold fabrication is the development of tissue-specific scaffolds, designed to meet the specific needs of different types of tissue such as bone, cartilage, or nerve tissue. Tailoring the environment to the specific needs of cells improves the efficiency and effectiveness of tissue regeneration. This, in combination with bioprinting, where functional tissue constructs bear living cells together with a hydrogel support material are printed using 3D printing technology, will further enhance the field of TE. Bioprinting enables precise control over the mechanical and surface properties, as well as the degradation rates of the scaffold, thus making it ideal for specific TE applications.

Smart scaffolds are also becoming increasingly popular. These are designed to react to changes in temperature, pH, or specific molecules in their environment. The poor adaptability of traditional scaffolds is one of their main limitations, hence engineering scaffolds with the ability to change will ultimately improve their efficiency and effectiveness in regenerating tissues. Similar to smart scaffolds, the use of nanotechnology to create scaffolds with precise control over the size, shape, and composition is a current trend that will continue to dominate. With nanotechnology, customized scaffolds can be easily made.

Composite scaffolds made through the combination of different materials such as polymers, ceramics, and natural materials is another important area of scaffold fabrication with huge prospects. Composite materials have been known for their exceptional properties (Aigbodion et al., 2019), thus, scaffolds with improved properties such as degradation rate, mechanical strength, and biocompatibility, that can further enhance tissue regeneration, can be made using composites. The future of scaffold fabrication will be marked by the increasing use of advanced materials and technologies to create scaffolds that are highly specific and customized to the needs of different types of tissue, leading to more efficient and effective tissue regeneration (Samadian et al., 2020).

7.5 Conclusion

Numerous methods, including molding, electrospinning, and 3D printing, are available for creating bioresorbable scaffolds; however, the properties of the scaffolds fabricated using these techniques are often limited. Therefore,

creating scaffolds with specific properties and geometries by combining different fabrication techniques will likely dominate the future of bioresorbable scaffolds for tissue engineering. By combining different methods, scaffolds with enhanced properties can be produced while inherent limitations of individual fabrication techniques are minimized. For example, electrospinning can be used to create scaffolds with high porosity, while solvent casting can be used to create scaffolds with more complex geometries and controlled pore sizes. By combining the two methods, it may be possible to produce scaffolds that have both high porosity and complex geometries (Li et al., 2019b). Similarly, the combination of microcontact printing with electrospinning or 3D printing could be used to create scaffolds that have specific patterns of growth factors or other molecules on the surface to promote cell adhesion and tissue growth (Si et al., 2022).

Besides the combination of fabrication techniques, the use of advanced materials such as biodegradable polymers with tunable mechanical and degradation properties is also likely to become more widespread in the future. The development of biodegradable polymers that can mimic the properties of natural tissue is an important goal in the field of tissue engineering, and the combination of different fabrication techniques with these advanced materials is likely to lead to the production of more effective scaffolds for an array of tissue engineering applications (Ciardulli et al., 2021).

The future of bioresorbable scaffolds will require a multidisciplinary approach, involving collaboration between materials scientists, engineers, and biologists, to fabricate scaffolds for effective regeneration of tissues.

8.1 Introduction

Hydrogels are three-dimensional network structures with cross-linking, which usually are constructed from synthetic or natural hydrophilic polymers. The hydrogels can be cross-linked chemically and physically through covalent bonds, hydrogen bonds, crystallized domains, or hydrophobic interactions (Li, 2003; Li et al., 2005). Normally, hydrogel networks are formed via chemical reactions of monomers, creating bonds between polymer chains. As a result, the absorption of water could be up to hundreds or thousands of times without dissolution in water (Hu et al., 2012). The recent development of hydrogels aims to achieve unique characteristics such as controllable swelling behavior, capability to retain water, improved degradation and mechanical properties, mild processing conditions, and outstanding biocompatibility, thereby overcoming deficiencies found in traditional hydrogels. Thereby, enhancing their broad applicability and expanding the potential tasks of hydrogels in health and biomedical applications such as bone and cartilage regeneration, tissue engineering, biosensor, wound injury, and target delivery of drugs (Hu et al., 2012; Wang et al., 2019; Kesharwani et al., 2021; Ahmed, 2015). Typically, hydrogels can be sorted by the source of materials, including natural polymers, synthetic polymers, and semisynthetic or a combination of natural and synthetic polymers. Various naturally derived polymers have been used to form hydrogel networks, such as polysaccharides, collagens, gelatin,

fibrin, chitosan, alginate, and cellulose, which offers drug delivery, biocompatibility, and biodegradability (Kesharwani et al., 2021; Nele et al., 2020; Peng et al., 2011; Chatterjee et al., 2018; Mondal et al., 2020). However, these naturally derived polymers have some drawbacks, such as immunogenicity, limited mechanical performance, and uncertainties due to batch-to-batch variations. As a result, synthetic polymers based on poly(ethylene glycol) (PEG), polyacrylic, poly(vinyl alcohol) (PVA), and poly(acrylamide) (PAM) have been seen as potential materials for hydrogel forming due to their high physical strengths and desirable flexibility, which are vital features for expanding hydrogel utilization (Singhal and Gupta, 2015). Synthetic polymers offer ease of functionalization and design, as well as increased mechanical properties. However, they lack biocompatibility and biodegradability. As a result, to merge the strengths of synthetic and natural-derived polymers, a raft of semisynthetic materials, such as gelatin methacrylate (GelMA) and hyaluronic acid methacrylate (HAMA), have been established.

Bioresorbable hydrogels have gained extensive consideration in targetable drug release and therapeutic applications as excellent carriers. The unique characteristics of hydrogels, such as the controllable swelling properties, biodegradability, and biocompatibility, have boosted their utilization, particularly in controlled drug-delivery applications. Also, their porous structures facilitate their ability for drug loading and ultimate release through the hydrogel networks. Typically, the loaded drug is delivered through hydrogels by being slowly eluted, maintaining a high drug concentration in the target for a considerable duration. Hydrogel-based delivery systems can be applied for many areas, such as oral, topical, ocular, vaginal, and rectal. The considerable functions of the hydrogels are prolonging drug release and reproducing drug-releasing profiles.

8.2 Cross-linking of hydrogels

Various techniques have been applied for hydrogel formation with the main principle of cross-linking polymer chains. Traditionally, hydrogels are broadly classified into physically and chemically cross-linked hydrogels (Zafar et al., 2021). Conventional and controlled radical polymerization techniques are used to prepare hydrogels with different compositions, sizes, and morphologies. Applying functional initiators and macroinitiators enables the contribution of functional groups, both inside and on the surface of the hydrogels, thus facilitating multivalent bio-conjugation. In addition,

hydrogels may consist of a double network in which both physical and chemical cross-linking occur, as shown in Fig. 8.1.

8.2.1 Physical cross-linking

Physically cross-linked hydrogels have gained much attention due to their ease of production, prevention of toxic cross-linking agents, and involvement of biopolymers. The physical networks can be concurrently connected by molecular entanglements, hydrogen bonds, ionic forces, and van der Waals interactions. Physical cross-linkers, for example, chitosan, carrageenan, and hyaluronan, can be used to entrap integral materials such as proteins and drugs, making physical hydrogels receive significant attention currently, mainly in the functional food and drug-delivery sectors (Kesharwani et al., 2021). Several methods, such as charge interactions, crystallization, and stereocomplex formation, are typically used to fabricate physically cross-linked hydrogels (Zafar et al., 2021).

8.2.1.1 Stereocomplexation

Stereocomplex formation is a well-established phenomenon found in the co-precipitation of poly(L-lactide), so-called PLLA, and poly(D-lactide), so-called PLDA, in solution, through cooling from their melts, or during their hydrolytic degradation. Hydrogel based on water-soluble PLA-based copolymers has been explored in drug-delivery systems and temporary therapeutic applications, including internal fixation devices and drug-

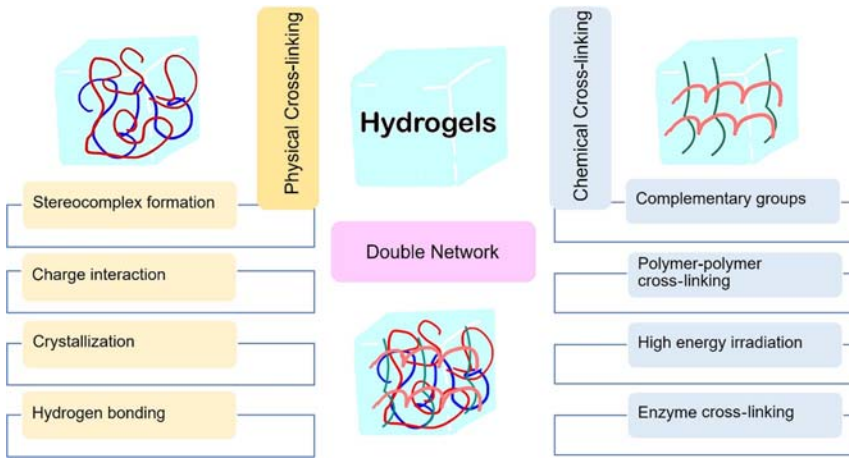

Figure 8.1 Cross-linking strategies in hydrogel forming: physical, chemical, and double networking.

delivery devices (Hu et al., 2012). For example, Zhang et al. suggested the fabrication of bioresorbable hydrogels for drug-delivery systems from water-soluble PLA—PEG—PLA triblock copolymers through stereocomplexation of PLLA and PDLA chains. However, the conventional stereocomplex process, such as solution blending, is relatively slow. Im et al. developed a novel process based on oil-in-water (O/W) emulsion blending, considerably improving the efficiency and speed of the reactions. The PLA hydrogel obtained from O/W emulsion blending exhibited superior mechanical and chemical properties (Im et al., 2020). Fig. 8.2 displays a schematic of O/W emulsion blending for stereocomplexation between PLLA and PDLA induced by O/W emulsion blending. Several considerations, such as copolymer concentration, copolymer composition, type of drug, and the difference between sol and gel characteristics, affect the efficiency of drug delivery. Higher copolymer concentration and molar mass lead to a slower rate of releasing and less bursting effect due to a more compact structure, which disfavors drug diffusion. In addition, the presence of both PLLA/PEG and PDLA/PEG in hydrogels slows the release rates compared to those of single-copolymer solutions.

Interestingly, chitosan-graft-polylactide copolymer (CS-g-PLA) hydrogels can be produced based on the stereocomplexation strategy to obtain a highly efficient drug carrier. By mixing aqueous solutions of CS-g-PLLA and CS-g-PDLA, a hydrogel network can be formed via stereocomplexation of PLLA and PDLA blocks (Hu et al., 2012). The CS-g-PLA hydrogel was reported as a great potential material for drug release, with 82% of TP5

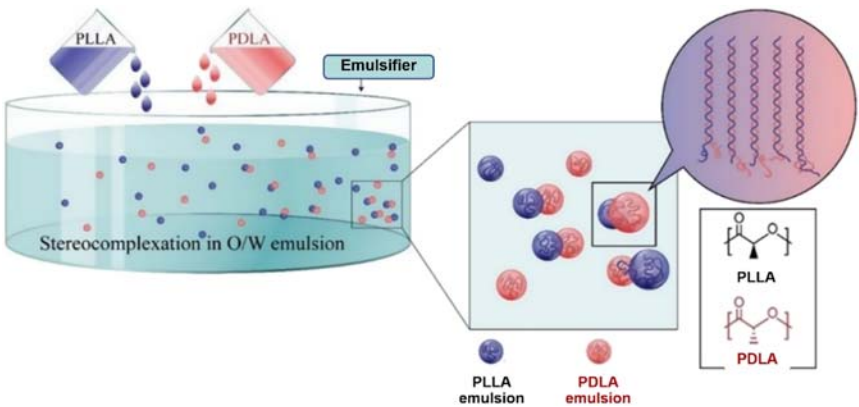

Figure 8.2 Schematic of oil-in-water (O/W) emulsion blending for hydrogel formation from stereocomplexation between PLLA and PDLA blocks. *(Reprinted with permission from Im et al. (2020).)*

(Thymopentin, a model drug) released from the hydrogel within 6 h. Consequently, the inner porous structure of the hydrogel controlled the more rapid release capability. The pores were well interconnected and thus benefited drug diffusion. In general, drug-release mechanisms can be identified as diffusion- or degradation-controlled drug-delivery behaviors. Also, drug diffusion is prevalent, which may be attributed to the reliable water solubility of TP5 and the favorably porous structure of hydrogels. The time scale for TP5 release is shorter than the degradation rate of PLA-based hydrogels, indicating that the developed CS-g-PLA hydrogels are promising candidates for bioactive molecules delivery, particularly hydrophilic drugs such as TP5 and insulin (Hu et al., 2012).

In addition, a simple physical cross-linked hydrogel can be formed by simply warming block-copolymer solutions such as the block-copolymer of poly(ethylene glycol), polylactic acid, and poly(ethylene oxide)−poly(propylene oxide)−poly(ethylene oxide) hydrogels (Wang et al., 2019; Im et al., 2020).

8.2.1.2 Cross-linking by charge interactions

Charge interaction can occur between two or multiple opposite-charged polymers and small molecules, resulting in a temporary hydrogel formulation such as the alginate hydrogel cross-linked by divalent cations, for example, calcium (Ca^{2+}), barium (Ba^{2+}), and magnesium (Mg^{2+}) (Zafar et al., 2021; Hu et al., 2019). Ionic hydrogels, cationic hydrogels, and anionic hydrogels have cross-linking of ionic polymers involved by adding divalent or trivalent counterions. Electrostatic interactions take place between the opposite-charged polymers, which then network with each other, generating polyelectrolyte complexes. The swelling of ionic hydrogel is typically dominated by the pH of the aqueous medium, which further defines the degree of dissociation of the ionic chains (Kesharwani et al., 2021; Singhal and Gupta, 2015; Hu et al., 2019). Examples of hydrogels fabricated based on ionic interaction cross-linking are chitosan−dextran hydrogels and chitosan−glycerol phosphate salt. The particular benefit of ionic interaction is its self-healing ability. Thus, when the physical network of hydrogel is broken at high stress, it can be reformed once the stress is removed. However, the mechanical performance of hydrogel remains limited due to the cross-linking strategy of the ionic interaction (Hu et al., 2019).

8.2.1.3 Cross-linking by crystallization

The crystallization of polymeric chains acts as a physical cross-linking site for hydrogel formation. For example, the hydrogel can be formed from the freeze–thawing process of the aqueous PVA solution. The obtained hydrogel properties can be altered with polymer molecular weight and concentration, freezing time, and temperature, as well as the number of freeze–thaw cycles. For example, a PVA/sodium alginate (SA) hydrogel was formed via freeze–thawing, using an NaCl solution. The obtained hydrogel was found to be improved in strength and conductivity. In addition, a physical double network (PDN) hydrogel can be prepared based on the crystallization-induced physically cross-linked PVA and polyacrylamide (HAPAM) by one-pot in situ polymerization and subsequent freeze–thawing cycling, as shown in Fig. 8.3. The obtained PDN hydrogel exhibited improved mechanical strength, owing to the substantial crystallization of PVA combined with the presence of an H-bond between the PVA and PAM chains (Hu et al., 2019).

8.2.1.4 Cross-linking by hydrogen bonding (H-bonding)

H-bonding is one of the most significant noncovalent interactions that can stabilize a hydrogel formation. Some examples include the hydrogel beads from carboxymethylcellulose (CMC) filled with graphene oxide (GO) nanoparticles prepared by lowering the pH of aqueous polymeric solutions surrounding carboxyl groups. The CMC/GO hydrogel was physically cross-linked by $FeCl_3.6H_2O$. Due to the H-bonding between GO and

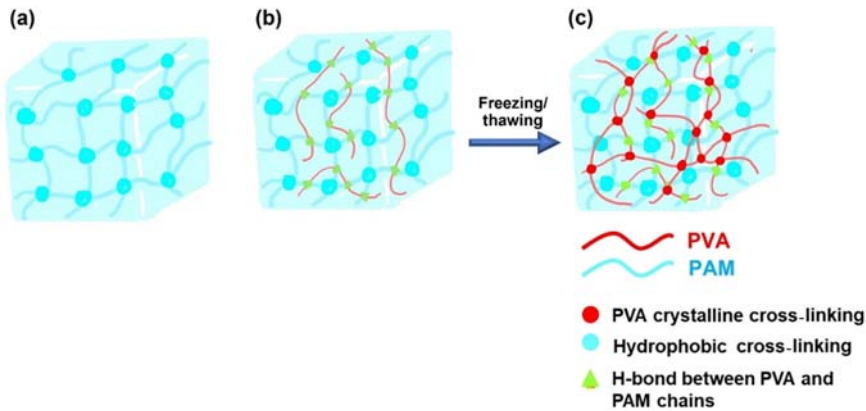

Figure 8.3 The hydrogel network structures developed from the freezing–thawing process: (a) HAPAM hydrogel, (b) semi-IPN HAPAM/PVA hydrogel, (c) PDN hydrogel after freezing–thawing. *(Adapted with permission from Hu et al. (2019).)*

water molecules and carboxyl groups of CMC hydrogels, the swelling ratio of the CMC/GO nanocomposite hydrogel increased compared to the neat CMC hydrogel, indicating the better drug-loading capacity compared to the neat CMC hydrogel (Rasoulzadeh and Namazi, 2017). In addition, cellulose-based hydrogels are typically formed via H-bonding. For example, two biopolymers, pectin and mucin, were incorporated into the hydrogel network in NaOH/urea aqueous solvent system. The obtained cellulose-based hydrogels provided more controlled release at different pH levels, ranging from 1.2 to 10, which allow further advancement of controlled drug-delivery systems (Islam et al., 2022). Moreover, H-bonding could be formed by active groups such as amide, carboxylic acid, and hydroxyl groups, or interact with electron donor groups, such as pyridine and imidazole. So far, a single H-bond is generally not strong enough to maintain the hydrogel structure. A novel self-healing hydrogel with a strong network can be prepared based on the interactions of ureidopyrimidinone (UPy). As shown in Fig. 8.4, a multiblock PEG-UPy copolymer was synthesized through physical cross-linking between UPy-UPy dimers which are surrounded in the PEG matrix. The UPy units could further assemble into dimers via four-fold H-bonding, resulting in network reinforcement with high strength, resiliency, and shape memory behavior (Hu et al., 2019).

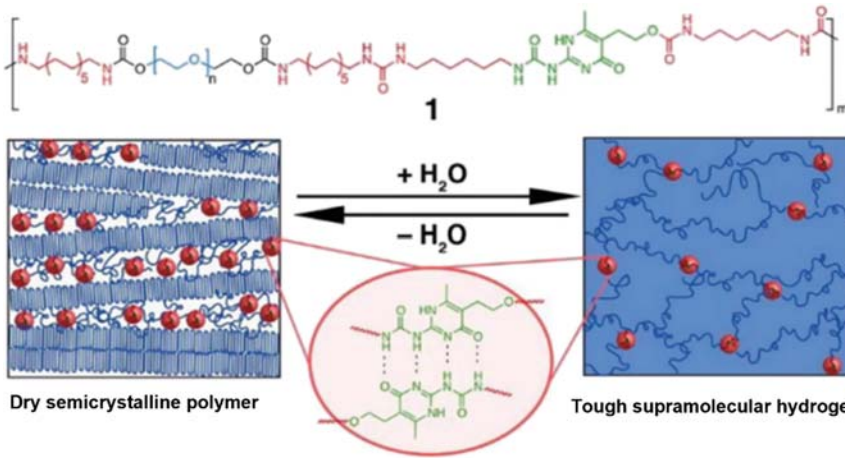

Figure 8.4 Schematic illustration of hydrogel cross-linked via H-bonding between two UPy segments in PEG-UPy hydrogel. *(Adapted with permission from Guo et al. (2014).)*

8.2.2 Chemical cross-linking

Chemical cross-linking is a straightforward and practical approach to obtaining hydrogels. Chemical cross-linking requires grafting polymers or connecting two polymeric chains with cross-linking agents. Covalent bonds are the primary mechanism involved in chemically cross-linked hydrogels which are more substantial and more permanent compared to those of physically cross-linked hydrogels. Numerous approaches have been reported, including the chemical reaction of complementary groups, polymer—polymer cross-linking, high-energy irradiation, and enzyme cross-linking. Compared to physically cross-linked hydrogels, chemically cross-linked hydrogels usually exhibit enhanced stability under physiological conditions, excellent mechanical properties, and tunable degradation behavior.

Some examples of chemically cross-linked hydrogels include the complex hydrogels composed of whey protein isolate (WPI), and chitosan (CS) prepared by cross-linking with a naturally derived cross-linking agent, genipin (GP), via cold gelation. The obtained complex hydrogels show excellent properties for the application of controlled release, in particular, bioactive materials in functional foods and pharmaceutical products (Liu et al., 2018). Another proposed area for hydrogel utilization is artificial skin that affords site-specific medicament delivery. Chemically cross-linked carboxymethylcellulose (CMC) hydrogels were successfully used for targeted drug delivery through the skin (Kesharwani et al., 2021).

8.2.2.1 Chemical reaction of complementary groups

For aqueous-soluble polymers, respective functional groups, including carboxylic (COOH), hydroxyl (OH), and amide (NH_2) groups, are accountable for hydrogel formation. Covalent links between polymeric chains can be created by Schiff-based formation, or reaction of complementary groups, such as a hyaluronic acid hydrogel cross-linked using poly(ethylene glycol) propionaldehyde. The formulated hydrogel is a potential candidate for carrying antibacterial and antiinflammatory properties in wound-dressing applications. In addition, hydrogels can be cross-linked by bis or higher functional cross-linking agents, such as 1,6-hexamethylene diisocyanate, divinyl sulfone, and 1,6-hexane dibromide. The cross-linking reaction is typically undertaken in organic solvents to avoid the reaction of water and the cross-linking agents. The formed hydrogels need to be extracted to remove the trace of unreacted reagents due to the toxicity of such cross-linking reagents, for example, a degradable hydrogel from cross-

linking of polyethylene glycol-dithiol and polyethylene glycol-acrylate. In addition, condensation reactions have also been widely used to prepare polyester/polyamide-based hydrogels. The condensation reaction was conducted through several groups, in particular, $-OH$ or $-NH_2$ with carboxylic acids and their derivatives, for example, hydrogel formulated from alginate and PEG-diamine. The hydrogel formulated via this cross-linking strategy typically exhibits superior mechanical properties compared with the ionically cross-linked counterparts (Zafar et al., 2021; Hu et al., 2019).

8.2.2.2 Polymer–polymer cross-linking

For polymer–polymer cross-linking, the reactive groups of prefunctionalized polymeric chains are utilized for creating the hydrogel network. A well-known example is the chitosan and hyaluronic acid polymer-based in situ hydrogels formed by Schiff-bases reaction at physiological pH, which resulted in a hydrogel that maintained stability for up to 4 weeks. Moreover, Michael addition is a reaction between a nucleophile, the donor with sufficient nucleophilicity, such as amines. The activated electrophilic olefins or alkenes as an acceptor with electron-withdrawing and resonance ability can stabilize the anionic intermediate. This approach offers mild reaction conditions, rapid gel formation, and flexibility in forming multiple bonding. In addition, this cross-linking method eliminates the necessity of low-molecular-weight cross-linkers; however, the limitation is the requirement for multi-step synthesis and purification processes. Fig. 8.5 illustrates the Michael addition of chitosan-based hydrogels cross-linked with poly(ethylene glycol-*b*-caprolactone-*b*-ethylene glycol) (PECL) micelles. Herein, drugs can be trapped inside the PECL micelles, promoting excellent delivery performance (Hu et al., 2019).

8.2.2.3 Cross-linking by photopolymerization

Photopolymerization has been extensively utilized for hydrogel construction in therapeutic applications. The speedy creation of hydrogel networks under mild conditions and the tunable mechanical properties make this method more interesting. Under light exposure, only light-exposed regions are polymerized and promote cross-linking. Typically, the presence of unsaturated groups, for example, the conjugated carbons in methacrylates, are greatly reactive, promoting a free radical chain-growth polymerization under light exposure. Various photoinitiators such as Irgacure 2959, Irgacure 819, Irgacure 1173, LAP, and so on, which can be absorbed by precise

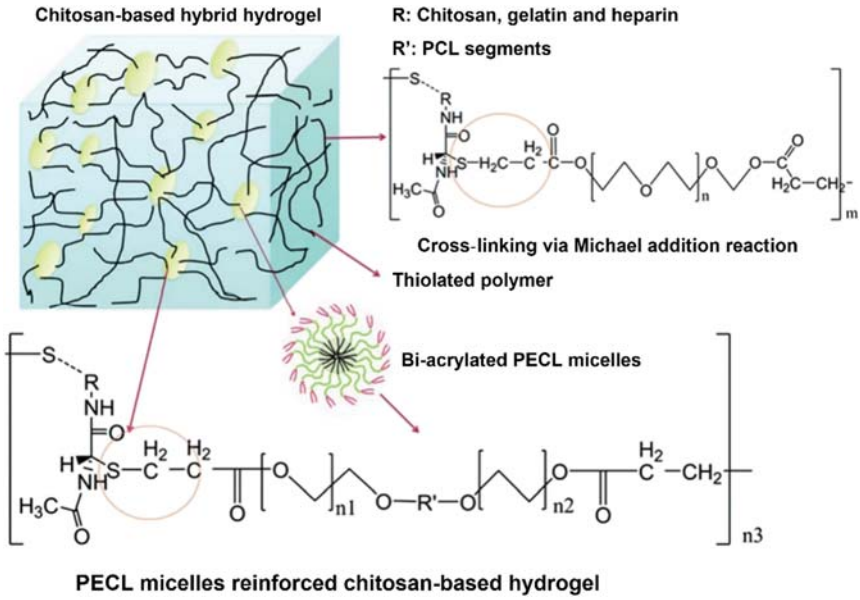

Figure 8.5 Schematic illustration of chitosan-based hydrogel cross-linked with PECL micelles via polymer–polymer cross-linking. *(Adapted with permission from Hu et al. (2019).)*

light at different wavelengths, including UV light at 250–370 nm, visible blue and purple light at 405–550 nm, and red light at 750–810 nm, are typically incorporated to initiate the photopolymerization. In addition, the chemical modification of photoinitiators has recently been more stimulating as it could enhance the photoinitiation performance. For example, using a carboxylated-modified camphorquinone photoinitiator significantly increases the photoactivity and cross-link density with better mechanical properties of the fabricated hydrogels (Hu et al., 2019).

8.2.2.4 High-energy irradiation cross-linking

High-intensity and energy irradiations, including gamma, UV, electron beams, and microwave, can be employed to create permanent hydrogels. Irradiation-mediated chemical cross-linking allows the formation of hydrogels under mild conditions, including pH and temperature, without using toxic cross-linking agents. Thus, the removal of unreacted species from the final product is not required. In the high-energy irradiation cross-linking technique, the produced free radicals attack the hydrophilic part of the polymer chains, generating macroradicals with the consequent creation

of cross-linked networks. Polyacrylic acid (PAA), polyethylene glycol (PEG), and polyvinyl alcohol (PVA) hydrogels are examples of hydrogels formed using this method. In addition, polymethyl vinyl ether aqueous solutions can be irradiated above the phase transition temperature to obtain a thermosensitive hydrogel. The factors influenced the swelling ratio and permeability of the resultant hydrogels are typically the irradiation dose and polymer concentration (Zafar et al., 2021).

8.2.2.5 Enzyme cross-linking

Recently, enzymes have been utilized for formulating hydrogels, for example, PEG-based hydrogels. Numerous enzymes, such as transglutaminases, tyrosinase, peroxidases, plasma amine oxidase, and phosphatases, have been widely used. For example, transglutaminase, along with calcium ions as a cofactor, can promote the formation of amide linkages between carboxamide and amine groups (Zafar et al., 2021). In addition, collagen can be conjugated with tyramine to form an injectable hydrogel in the presence of horseradish peroxidase and hydrogen peroxide (Hu et al., 2019).

8.3 Hydrogel fabrication

Hydrogel fabrication methods are typically based on physical and chemical cross-linking. Different cross-linked networks can be constructed and the properties, particularly the drug-delivery performance, can be designed as required (Kesharwani et al., 2021). The hydrogels for drug-delivery applications fabricated via different routes are described in Table 8.1.

8.3.1 Mold casting

Mold casting is a relatively simple fabrication strategy in which a hydrogel precursor solution is placed into a mold, cross-linked, and demolded. It can be used to produce shape-defined hydrogel structures from various hydrogel systems, for example, enzymatically cross-linked collagen/fibrinogen, photo-cross-linked acrylate PEG, and acrylamide (Nele et al., 2020). In addition, the mold casting method can be assisted by freeze drying, which is called freeze casting. For example, gelatin/chitosan hydrogel can be formed by freeze casting by first dissolving chitosan in acetic acid, then adding a gelatin solution to obtain gelatin/chitosan, which is then stirred until homogeneous blending is obtained. After that, the proper cross-linker, for example, glutaraldehyde (GA), is slowly added. The mixture solution is

Table 8.1 Physically and chemically cross-linked hydrogels for drug-delivery applications.

Cross-linking hydrogels	Cross-linking methods	Materials	References
Physically cross-linked hydrogels	H-bonding	Cyclodextrin, hyaluronic acid, polypseudorotaxane, gelatin	Kesharwani et al. (2021), Feng et al. (2016), and Ye et al. (2017)
	Ionic interaction	Cellulose microfibrils, chitosan	Masruchin et al. (2015) and Ishii-Mizuno et al. (2017)
		Sodium alginate-polyacrylamide	Zhou et al. (2018)
	Stereocomplexation	Polyethylene glycol, polylactic acid, dextran	Wang et al. (2015)
Chemically cross-linked hydrogels	Condensation	Cellulose nanofibers, B-cyclodextrin	Kobe et al. (2016)
	Radiation grafting	Carboxymethyl cellulose, chitosan, styrene sulfonate, N-vinyl caprolactam	Tran et al. (2017)

then poured into plastic molds, allowed to dry for 72−120 h at room temperature, and then dried at −40°C for 24 h to obtain a porous structure. The obtained hydrogels showed a significant reduction in the swelling behavior with increased chitosan cross-linking reagent contents, contributing to the formation of a more rigid network (Peng et al., 2011).

Another interesting example is a novel hydrogel applying drug molecules as cross-linking agents. A small drug solution is introduced into a graphene oxide (GO) dispersion to fabricate the hydrogel under mild conditions (Tao et al., 2012). The GO and drug molecules are dispersed in water and mixed in this process, and the mixture is then shaken for a period of time to form a hydrogel. Then, the drug molecules can be encapsulated in the hydrogel matrix. The freeze-dried and air-dried GO-based hydrogels were seen as prospective candidates for the controlled release of drugs in the strongly acidic environment of the stomach. The GO-based hydrogel with the drug as the cross-linker can be expanded to other hydrophilic drugs containing amino acids and nucleoside peptides.

8.3.2 Prilling or laminar jet break-up

The prilling process is used to prepare monodispersed hydrogel beads based on the dispersion of the solution through pressure-controlled injection in a specific gelation or coagulation medium. It is generally applied for producing polysaccharide-based hydrogels. The polysaccharide solution will transition from the sol phase to the gel phase as a gel particle. The sol phase breaks apart into mono-sized drops through a vibrating nozzle device, as shown in Fig. 8.6 (Auriemma et al., 2020).

This process is generally used for producing polysaccharide-based hydrogel microparticles with designed characteristics, for example, inner structures and diverse configurations, such as mono-layered or multi-layered. The obtained polysaccharide-based hydrogels can be used to control drug release. It should be noted that the hydrogel drying method is a key factor governing the morphology and inner structure characteristics, hence controlling the swelling and releasing properties, in particular for antibiotic and antiinflammatory drugs (Auriemma et al., 2020; Tran et al., 2011).

8.3.3 Nanoparticle-templated nanogel fabrication

Nanometer-sized hydrogels or nanogels have become known as versatile drug-delivery substances which permit large biomolecules to be

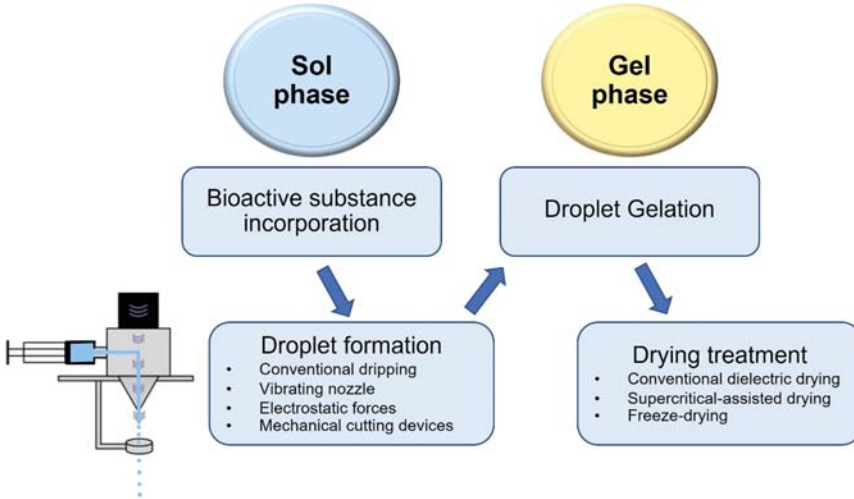

Figure 8.6 Illustration of the typical procedure for producing hydrogels via the prilling process.

encapsulated and released (Nele et al., 2020; Molina et al., 2015; Yan et al., 2017; Torres-Martinez et al., 2019). Conventional methods normally involve inverse emulsion polymerization of cross-linked amphiphilic polymer nanostructures. Instead, nanogel production can be templated by nanoparticles. For instance, liposome-templated nanogels were fabricated by rehydration of liposomes in a polylactide-PEG-polylactide diacrylate copolymer in the presence of a photoinitiator. The suspension was then irradiated with UV light. Similarly, PAM-based nanogels can be formed by encapsulating acrylamide monomers, *N, N′*-methylene-bisacrylamide cross-linker, and photo-initiator in the presence of phosphatidylcholine liposome. The photo-cross-linking then took place during liposome extrusion (Chacko et al., 2012). Furthermore, magnetically responsive liposomes containing maghemite nanocrystals or iron oxide nanoparticles have been prepared to release drugs under applied magnetic fields. The molecular nanogel based on liposomes can also be pH-triggered, in which a change in pH leads to the cross-linking formation. After removing the lipid, liposome-based hydrogel particles with potential uses in environmentally sensitive drug release were achieved (Torres-Martinez et al., 2019). Furthermore, liposomes which are composed of one or more lipid bilayer structures can be used to encapsulate drugs. A micelle with a hydrophilic shell and a hydrophobic core was responsible for carrying drugs. Also, the

nanocapsules can be used to encapsulate a drug in their matrix, as shown in Fig. 8.7.

8.3.4 Three-dimensional printing (3DP)

Recently, the 3D printing of bio-based hydrogels and other polymers has been considered a viable path toward ultimate regenerative treatment. The 3D structure allows liquid recognition for developing a swelled hydrogel form. The fluid core may stop the polymer material from failing, presenting features comparable to those of weak tissues. Conventional hydrogel manufacture processes like the mold casting method can only produce simple structures through molds. Thus, it is difficult to prepare drugs with complex structures. 3D printing of hydrogel drugs is gradually increasing, however, the current 3D-printed hydrogel drugs still face some challenges, including poor shape fidelity, limitations in drug type and load, and the requirement for soaking the hydrogels in drug solution (Zu et al., 2022). Hydrogels have been applied in numerous printing systems, such as droplet bioprinting, stereolithography, and two-photon polymerization.

Extrusion-based printing is a common 3DP technique used to manufacture hydrogel constructs using materials that undertake sol–gel transitions including before extrusion, during extrusion, or after deposition (Nele et al., 2020). For example, Pluronic F127 has been used to offer rapid thermal gelation of alginate-based hydrogel systems in extrusion printing. The reversible characteristic of the sol–gel allows its release during electrostatic cross-linking of the alginate component. A similar approach used the reversible thermosetting of gelatin to fabricate interconnected channel

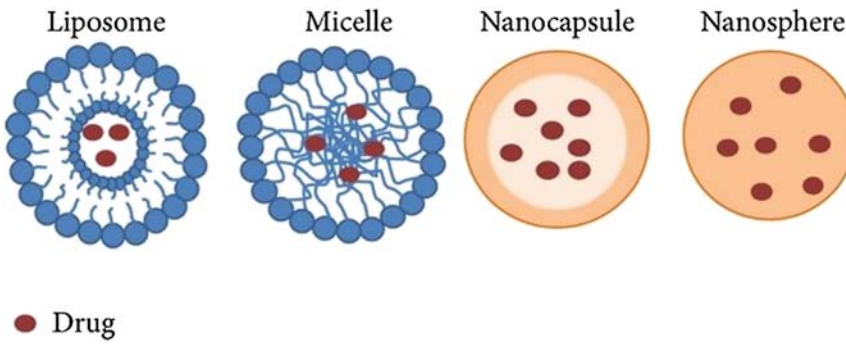

Figure 8.7 Structure of liposomes, micelles, nanocapsules, and nanospheres incorporating a drug in the matrix. *(Reprinted with permission from Neophytou and Constantinou (2015).)*

networks throughout GelMA hydrogels (Ouyang et al., 2022). Another approach is partially cross-linking bioinks into soft and extrudable hydrogels that can be further cross-linked post-printing, typically via photo-cross-linking, such as the hydrogel fabricated from methacrylate-, acrylate-, or norbornene-modified biopolymers (Fig. 8.8) (Ouyang et al., 2017).

Numerous additives have recently been incorporated into hydrogel bioinks to enhance printability or impart additional structural or functional properties. Furthermore, 3D/4D-printed hydrogel capsules have become more attractive for expanding the utility of hydrogel drugs, particularly the design of hydrogel capsules for smart controlled drug release. For example, poly(N-isopropylacrylamide) (PNIPAAM), a thermosensitive hydrogel,

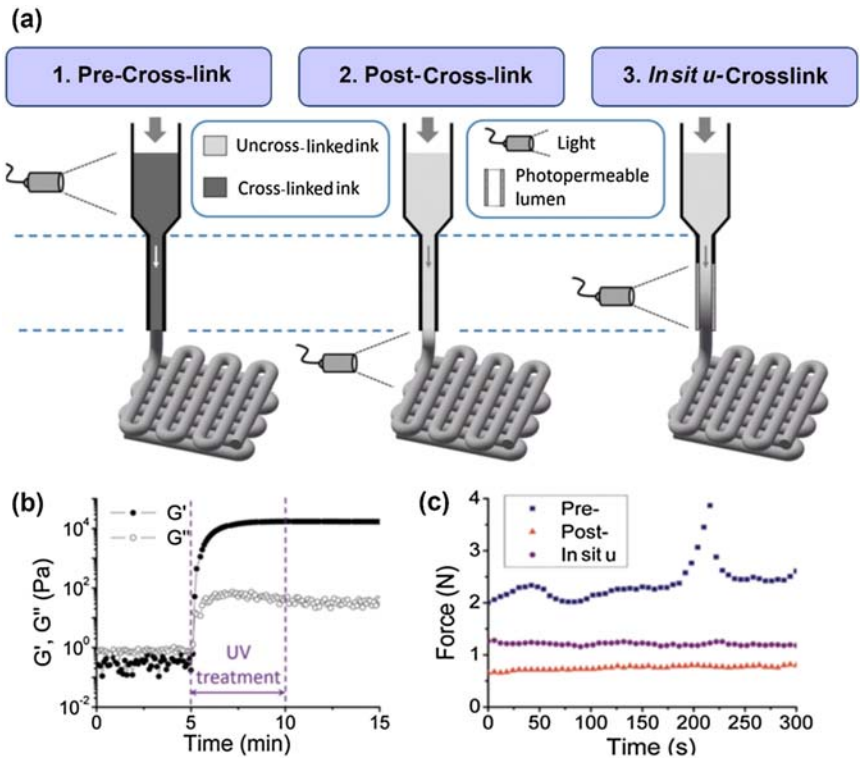

Figure 8.8 (a) Schematic of three different cross-linking strategies for extrusion-based bioprinting photo-cross-linkable inks (5 wt.% MeHA), where cross-linking occurs before (pre-cross-link), after (post-cross-link), or during (in situ cross-link) extrusion; (b) representative curves of storage (G') and loss (G'') moduli during irradiation of 5 wt.% MeHA with UV light (10 mW cm^{-2}); (c) driving force consistency. *(Adapted with permission from Ouyang et al. (2017).)*

was produced via extrusion 3D printing as the capsule shell (Zu et al., 2022). Fig. 8.9 illustrates the 4D/3D printing process for hydrogel.

3DP techniques are a new technology in developing medical devices for drug delivery. The main advantage of 3DP is the custom design, providing ideal devices with less fabrication and postprocessing time, reduced waste material, and lower cost. 3DP is the layer-by-layer deposition of slurry inks

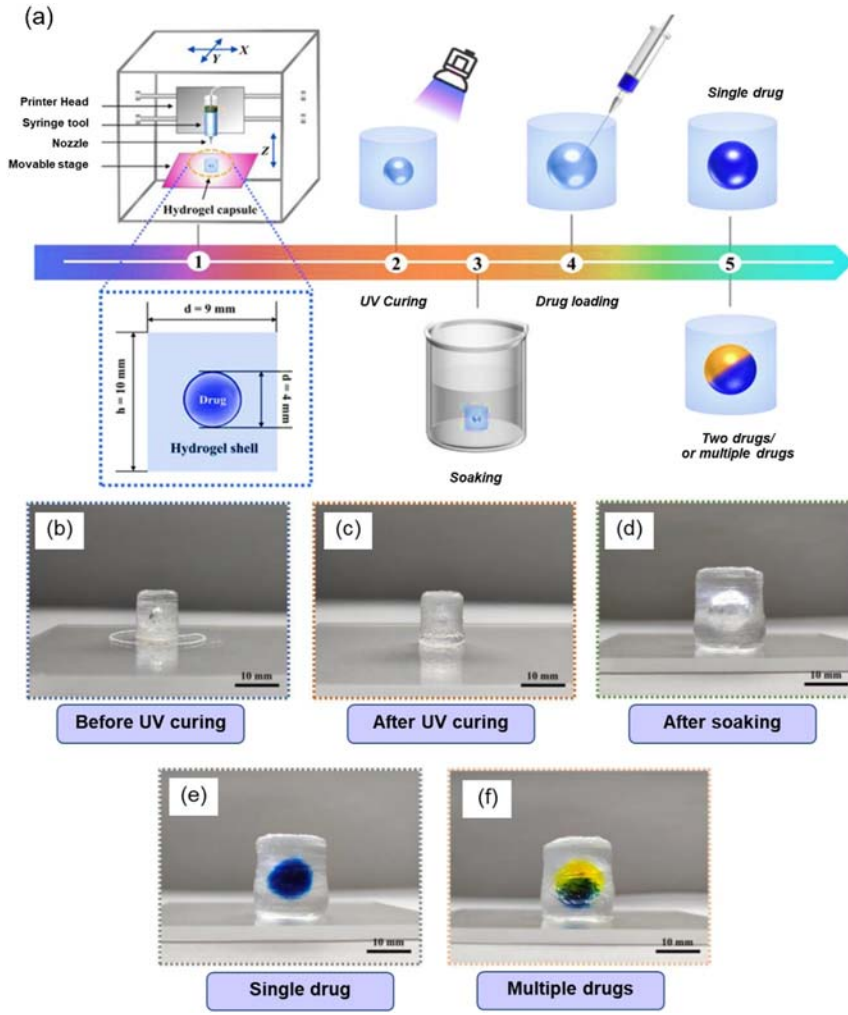

Figure 8.9 (a) Schematic diagram of the 3D-printed hydrogels and photographs of 3D-printed hydrogels, (b) before UV curing, (c) after UV curing, (d) after soaking in water for 96 h, (e) 3D-printed hydrogel loaded with a single drug, and (f) 3D-printed hydrogel loaded with multiple drugs. *(Adapted with permission from Zu et al. (2022).)*

and the burning out of liquid inks to obtain the final shape. Hence, the rheological parameters of the printing ink, viscosity, yield stress, and dynamic elastic modulus are essential for determining the final properties (Gritsch et al., 2021). In addition, 3DP has other vital factors in determining the shape, including nozzle speed and extrusion pressure. The pressure must be sufficient for a continuous strand at the given speed. In addition, the effect of hydrogel fabrication techniques, casting hydrogel (conventional fabrication), and 3D printing hydrogel impact the achieved mechanical properties. For example, 3D-printed chitosan exhibited ductility behavior with a significant drop in strength compared to those of the cast hydrogels due to the less homogeneous structure of the 3D-printed lattice. This can cause weakness in 3D printing due to stress distributions leading to failure, which can be overcome by incorporating higher-strength materials or reinforcements (Zolfagharian et al., 2018). Fig. 8.10 displays an example of 3D-printed gelatin-based hydrogels with designed structures.

8.3.5 Rheological toolbox

Hydrogels are networks of polymers that imbibe a significant portion of water. Depending on the chain stiffness and loadings, they are generally soft, and cross-linking is required to stabilize the network as well as improve the mechanical and rheological properties. When the cross-link density exceeds a threshold, yield stress arises—a representative critical stress at which hydrogels flow if applied stress exceeds this value. There are several approaches to use to measure yield stress but the most common is to use large-amplitude oscillatory shear flow (LAOS).

In LAOS, the frequency is fixed and flow strength—either stress or strain amplitudes—is increased. Taken that the cross-linked hydrogels are

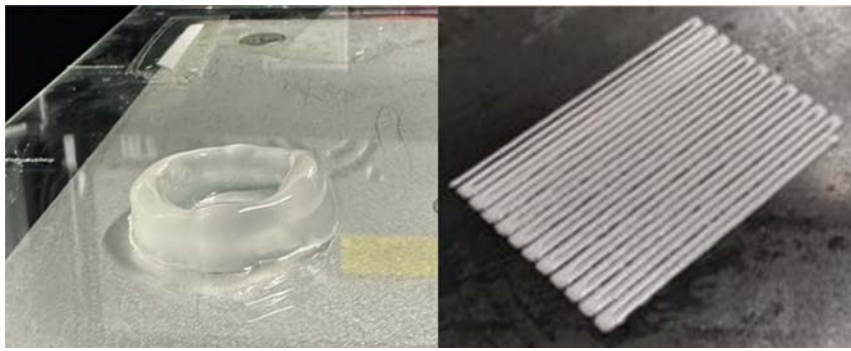

Figure 8.10 3D-printed gelatin-based hydrogels.

solid-like, the on-set amplitude, that is, elastic modulus (G') or the magnitude of complex modulus (G^*) drop, defines yield stress. This on-set splits the amplitude regime into two: (1) low-amplitude regime where the hydrogels exhibit their linear viscoelastic behaviors and (2) high-amplitude regime where nonlinear viscoelasticity arises. As mentioned above, both stress- or strain-controlled tests can be used to estimate the yield stress, but technically, stress-controlled is encouraged as it is a direct measurement and the amplitude spacing can be specified for better resolution (Ewoldt and McKinley, 2017).

Alternating between low- and high-amplitude oscillatory strengths can give an insight into the recoverability. For this, the low- and high-amplitude regimes must be identified first using LAOS, as described above. The test time Δt of each substep and number of repeats can be adjusted to reveal the material properties of interest. For example, this recovery is linked to shape retention of the filament on the substrate in direct-ink writing (Diloksumpan et al., 2020; Corker et al., 2019).

For injectable hydrogels, the steady-state viscosity as a function of shear rate, $\eta\left(\dot{\gamma}\right)$—also referred to as flow curves—can also be reported. However, for cross-linked hydrogels, flow instabilities, e.g., shear banding and edge fracture, can occur in the high shear rate regime. A detailed explanation of such phenomena can be found elsewhere (Divoux et al., 2016).

8.4 Conclusion

Bioresorbable polymers represent a diverse family of biomaterials, which can be absorbed by the body and then disappear when, after healing, the device is no longer needed. Innovative hydrogel products have been developed as carriers for specific applications or biomedical devices, including regenerative medicine, wound-healing dressings, and controlled-release drug-delivery systems. Recently, resorbable hydrogel has been variously applied in controlled-release drug delivery and wound-healing dressings as it can be degraded in the human body and also undergoes time degradation, depending on the materials. Bioresorbable hydrogel can be synthesized by several fabrication techniques. Many hydrogel systems have been developed, and fundamental studies have significantly contributed to understanding this unique class of materials. Many cross-linking methods are currently available to prepare hydrogels. Among these cross-linking methods, the physically cross-linked hydrogels are of greatest

interest, particularly when the hydrogels are fabricated under mild conditions without organic solvents. Although several interesting physical methods are known, 3D printing of hydrogel drugs is gradually increasing. However, some challenges remain, including poor shape fidelity, drug type and load limitations, and the requirement for soaking the hydrogels in the drug solution. It is expected that the current design and fabrication of bioresorbable-based hydrogels used for drug-release applications, along with some representative examples emphasized in this chapter, could further benefit in their development and application for biomedical purposes, in particular drug-release applications.

9.1 Introduction

Molecular modeling is the discipline of numerically depicting molecular structures and replicating their behavior using quantum and traditional physics formulae. Polymer experts are able to directly create and collect molecular data such as energies, geometries, electronic characteristics, spectral characteristics, and bulk characteristics using computer tools. The characteristics of materials are well known to be closely linked to their makeup and bulk condition at the level of the molecular structure. Molecular modeling may be the only technique capable of directly revealing the structure of materials at the molecular level (Zuilhof et al., 2018).

In this chapter, we have made an effort to highlight important recent developments in the discipline of molecular modeling and demonstrate the ideas, techniques, and potential uses for smart polymer-based medication delivery. We propose a road map highlighting the possibilities and constraints of employing reliable multiscale molecular modeling approaches to accelerate the process of improved polymer-driven drug-delivery systems. These computational methods allow forecasts and interpretations of empirically known macromolecular frameworks, interactions, and micro- and macro-material characteristics. Polymer simulations, with recent advances in computational capacity, can educate, guide, and enhance empirical macromolecular component design and discovery activities. We also provide an overview of key design approaches for creating improved

multidimensional polymer structures, highlighting how the unique structure and chemistry of a few polymer-based drug-delivery systems can provide excellent drug-delivery platforms.

The effectiveness of a drug is usually hampered by poor water solubility and short residence time in the body's tissues (Zuilhof et al., 2018). Conventional drug distribution forms have made significant contributions to disease therapy. Several factors have increased the demand for smart transportation methods such as low effectiveness, trouble maintaining drug levels within desired ranges, reducing adverse reactions and toxicities, and the rise of particular biological therapies.

The requirement for better bioavailability, customized transport, long-term action, and other factors motivate the development of innovative pharmacological forms based on established therapeutic compounds. Biodegradable polymers, which are excellent candidates, have been extensively researched in recent years, especially as carriers for renal, long-circulating, and pH-sensitive drugs, in order to enable bone tissue engineering applications (Andreopoulos and Tarantili, 2002; Berendsen et al., 1984; Bourassa et al., 2011). Medication carriers with specific characteristics that are adapted for a given biological target are the foundation of effective medication delivery. Drug carriers with unique qualities that are matched to a specific cellular target are the foundation of effective drug transportation. Three primary qualities can be highlighted, namely:

(1) The ability of a polymer and a medication substance to mix together.
(2) The interactive force among the polymer chain and the drug molecule is identified by the nonbond intermolecular polymer—drug interaction energy.
(3) Polymer chain flexibility to describe the drug molecule's capacity to be coated and protected for prolonged circulation.

The smart polymers are classified broadly into organic and inorganic systems, and by varying their compositions, shapes, dimensions, and surface properties, it is possible to modify the physiochemical features of these systems. Polymer micelles, glycopeptides, etc. constitute the organic category, whereas carbon-, silica-, and silver-based ones fall into the inorganic category.

Computer modeling techniques that are properly evaluated and parameterized can provide the required molecular specifics to develop better knowledge of the process by which the Active Pharmaceutical Ingredient (API) is formulated and supplied.

There are numerous macro-molecular modeling methodologies accessible for application, including quantum mechanics (QM), molecular mechanics (MM), Monte Carlo (MC), molecular dynamics (MD), and other famous methods such as meso scale (MS).

9.2 Methods for molecular simulation for designing polymers

A computational scientist has specific problems when working with the class of complex fluids known as polymers as they display fascinating and important features over an extensive spectrum of scaling range, from the monomer to the polymer's radius of gyration. Numerous software and algorithm breakthroughs, as well as major advancements in computer hardware, have been made to overcome these computational challenges (McCrackin, 1967).

Nowadays, molecular simulation approaches are crucial tools for the computational devising of new material designs as well as for the synthesis and prediction of the structure—property relationships of molecular systems.

The polymer community has faced enormous challenges in the present era due to the search for innovative materials with improved performance, less environmental impact, and/or characteristics that imitate bio-systems (Frenkel, 2013). We have briefly discussed the relevant simulation techniques that are suited for each type of model, but in general, the polymers are MC and MD. The MC methods often incorporate uncorrelated random numbers to comprise a significant number of stochastic computer operations (Piscitelli et al., 2010). It must be noted that MC approaches are not restricted to the atomic size and can be utilized at any level if the appropriate logical model is provided. Three distinct phases are a common component of MC techniques:

(1) Converting the observed physical phenomenon into a comparable statistical model.

(2) Dealing with the derived logical model by numerous numerical stochastic sampling trials.

(3) Statistically examining the informative data. A basic sample method or a weighted sample method can be used as the sampling method. Simple sampling employs random numbers distributed equally, whereas weight sampling creates random numbers depending on the distribution tailored to the subject under investigation.

9.2.1 Simulation with Monte Carlo

This simulation is a potent method for predicting the essential physico-chemical features of complex systems and balancing their dense phases. It is especially well suited for modeling chain-like systems' bulk phases. Early MC simulations were carried out on lattice models because of challenges with eliminated quantity interactions, chain interactions, and conformational firmness (Mavrantzas, 2004), but emerged soon in continuous space. Nowadays, we can broadly divide the MC moves created for polymers as follows:

(1) Simple MC moves
(2) Complex MC moves
(3) Advanced MC moves.

(1) Simple MC moves

Repetition (McCrackin, 1967), libration or flip (Theodorou et al., 2004), dimer flip (Mavrantzas, 2004), concerted rotation (Vacatello et al., 1980), intrachain and interchain concerted rotation (Mavrantzas et al., 1999), general repetition (Peristeras et al., 2005), parallel rotation (Mavrantzas et al., 1999), pivot (Rosenbluth and Rosenbluth, 1955), end-mer rotation atom identity exchange (Dodd et al., 1993), and quantity fluctuation (Lal, 1969) are examples of basic MC moves. These operations are restricted to a lone polymer cycle, and general repetition, configurational bias, and end-mer rotation only work at the ends of the chain.

(2) Complex MC moves

Large interior regions of one or two polymer chains undergo simultaneous dramatic reconfigurations as a result of complex MC motions. They first show as chain-breaking steps (Olaj and Lantschbauer, 1982) in MC simulations of polymers on a cluster, ultimately leading to the discovery of chain connectivity altering moves. The following movements are incorporated in a group of complex MC moves: targeted internal bridging, targeted end-bridging, self-end-bridging, and fusion-scission (Zervopoulou et al., 2001).

(3) Advanced MC moves

Intramolecular double rebridging (IDR) and double bridging (DB) are examples of advanced MC maneuvers (Karayiannis et al., 2002). These are end-bridging move generalizations in that they entail the concurrent or sequential development of two trimer structures (instead of one).

9.2.2 Recent Monte Carlo computer software

These MC moves are available in a few software programs for general polymer design. Readily available MC software include:

(a) Using the enhanced MC code (Halverson et al., 2013) to simulate semicrystalline polymers (Kumar et al., 2017)
(b) Towhee (Martin, 2013)
(c) Cassandra (Shah et al., 2017)
(d) RASPA (Dubbeldam et al., 2016).

In recent years, Chameleon, one of the latest simulation programs in C++ with many chains, was presented by Alexiadis et al. (2019). This new tool can characterize polymer structures including polyethylene (PE), polyvinyl chloride (PVC), and polystyrene (PS) using either an all-atom, united-atom, or coarse-grained framework. It can also handle a wide range of polymer schemes, such as straight and branching polymers. DICE, an MC technique for molecular modeling of large stretchy molecules, has been updated by Cezar et al. (2020) for solute–solvent systems in the liquid or gas phase. This version is based on a more effective use of the configurationally biased move.

MC was used by Dodd and Jayaraman (2012) to examine the effects of polydispersity on the arrangement of polymers on rounded surfaces. They looked at the distribution of free-end monomers inside the grafted layer as well as the shape of the grafted polymer chains and the thickness of the layer created.

Based on single-chain Metropolis MC simulations, Tzounis et al. (2017) proposed a method for computing the unperturbed chain measurement of any polymer chain, independent of its chemical or architectural complexity.

Mendonça et al. (2016) developed the configurationally biased MC method as a replacement for the dissipative particle dynamics (DPD) technique to investigate hassle between grafted polymers with suitable solvents. The primary finding was that the shear force at which slip occurs decreased significantly with the flexibility of the polymer layer.

The tensile blob was previously supported by MC simulations of long, single linear polymer chains stretched uniformly by Pierleoni et al. (1997).

Metropolis MC has now developed into a potent computational tool that is capable of addressing many physicochemical aspects of genuine polymers (structural, conformational, thermodynamic, and morphological) with surprising precision.

9.2.3 Molecular dynamics

Despite the limitless potential of MC, the technique still needs to address some flaws and problems to mature to the same degree as molecular dynamics.

For the most part, "molecular dynamics" is effective at simulating systems with many atoms, such as polymers. The benefit of MD is that it can quickly determine a system's dynamics by analyzing the motion of its atoms according to classical mechanics.

MD simulation, which initially appeared in the late 1970s, has progressed from demonstrating a few hundred atoms to biologically relevant systems; totally dissolved proteins with distinct solvent representations, membrane-embedded proteins, or massive macromolecular structures like nucleosomes or ribosomes are examples of these types of structures.

In particular, the advantage of MD simulations is that they can directly and quantitatively predict both the structure and dynamic features of a molecular system.

Newton's second rule governs each atom's motion in atomistic MD simulations (aMDs), making it possible to determine each atom's position as a function of time. Simulations can be used to improve structures, identify the attributes at equilibrium states, and/or comprehend the dynamic behavior of the system.

A typical straightforward MD algorithm's flowchart shows the steps listed below (Binder, 1995):

1. The method begins with the selection or building of a configuration that reflects a molecular-level snapshot of the relevant physical system (starting locations and velocities of each particle inside the system).
2. After that, the total force exerted by the system's particles is calculated.
3. Using the proper methodology, integrating the motion equations follows.
4. Measurements are made with accuracy (velocities, positions, energies)
5. When the central loop is complete, the mean of all of the quantities and the necessary characteristics are calculated and printed (N steps).

$$m_i\ddot{\mathbf{r}}_i \equiv m_i\dot{\mathbf{q}}_i = \mathbf{F}_i$$

where $\mathbf{F}i$ represents the force pulling on atom i. Differential equations of second order in 3N are then used to solve motion equations.

The following elements (Binder, 1995) need to be taken into account while choosing an algorithm:

- The algorithm should not necessitate an excessively high volume of force evaluations for each integration time step.
- The algorithm needs to adhere to the energy conservation law.
- The algorithm ought to allow for the usage of a big-time step dt.
- The algorithm should run quickly and use little memory.

An MD simulation's primary goal is to predict thermodynamic parameters as time averages and determine temporal correlation functions that are descriptive of the dynamics, not to trace the precise configuration of a system over a lengthy period of time.

In the field of research and development, quantum ATK polymer simulator software is used to create polymers with enhanced thermal conductivity, thermomechanical and optical properties for products like photo-resist, transparent polymers, rubber-like polymers for tire manufacturing, along with thermoset polymers for the insulation industry. Quantum ATK's polymer construction and equilibration tools create trustworthy polymer models, which can subsequently be simulated utilizing fully automated processes and an MPI parallelized MD engine.

9.3 Applications of the polymer-based smart nanocarriers

Polymer particles have shown their usefulness in maintaining and keeping drug molecules safe, including proteins and DNA molecules against degradation caused by various environmental hazards (Kawashima, 2001). Thus, these polymers offer different possibilities for the delivery of proteins and genes. There are many ways to make nanoparticles, dependent on the polymer's physical and chemical characteristics, as well as the active component (Panyam and Labhasetwar, 2003). The aspects that need to be taken into synergistic account for a smart, regulated delivery system are listed in Fig. 9.1.

Trying to classify nanocarriers precisely is a daunting task. Since there is no clear boundary between the biomedical and pharmaceutical nanotechnology fields, different viewpoints may be relevant. They can also be categorized based on where they came from, such as natural or synthesized polymeric nanoparticles. Since they simultaneously perform polymer design and colloidal measurements (1000 nm), these are usually identified as polymer nanoparticles (biodegradable and biocompatible), nanoemulsions,

Figure 9.1 . Multiple variables must be taken when building a polymeric nanoparticle for a smart drug-delivery system.

dendrimers, polymersomes, polymer micelles or complexes, or cubosomes (Li et al., 2016). Polymer drugs, polymer–drug conjugates, polymer–protein conjugates, polymer micelles (drugs covalently bound to polymer carriers), and complexes (designed as nonviral vectors) are all examples of polymer therapies (Lal et al., 2022). Materials are selected for the creation of polymer-based nanocarriers not only for their biological behavior but also for their functional qualities, such as their capacity to construct designed nanostructures. Biocompatible and recyclable polymers are generally preferred.

Large numbers of available and/or easily synthesized polymers with good potential are used in medicine, while only a few have achieved regulatory approval (Lal and Verma, 2021). In order to increase medication specificity and decrease systemic toxicity, a number of nano-drug delivery systems have been created and assessed. They are now thought to be the most common and promising methods. For the treatment of cancer and other inflammatory illnesses, nanocarriers employ increased permeability and retention (EPR) to selectively concentrate at areas of disease. To progress toward more advanced nano drug-delivery systems (DDSs), research has focused on improving the performance of polymer carriers by developing smart, stimuli-responsive nanocarriers (SRNs). Such carriers change their composition as a result of internal or external stimuli, leading to dissociation of the carrier and release of the drug, based on

pharmacokinetics and pharmacodynamics when reaching the site of action after administration (Kawashima, 2001). The pH and presence of certain enzymes within cells or inside the pathological microenvironment are the two most significant and commonly used internal stimuli. Reduced glutathione stimulating hormone in the cytosol is also extensively utilized in the development and manufacture of reduction-sensitive polymer nano DDS (Cui and Mumper, 2002).

These multifunctional polymeric nanocarriers can solve current nanoparticle-based drug formulation problems, such as drug formulation and encapsulation, long-term stability, cell internalization, site targeting, increase in cellular uptake, intracellular targeting, and drug release. These double- and multi-activation response properties provide exciting new control over drug-release kinetics with improved efficacy (Cao et al., 2001). Due to their nonbiodegradable carriers, poor encapsulation, and unsuitability for clinical therapy, all mentioned studies of stimuli-responsive dual and diverse drug-delivery systems are primarily trial-and-error models. Fig. 9.2 provides descriptions of dual-response and multiple-response nanoparticle systems. It should be emphasized that the stimulus and the response occur simultaneously in the same place or in different ways (Kreuter, 1994). This multi-stimuli-responsive polymeric nanocarriers have the ability to regulate drug-release profiles and enhance anticancer effectiveness in both in vitro and in vivo models, while also allowing control of nanocarrier formulation and drug loading under controlled conditions. We briefly discuss a few cases in this section (Kasagana et al., 2011).

In particular, dual-response triblock copolymers functionalized by raising the temperature and remaining below the decreasing critical solution temperature followed by cross-linking have been developed as multifunctional nanoparticle systems for drug delivery that is sensitive to reduction and temperature (Lal et al., 2021). These multifunctional nanoparticle systems are triggered by a reduction—oxidation mechanism that causes the decross-linking, disruption, and disintegration of the nanoparticle system, which releases the active components. These nanoparticle systems have been developed to target cancer cells.

For greater drug release and accumulation in cancer targets, multifunctional disulfide cross-linked micelles with dual pH/redox stimulation have been generated. Intracellular pH and the redox environment of cells/lysosomes facilitate drug release (Lal et al., 2017).

Improved biodegradable as well as biocompatible, nonimmunogenic, and nontoxic smart polymer nanoparticles, capable of effectively capturing

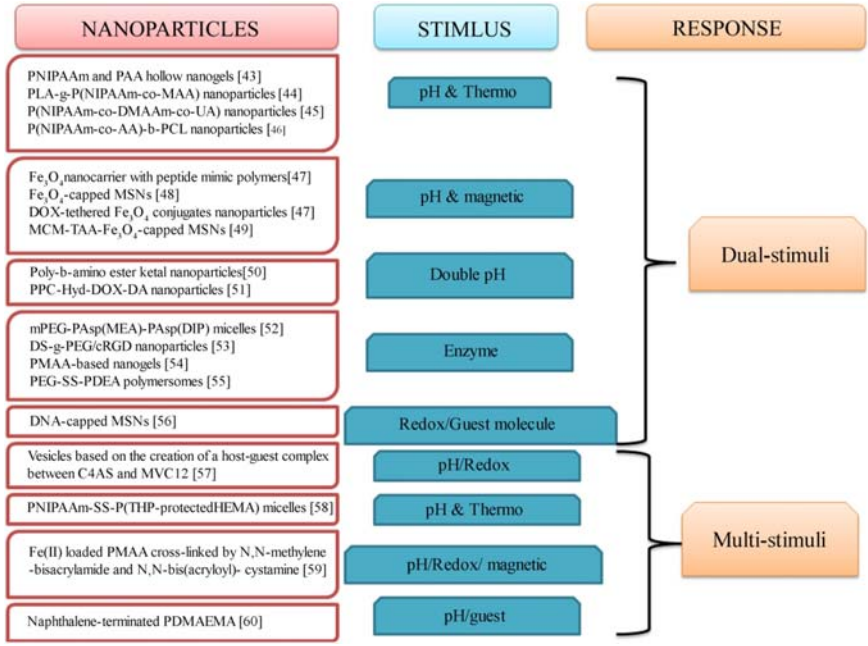

Figure 9.2 An overview of materials that respond to dual or multiple stimuli for nanocarriers used in several smart drug-delivery systems.

and maintaining the release of drugs into the systemic circulation, improving the accumulation of cancer targets, and with effective release kinetics in response to external or internal stimuli are the immediate targets to overcome any adverse conditions (Lo et al., 2005). In addition, smart polymer nanoparticle technology does not cause any collateral damage or damage to healthy cells. To determine the actual mode of action of anti-cancer targets, clinical studies of dual and multiple stimulus—response systems are needed. Additionally, smart nanoparticle systems with dual and multiple stimuli responses are bound to show promise in cancer treatment. This will consist of targeting ligands and nanoparticles responsive to dual/multiple stimuli to treat multidrug-resistant cancers through site targeting, site-specific delivery, and rapid or sustained release (Zhang et al., 2011; Loh et al., 2012). Fig. 9.3 presents images describing responsive nanocarriers.

The development of smart stimuli-responsive nano DDSs is an important new area of drug delivery. The most extensively studied concern endogenous triggers (enzymes, pH, and redox potential) that exploit certain intracellular or microenvironmental conditions present at the diseased area to accomplish controlled drug release (Heller, 1984). In addition to

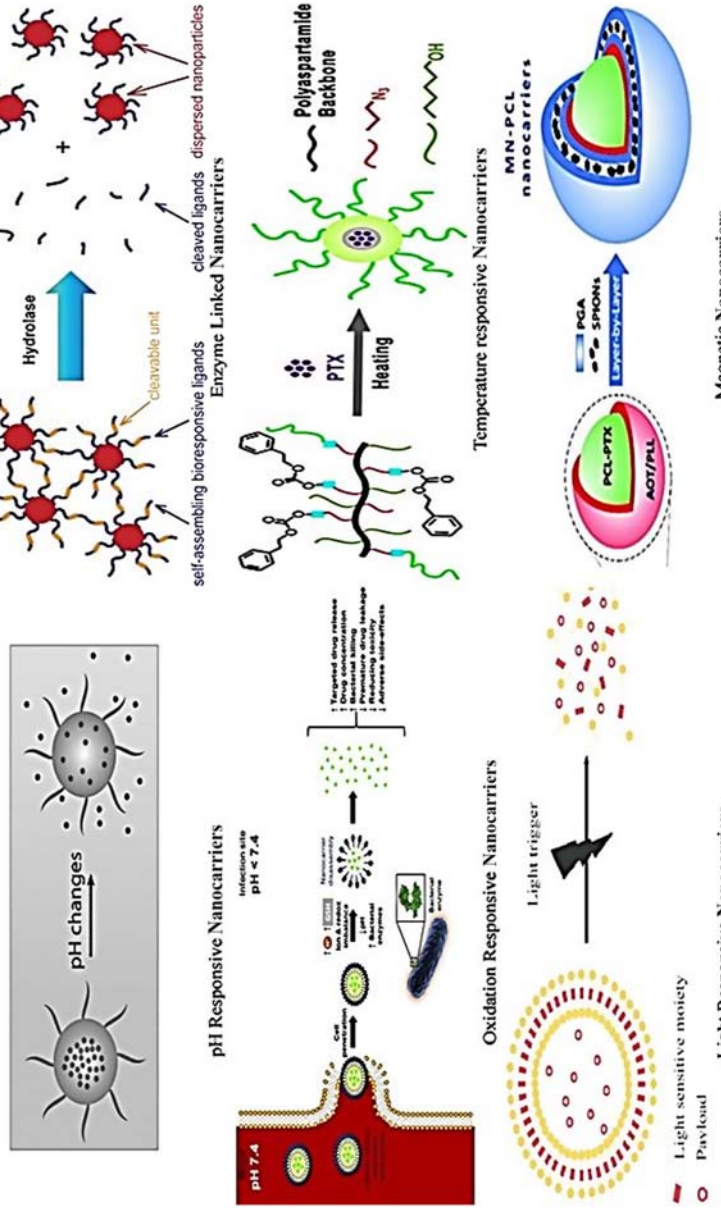

Figure 9.3 Different types of responsive nanocarriers.

endogenous stimuli, there is a growing interest in externally applied stimuli, often using methods currently used clinically for other purposes, such as ultrasound and magnetic fields. Despite the fact that this strategy appears to be promising, the main problem is coordinating drug accumulation with the application of exogenous stimuli with sufficient force to initiate drug release (You et al., 2003).

This approach is frequently used in conjunction with imaging methods to detect the distribution of nano DDS bodies, resulting in effective companion diagnostics similar to those already existing in the clinical setting. The development of personalized or patient-centered therapies could benefit from this strategy. New methods are needed to enable classification of patients and to identify those who may benefit from specific treatments due to patient heterogeneity (Tyle and Agrawala, 1989). To achieve site-specific drug release, probes for molecular imaging are activated under specific triggers with intraindividual, interindividual, and cell-to-cell variability, the application of stimuli-responsive DDS is essential. Therefore, they can be used to identify functional biomarkers needed to predict treatment effects (Schmaljohann, 2006).

Table 9.1 presents recent development program in the creation of smart nano DDS. Most of the research published till date remains proof-of-concept work, and the safety and efficacy of these nanocarriers in vivo have yet to be determined.

9.3.1 The era of smart polymer revolution

Resins known as smart polymers (SPs) change or respond in a particular manner to their surroundings. Since they are composed of polymers, even the slightest environmental changes cause them to react drastically. The terms "stimuli-responsive polymers," "intelligent polymers," and "environmentally sensitive polymers" are also used to describe them. What basically makes these polymers stand out as "smart" materials is their exceptional ability to react to extremely minute changes in their surroundings. These SPs are "smart" because they can modify their physical shape in response to stimuli with slight environmental changes, such as changes in pH or temperature, increases in ionic strength, the presence of particular metabolic chemicals, the inclusion of an opposite-charged polymer and the formation of polycation–polyanion complexes, and changes in an external force and alterations in a magnetic and electric field, radiation forces, or light (Vargas et al., 2018).

Table 9.1 List of responsive nanocarriers with respect to their functional attributes.

- **pH-responsive nanocarriers**

Dependent: pH

Example: Anticancer drugs are released selectively, taking into account the temporary or persistent acidity of tumors and areas of inflammation as compared to normal (Kato et al., 2013)

Mechanism: Based on two approaches:

1. In the initial strategy, either a pH-sensitive polymer is applied, or it degrades, resulting in the release of the drug, or the change in pH causes a change in the physicochemical properties (i.e., polarity) of the polymer, which destabilizes the nanocarrier and leads to the simultaneous release of the drug
2. Using an acid-cleavable linker, the drug is affixed to the polymeric base (Erdmann and Uhrich, 2000; Pang et al., 2016)

- **Enzyme-responsive nanocarriers**

Dependent: Catalytic activity of enzymes

Examples: Biocatalysis, sensing, imaging, controlled drug release and diagnostics (Gendelman et al., 2015)

Mechanism: Based on two approaches:

- Enzymatic transition is dependent on the nanocarrier itself

In enzyme-activated solutions, surface modification of nanocarriers with molecules results in modifications to the carrier's physical characteristics (Lammers et al., 2012; Zhao et al., 2018)

- **Oxidation-responsive nanocarriers**

Dependent: Redox potential variations between the outside of the cell and inside the cell habitat

Examples: Proteins, siRNA, intracellular DNA, low-molecular-weight drugs, and cancer treatments (Phillips and Gibson, 2014)

Mechanism: Based on two approaches:

The main components of these systems are cationic polymers, which can link DNA and siRNA to form complexes, and disulfide cross-linkers, which are specifically reduced inside the cell and lead to the cargo release and transfection efficiency (Cai et al., 2015; Wang et al., 2011b)

(Continued)

Table 9.1 List of responsive nanocarriers with respect to their functional attributes.—cont'd

- **Temperature-responsive nanocarriers**

Dependent: Temperature fluctuations instead help with self-assembly rather than drug release
Example: Cancer treatments (Jochum and Theato, 2013)
Mechanism: When a drug is encapsulated, local hypo/hyperthermia allows for its release. This results in a modification of the temperature-sensitive polymer's state and the dissociation of the micellar structure (Hu et al., 2015)

- **Light-responsive nanocarriers**

Dependent: Photoresponsive response to irradiation
Example: Precise spatial and temporal application (Linsley and Wu, 2017)
Mechanism: Azibenzene and o-nitrobenzyl are the two most often employed photosensitive compounds. Polymeric micelles and vesicles that enable release upon illumination have also been produced using photosensitive moieties including copolymers, owing to polarity shifts (Marturano et al., 2017)

- **Ultrasound-responsive nanocarriers**

Dependent: One option is to use ultrasound to facilitate drug release from nanocarriers
Examples: Tumor regression and reduced cardiotoxicity (Xia et al., 2016)
Mechanism: Ultrasound waves cause oscillating bubbles to form, which eventually burst, disrupting the polymer assemblies nearby. According to reports, using ultrasonic to biodegradable polymers may speed up the process of disintegration (Concellón et al., 2016; Ulbrich et al., 2016)

- **Magnetic-field-responsive nanocarriers**

Dependent: Paramagnetic or superparamagnetic nanoparticles are used to create magnetically responsive nanocarriers within a polymeric vehicle (Revia and Zhang, 2016)
Example: MRI (image-guided drug delivery), incredibly effective at destroying cancer through hyperthermia (Baeza et al., 2012)
Mechanism: It can function as a dual therapeutic agent, releasing drugs through the dissociation of nanocarriers and destroying cancer cells through hyperthermia (Yigit et al., 2012)

Electrical currents caused smart polymers to very quickly change their viscosity. The phrase "smart polymers" was first used in this context, and applications of environmentally sensitive polymers were assessed (Pan et al., 2012; Linsley and Wu, 2017; Galaev and Mattiasson, 1999). The key advantages of smart polymers are their simplicity in production, ability to maintain medication stability and level within the therapeutic window, and ability to promote patient compliance. Targeted drug-delivery systems, tissue engineering, microfluidic processes, gene carriers and bioseparation, reversible biocatalysts as actuators, protein folding, and several more important applications are just a few examples of the pharmaceutical industry's utilization of these technologies.

Scientists are currently chemically forming novel polymeric materials that can sense specific changes in the environment in biological systems and modify them reliably. These materials could be used as instruments for delivering medications or controlling other metabolic mechanisms (Gil and Hudson, 2004).

Smart polymers are simple to make, can be administered in situ as a liquid that gels at body temperature, are excellent carriers for providing nutrients to cellular and products from cells, can be readily changed with cell adhesion ligands, and are used for blood-contacting applications. They also improve patient cooperation, maintain drug stability, keep the drug level in the therapeutic range, and are nonthrombogenic, biocompatible, robust, pliable, and tough (Kumar et al., 2007). However, these polymers do have significant drawbacks, including the fact that they are frequently mechanically fragile and challenging to load with cells and medications.

Drug delivery is just one application for smart polymers. They are particularly well suited for bioseparations because of their characteristics. By utilizing smart polymers that change quickly and reversibly as a result of an alteration in the characteristics of the medium, the time and money required to purify proteins may be greatly decreased. Another approach for controlling biological reactions with smart polymers is to create recombinant proteins containing integrated polymer-binding sites adjacent to the ligand-binding sites. The technology of self-adaptive wound dressings depends greatly on smart polymers (Linsley and Wu, 2017; Zardad et al., 2016).

According to a published study, the dressing design uses patented, highly absorbent synthetic smart polymers that are immobilized in a matrix of three-dimensional fibers. Hydrogel is also incorporated into the material's core to provide additional hydration functionality.

One of the best examples of a thermally reversible, multifunctional polymer that is soluble-insoluble is poly(N-isopropylacrylamide), along with PNIPAAm, which, in an aqueous solution, has a lower critical solution temperature (LCST) of 32°C (Concellón et al., 2016; Galaev and Mattiasson, 1999).

9.3.1.1 Classification

The classification of smart polymers is as follows:

(I) "Smart" polymer categorization based on structural conformation

The triggers that cause the reaction or the type of conformation chosen for their application can both be used to categorize SPs. Many SPs can be described as:

(1) Chain-free state in the solution
(2) Trans-linked hydrogels
(3) Chains mounted on a surface, depending on their physiochemical makeup and distinctive structural traits.

(1) Chain-free state in the solution

SPs offered as a chain-free state in the solution are typically integrated into water-based systems. Two phases can be seen forming inside the system when these polymers are subjected to their stimuli. When external cues, such as temperature, are applied, the polymer-free chains of relevance in this class show reversible morphological changes. Thus, the motivation behind PNIPAAM's behavior appears (Hoffmann et al., 2002) in poly(ethylene oxide), poly(ethylene glycol), poly(propylene oxide), and poly(N-vinylcaprolactam). The bioprocessing application that employs SPs with this physical form most frequently is the production of ATPS.

(2) Trans-linked hydrogels

A hydrogel is a network of chains in three dimensions comprised of hydrophilic polymers, some of which are solvated by water atoms and others which bond together chemically or physically. Poly(2-hydroxyethyl methacrylate) (PHEMA) hydrophilic networks were proposed by Wichterle and Lim for use in contact lenses and the hydrogels used in the biomedical sector (Liu and Urban, 2010). In reaction to alterations in environmental stimuli, hydrogels with SPs in their structure can "swell" and then "deswell" or contract. The use of hydrogels has previously been

limited to the biomedical sector (i.e., drug delivery). New SP generations, however, may allow for the expansion of its application into new fields such as bioprocessing. Polymeric materials, both synthetic and natural, have been used to engineer a variety of hydrogels. For instance, some of the most well-known natural biopolymers include gelatin, chitosan, hyaluronic acid, alginic acid, and dextran. The most widely utilized natural polymer is chitosan (Zhou et al., 2013).

(3) Grafted chains on a surface

Chain-absorbed conformation, also referred to as "smart brushes" or "smart surfaces," is a category where polymers are covalently connected to the support (Da Silva et al., 2007). There are two possible reactions when these SPs come into contact with their stimuli: either the chains spread out while exposed, or they fall over the support.

(II) Sorting of "smart" polymers based on their activating stimuli

Stimuli-responsive polymers are capable of changing their structural characteristics in regarding to modifications in environmental factors such as pH, temperature, solvent, salt ionic strength, light field, and electrical field. Recent research has focused greatly on stimuli-responsive polymers because of their inventive response characteristics. They have been frequently used as drug-delivery carriers, coatings, membranes, synthetic organs, sensor technology, etc. All-atom molecular dynamics (AAMD) was one of the techniques that was introduced followed by coarse grained molecular dynamics (CGMD), and other methods that gained immense popularity were DPD and MC (Hu et al., 2014).

When studying the single-chain behaviors of stimuli-responsive polymers, AAMD was typically used; however, for larger block copolymers and blended systems, recent modeling developments, including simulations of temperature-, pH-, solvent-, and photo-responsive polymers, have been presented in order to understand the conformation transitions of stimuli-responsive polymers (You et al., 2016). The mechanism at the molecular level and theoretical framework for building intelligent materials may be provided by multiple scale modeling and simulations of stimuli-responsive polymers. Below, various simulation techniques are discussed, such as MC, DPD, AAMD, and theoretical techniques. The outcomes of simulations with stimulus-responsive polymers are then assessed in response to various stimuli (Appold et al., 2017).

9.3.2 Multiple scale simulations of sensitive polymers

9.3.2.1 Polymers with a pH response in simulations

The stimuli-responsive polymers known as pH-responsive polymers can alter in conformation and property in response to variations in the solution pH. The majority of pH-responsive polymers have ionizable groups, which can collect or release protons in response to modifications in the pH of the surrounding environment. Weak bases and acids like carboxylic acids, phosphoric acids, and amines are examples of commonly ionizable groups that change their ionization state when the pH changes (Ulbrich et al., 2016). DDSs, antifouling coatings, intelligent membranes, biosensors, super-hydrophilic surfaces, and other applications have all made extensive use of pH-responsive polymers. A polymer with pH sensitivity is assumed to have a fixed charge at each pH condition in the majority of molecular simulation studies (Hao et al., 2019; Lin et al., 2017). According to the observations of Longo et al., the charge variations are disregarded in applications. One way to solve this issue is to codify the charge regulation process brought on by proton fluctuations using statistical mechanical perturbation theory (Longo et al., 2019). Silva and Jonsson, in contrast, used semiquantitative analyses and MC simulations which are based on perturbation theory to investigate the charge-regulating protein interactions with polyelectrolytes (Gan et al., 2000). Their findings emphasized the significance of the charge regulation system and quantified when the ion−dipole term or charge control dominated the complexation. These techniques could be used to research pH-responsive polymer systems in the future.

A hydrophobic core with many functional groups that can be ionized can give or take protons as a result of pH variations is a pH-responsive SP. The ionization of pH-responsive polymers can cause a variety of structural alterations. Polyacrylic acid (PAA) is the widely recognized pH-responsive SP that has been the subject of most research.

Mesoscale modeling method DPD has been extensively used to comprehend how they change behavior under various pH environments. For example, the self-assembly of amphiphilic copolymers (PAE-g-PEG) found in vesicles, as well as the chemical load and release of doxorubicin drug molecules at various pH environments, have been widely investigated using DPD and MD models (Shao et al., 2012). It should be noted that the polymers in these DPD and MD models have set charges based on the pH level condition, which overlooks charge fluctuation in actuality. Nonetheless, these molecular modeling findings provide a quantitative grasp of

the pH-responsive polymers' controlled drug-release patterns at the molecular level.

Polymers with temperature response in simulations

Since temperature changes are very simple to achieve and to manage in both internal and exterior settings, temperature is a stimulus that is employed most frequently in stimulus-responsive polymer systems. Upper critical solution temperature (UCST)/lower critical solution temperature (LCST) are typically present in temperature-responsive polymers (Ramos et al., 2011). Since UCST polymers are rather uncommon, we concentrate mostly on the explanation of LCST polymers in this section. Water and the polymer would be mixable at temperatures below the LCST, forming a highly inflated, coil-like chain configuration, demonstrating hydrophilicity; at temperatures above the LCST, the polymer chain contracts and curls and additional phase separation takes place, demonstrating hydrophobicity (Ashraf et al., 2016).

The thermos-responsive polymer poly(N-isopropylacrylamide) is among the most common (PNIPAM). Amide groups (-CONH) and isopropyl groups (-$CH(CH_3)_2$), which are hydrophilic and hydrophobic, respectively, make up PNIPAM. At roughly 32°C, the LCST of PNIPAM is close to the temperature of the human body (305K). The structure of PNIPAM changes when the temperature crossed the LCST in an aqueous solution. As a result, drug-delivery systems frequently use it (Deshmukh et al., 2014). Using a variety of force-fields over the past 10 years, on an atomic scale, molecular dynamics simulations were utilized to investigate the coil-to-globule transition of PNIPAM (Li et al., 2014).

Polymers with a photo-response in simulations

Among the most thermos-responsive materials is a type of intelligent material known as photo-responsive polymers which use light to induce changes in color, chemical polarity, and conformation (Darvishmanesh et al., 2015). They have the advantages of environmental protection, remote controllability, and transitory qualities over other stimuli-responsive polymers. Hence, the usage of photo-responsive polymers in materials science has increased recently. Azolbenzene, stilbene, spiropyran, and other light-sensitive compounds are frequently found in the most researched light-responsive polymers. The photo-mechanical capabilities of the photo-responsive polymer azobenzene were studied by Choi and colleagues (Choi et al., 2018). There is a possibility of azobenzene moiety isomerization

having a significant impact on the orientation and conformity of the PRPN material, according to the results of AAMD simulations of the nanocomposites reinforced with gold nanoparticles, which showed that as the isomerization ratio increased, the rigidity and melting temperature decreased (Quan et al., 2016).

Simulations of other responsive polymers

Other responsive polymers, such as salt-responsive, electro-responsive, and dual-responsive polymers, have also been examined through computer simulations in addition to those described above. Ionizable groups are found in a class of polymers called salt-responsive polymers (Chen et al., 2019).

With the addition of saline ions, these polymers' solubility and conformation can adapt to the ionic strength in solutions. Dual-responsive polymers have drawn increasing interest in recent years because some applications may call for a combined response to several stimuli (Hao et al., 2019; Longo et al., 2019).

Dual-responsive polymers have been commonly used, and these include those that respond to heat, salt, and pH, and others (Chen et al., 2019). Using CGMD models, Liu et al. looked into the diblock copolymers PAAPDMAEMA's thermos-responsive and pH-responsive characteristics in aqueous liquids. They found that the molecular weight of PAA-PDMAEMA appeared to have a greater influence on the behavior of aggregation than did the makeup of the polymer (Han et al., 2014). Chen et al. examined the switching behavior of nanopores changed with double-responding block polymers using DPD models (PNIPAM and PAA). The influence of block proportion, chain length, grafting density, and block succession on a nanopore switching effect was thoroughly investigated. The findings showed that under different circumstances with high grafting density, medium block ratio and proper chain length, the wall-PNIPAM-PAA block pattern alone could accomplish the switching effect of nanopores (Chen et al., 2019). These publications have been valuable tools for further computer modeling studies on dual-responsive polymers.

9.4 Conclusion

Through the lens of advances in predictive modeling-led design, we have examined and investigated the most recent thrilling developments in smart multifaceted polymer-based nanoparticles (NPs). We discovered some major challenges and opportunities for future study, and we hope that our

findings will motivate more modeling-guided research into the synthesizing, self-assembly, and uses of smart polymer-based NPs. Because of the rapid advancement of computer technology, computer models such as CGMD, DPD, AAMD, and MC have been widely used to investigate the conformation transformations of stimuli-responsive polymers produced by external cues at the molecular level. External cues can be readily replicated by changing the ambient temperature, solvent setting, force field of view, or bonded properties. As a consequence, multiscale modeling and simulation have evolved toward effective methods for investigating stimuli-responsive materials at the micro- and mesoscopic levels, which could aid in the creation of innovative smart materials while reducing the expense and duration of experiments. A mixture of simulations and trials would help future studies into more complicated stimuli-responsive systems.

CHAPTER 10

Electrospinning technique: A potential method to develop bioresorbable-based medical devices

Senthilkumar Nangan[1], Natesan Thirumalaivasan[2] and Ramasubburayan Ramasamy[3]

[1]Department of Chemistry, Graphic Era (Deemed to be University), Dehradun, Uttarakhand, India; [2]Department of Periodontics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences (SIMATS), Saveetha University, Chennai, Tamil Nadu, India; [3]Marine Biomedical Research Laboratory & Environmental Toxicology Unit, Department of Prosthodontics, Saveetha Dental College and Hospitals (SIMATS), Saveetha University, Chennai, Tamil Nadu, India

10.1 Introduction

Over the past few decades, there has been profound research and development in nanotechnology, leading to remarkable breakthroughs. The creation of nanomaterials using electrospinning technology has gained immense recognition because of their superior qualities, bringing about transformative effects in various sectors, especially healthcare (Abadi et al., 2022). According to data from "Research and Markets," the global nanofiber industry is expected to reach a value of one billion U.S. dollars in the future. The electrospinning technique, an adaptable and uncomplicated method for producing fibers at the micro and nano levels, showcases the vast potential of this field and adds to its flourishing progress (Zulkifli et al., 2023). The fusion of electrospray and spinning methodologies has given birth to the adaptable technique called electrospinning (Schneider et al., 2021). By subjecting a fluid droplet—whether in the form of a solution or melt—extruded from the tip of a die (serving as an electrode) to a robust electric field, the droplet undergoes deformation. This intricate sequence results in the emission of a charged jet from the apex of the cone, propelled toward the opposing electrode. This intricate yet efficient process leads to the creation of uninterrupted fibers. Distinguishing characteristics of electrospinning encompass the production of exceedingly thin fibers, frequently

on a nanoscale, possessing extensive surface areas, adaptable utility for diverse applications, exceptional mechanical properties, and a straightforward procedural essence, all of which have been affirmed by domain experts (Abadi et al., 2022).

Electrospun nanofibers have received significant interest for a variety of uses. These include functional fabrics, specific clothing, skincare products, cosmetics, electronics, sound management, composite materials, filtration systems, and medical tools (Fadil et al., 2021). While electrospinning was primarily used for air purification and protective clothing, its applications have widened over the years. It has found utility in areas like healthcare, water purification, sturdy composite materials, lightweight structures, noise reduction, energy production and storage, photonics, electronics, and wearable gadgets. Particularly in the bioengineering and biomedical fields, there is a notable similarity between electrospun nanofibers and the fibrous matrices present in human tissues (Si et al., 2023). In biomedicine, these nanofibers provide numerous benefits such as a vast array of polymer choices, precise substance release controls, small fiber diameter, large surface area, and customizable pore designs. Electrospinning allows for the design of three-dimensional nanofiber structures that resemble the natural extracellular matrix, making it especially beneficial for chronic wound treatment and tissue engineering (Jin et al., 2018).

Recently, the equipment used for electrospinning has transformed from simple lab setups to viable market solutions. Manufacturers, by adapting and innovating conventional methods, have greatly enhanced the production effectiveness of products derived from electrospinning. Such advancements now make it simpler to produce nanofiber items through electrospinning. Notably, the medical domain has witnessed substantial advancements in creating nanofiber membranes using electrospinning. These materials, having secured patents, have also made their way into large-scale commercial production. They play various roles in medicine, including being used in surgical implants, wound care, and different medical instruments. This section delves into the core techniques of electrospinning, the production of nanofibers, and their diverse applications in the realm of medical equipment (Wang et al., 2021).

10.2 Fundamentals of electrospinning

Over the past decade, electrospinning has emerged as a pivotal technique for producing polymer nanofibers smaller than a micron. Achieving this is

notably difficult using conventional mechanical fiber-producing methods. Electrospinning facilitates the formation of continuous polymer fibers, derived from polymer melts or solutions, with diameters spanning from the nano to micro scales. The versatility of this method applies to both natural and synthetic polymers, as well as blends, composites containing metals or ceramics, and nanocomposites. The process also results in enhanced surface areas, broadening the scope for innovative material design and uses in diverse areas, such as the creation of filtration systems, catalytic nanofibers, and fiber-based sensors (Yang et al., 2018).

10.2.1 Principles of electrospinning

The primary elements involved in electrospinning consist of a high-voltage electrical source, a flow control mechanism, a spinneret (made up of a syringe pump and needle), and a grounded gathering device, as depicted in Fig. 10.1. During the electrospinning process, the regulated flow of either a polymer solution or melt is released from the spinneret via the syringe

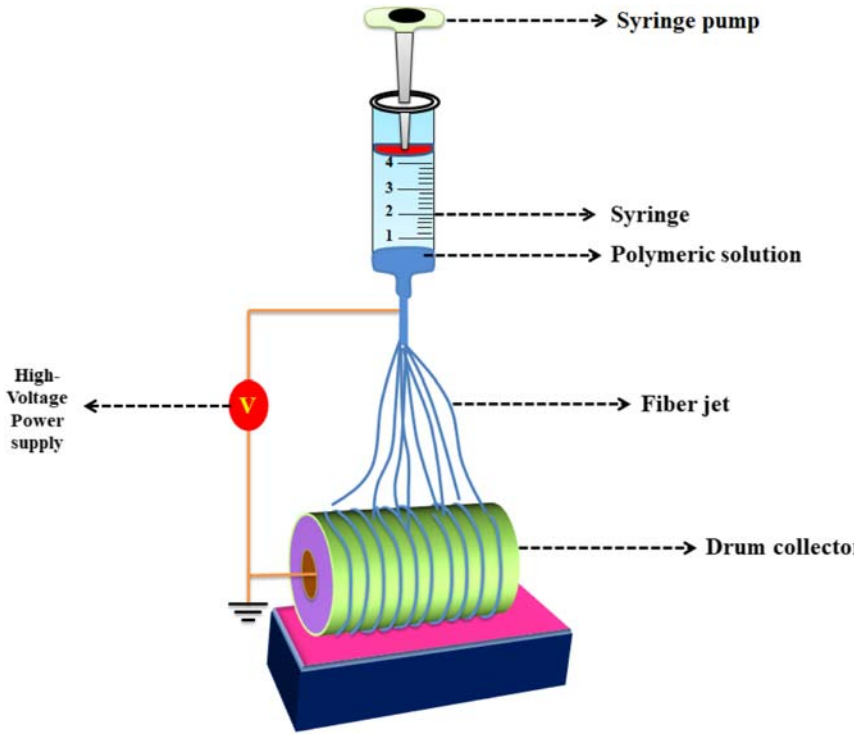

Figure 10.1 Schematic representation of electrospinning equipment.

pump. Initially, due to the effects of surface tension, the released substance appears as hanging spherical droplets. When the high-voltage source is turned on, a significant electric charge forms between the spinneret's tip and the grounded gathering device. This increased voltage results in repulsive electrostatic forces that cause the droplet at the end of the needle to stretch, assuming a cone shape, often referred to as the Taylor cone. When the voltage exceeds a certain limit, the electric field surpasses the droplet's surface tension, causing a thread to extend from the top of the cone. Consequently, one or multiple streams of charged polymer solution emerge. During this jet formation, various aspects affect the process, such as evaporation of the solvent in solution-based electrospinning or solidification of the polymer during melt electrospinning. The electric field's impact on the charged stream also induces it to stretch and waver unevenly. As the process continues, the charged stream quickly becomes more refined and solidified. Eventually, these solidified strands move toward and are captured by a gathering device with the opposite electric charge. This systematic procedure allows for the creation of polymer strands that vary in size from nano to submicron levels (Khan et al., 2013).

10.2.2 Effects of different electrospinning parameters

The investigation into the electrospinning process parameters holds significant importance. By comprehending these variables, it becomes feasible to produce nanofibers with diverse morphologies and diameters, as well as to fine-tune experimental configurations to achieve a variety of fibrous structures and patterns.

10.2.2.1 Solution parameters

Polymer solution properties are largely determined by the molecular weight of the polymer chains. These properties include viscosity, surface tension, conductivity, dielectric strength, and the structure of electrospun fibers (Munir et al., 2009). In general, a greater molecular weight results in improved viscosity, aiding in effective fiber formation. Previous reports explained how molecular weight affects the structural properties of membranes. While maintaining a consistent concentration, clear structural shifts with increasing molecular weight can be achieved. These shifts started with bead-like structures, evolved to beaded fibers, and eventually matured into fully formed fibers and flat ribbons. Nonetheless, a higher molecular weight is not always beneficial for achieving a specific fiber diameter due to the complex interactions among the polymer molecules. In electrospinning,

viscosity and polymer concentration jointly influence the size and shape of the produced fibers. Low viscosity can prevent the formation of continuous fibers, resulting in droplets, whereas high viscosity can cause the polymer solution to dry too quickly at the needle tip. The ideal viscosity varies among polymer types and polymer–solvent combinations (Huan et al., 2015). Polymer solution concentration is a crucial factor affecting fiber morphology. Numerous studies on different synthetic and natural polymer–solvent combinations have found that reduced polymer concentrations lead to an interrupted jet, causing bead formation on the fibers. On the other hand, too much solvent can produce tacky, wet fibers. Higher concentrations might enlarge the fiber diameter or block the jet due to increased polymer surface tension. The relationship among viscosity, surface tension, and the solution's rheology is closely connected to concentration, highlighting the need for the right concentration to obtain consistent fibers. For naturally occurring polymers with an ionic nature, concentration directly affects fiber spinnability and structure. Regarding inorganic solvent concentration, early studies have primarily focused on the chitosan biopolymer because of its solubility in slightly acidic water solutions, which also influences the conductivity of the polymer solution (Gradinaru et al., 2022). Numerous investigations focusing on polymer–solvent interactions have demonstrated that enhancing solution conductivity contributes to the creation of uniform fibers. The introduction of inorganic salts (such as NaCl, $CaCl_2$, $FeCl_3$) has been proven to elevate solution conductivity, even when these salts are incorporated at very low concentrations, leading to the removal of beads within the fibers (Su et al., 2011). The type of salt significantly impacts this conductivity improvement. Salts with smaller ionic diameters exhibit higher charge density and greater ion mobility under an electric field. Consequently, this results in increased elongation force and the production of finer fibers.

The role of the solvent or combination of solvents is vital in determining the conductivity of a solution, as discussed earlier. Using methylene chloride as a solvent for electrospinning PCL solutions, the resultant fibers had a consistent diameter close to 5500 nm, even though this was not the best method. However, when methylene chloride was mixed with DMF, the electrospinning process became more efficient, leading to a notable reduction in fiber diameter as the DMF ratio increased. This was believed to be due to the enhanced dielectric constant and conductivity of the mixed solution (Patlolla et al., 2010). In addition to adding inorganic salts, integrating biomolecules or surfactants can be beneficial. For example, as the

concentration of DNA in DNA/PEO solutions increased, there was a marked increase in their ionic conductivity. Remarkably, solutions with both DNA and PEO showed promising characteristics for electrospinning, producing very fine fibrous mats with diameters between 50 and 250 nm (Liu et al., 2007). Surface tension is majorly determined by the properties of the solvent rather than the polymer itself. The way a polymer solution demonstrates surface tension can vary based on how the polymer interacts with the solvent and the solvent's quantity present. By adjusting the concentration of the solution, either by adding more solvent or mixing solvents, one can prevent the formation of droplets and challenges in forming Taylor's cone. Reducing surface tension also enables the use of a milder electric field. However, adding more solvent changes the solution's thickness, which could lead to uneven fibers with droplets on them (Avossa et al., 2022).

10.2.2.2 Processing parameters

The relationship between the flow rate of a polymer solution and the electric field it experiences is tightly interconnected, with this correlation being particularly distinct based on the specific polymer—solvent pairing. Amplifying the rate at which the polymer solution is delivered leads to the alteration of Taylor's cone, concluding in the development of bead formations. However, this bead formation can be prevented by elevating the applied voltage. Nevertheless, this solution comes with an adjustment: avoiding bead formation through heightened voltage gives rise to uneven diameters and dispersion of the primary fiber. Furthermore, increased voltage accentuates the electrostatic forces within the charged solution, hindering the complete evaporation of the solvent. Conversely, a slower feed rate presents issues, including the inability to eject a polymer solution jet from the needle's end due to rapid droplet evaporation. It is crucial to keep an exact gap between the needle end and the collector to allow adequate drying time for the fibers before they touch the collector. Too short or too long gaps lead to uneven fiber structures. The ideal gap is determined by elements like the polymer solution's density and the voltage used. Essentially, while the electric field determines the fiber's thickness, its importance varies depending on factors like the polymer solution density and the gap between the needle and the collector (Tan et al., 2005).

The magnitude of the electric field not only dictates the size and structure of the fibers but also shapes their biological behavior, including the effect of the field's polarity (Ura and Stachewicz, 2022). The voltage

polarity can alter the performance of fibrous nanocomposite scaffolds in biological settings. It is confirmed that scaffolds with both positive and negative polarities promoted cell expansion and triggered the emergence of filopodia. Notably, scaffolds with negative polarity showed a boost in cell growth, ALP activity, and mineralization in contrast to those with a positive polarity. The design and organization of the collector play a pivotal role in dictating the morphology of electrospun fibers. Diverse collector types have been employed to achieve this, including materials like aluminum foil, conductive paper, and wire mesh, as well as configurations like pins, parallel bars, rotating rods, and rotating cylinders. Additionally, nonsolvents like methanol and ammonium hydroxide have also found utility in this context. In the field of tissue engineering, the most sought-after fiber arrangement mimics the consistent and oriented structure found in collagen fibers within the extracellular matrix. To realize this parallel alignment of fibers, collectors such as parallel bars or a rotating cylinder, have been effectively utilized. It is worth noting that in the case of a rotating cylinder, precise control over the rotation speed is imperative to achieve the intended alignment outcome (Vellayappan et al., 2016).

10.2.2.3 Environmental parameters

Apart from the innate qualities of materials and specific operational parameters, external elements like temperature and ambient moisture play a pivotal role in determining the outcome of the electrospinning method and the characteristics of the nanofibers produced (Phutane et al., 2023). The electrospinning process is significantly impacted by ambient moisture levels. Extremely low moisture conditions can lead to swift solvent evaporation, posing a risk of needle blockage. On the other hand, very high moisture conditions can interrupt the polymer stream, leading to electrospraying. Furthermore, the level of ambient moisture can alter the fiber's structure, a feature that is linked to whether the polymer attracts or repels water. For water-soluble and water-attracting polymers, tweaking moisture levels can help modify the fiber's thickness. When the air is more humid and the temperature drops, the drying speed of the solvent decreases. This extends the journey of the jet, resulting in finer fiber widths. On the other hand, when the humidity decreases, the drying process accelerates, producing coarser fibers. Moreover, elevated humidity can obstruct the drying of the water-based solvent, leading to the creation of bead-like structures. Solvent evaporation speeds up in hotter environments. Additionally, the ambient temperature can affect various properties of the polymer solution or melt,

such as its viscosity, surface tension, and conductivity (Wongsasulak et al., 2007). Furthermore, temperature is also crucial in determining the structure of nanofibers, influencing the solvent evaporation speed and viscosity, which lead to the formation of thinner fibers at both extremely low and high temperatures relative to moderate ones. At cooler temperatures, slower solvent evaporation caused the fiber jet to stretch more. On the other hand, hotter environments lowered the viscosity, enabling the creation of thinner nanofibers. It is worth noting that these effects are specific to the material in question, meaning different polymers might behave differently. Multiple research efforts have highlighted the indirect role of temperature on the diameter and structure of fibers. This suggests a possible use of the interplay between temperature and viscosity in tailoring nanofibers. Meanwhile, for hydrophobic polymers, increased humidity can lead to the formation of porous nanofibers. This is attributed to the complex interactions between water, the polymer's moisture-attracting solvent, and the polymer itself (Mailley et al., 2021).

10.2.3 Improvement and development of electrospinning technology in recent years

Producing laboratory-scale tools for needle electrospinning efficiently is a challenge, making it unsuitable for expansive industrial applications. In recent times, there has been a surge in efforts by scientists to improve the output of the electrospinning process. Various design approaches, adapting both individual and multiple needle setups, have been explored. An example includes using a single nozzle with a ridged end to produce multiple jets, as opposed to the traditional single needle, with the goal of boosting production speed. However, these innovations have not achieved the desired outcomes. The modification using a singular needle did not substantially enhance the output, and the design with several needles encountered issues such as electrostatic clashes among the needles and obstructions (Tan et al., 2022).

Innovatively, needle-free technology has emerged as a promising solution. This approach uses alternative spinnerets instead of traditional needles, tackling issues related to electrostatic disruptions and obstructions. The primary categories of spinnerets in needle-free electrospinning are rotating and stationary spinnerets (Schulte-Werning et al., 2021). Rotating spinnerets bring about mechanical disruption to the polymer mixture, whereas fixed spinnerets use methods like magnetism or bubbles to start the process. Various iterations of autonomous, multi-nozzle needle-free

electrospinning have shown great potential in enhancing the productivity of nanofiber membrane materials. Since 2004, the emergence of alternating current (AC) electrospinning technology has showcased its superiority over the traditional direct current (DC) electrospinning technique. AC electrospinning claims improved efficiency, making it possible to produce multiple jets on droplet surfaces at the same time (Balogh et al., 2015). When compared under the same experimental parameters, AC electrospinning yields results that are more than 20-fold higher than for its DC counterpart. The jets formed through AC methods are more stable during elongation, and due to the utilization of high AC voltage, they carry a reduced charge. This means there is no need for grounding conductive collectors. The natural propensity of the fiber stream to group together makes the creation of consistent nanofiber threads simpler. Furthermore, AC electrospinning offers enhanced precision; the electric or corona breeze surrounding the metal electrode plays a role in the fiber streams stretching. By tweaking the AC voltage and frequency, one can effectively dictate the nanofiber's shape and properties. However, AC electrospinning does have its limitations, which lead to relatively thicker fiber diameters (ranging from 300 to 500 nm) when compared to the ultra-fine 1 nm that can be achieved through DC electrospinning. It is worth noting that recent focus has been on nanofibrous yarn materials created through the AC electrospinning process, especially in the biomedicine sector. These materials consist of interconnected bundles of extremely fine nanofibers, creating structurally strong substances that find utility in diverse biomedical applications. The continuous progress of AC electrospinning technology unquestionably possesses the potential to attract substantial attention in times ahead (Sivan et al., 2022).

10.3 Application of electrospun nanofiber membranes in medical protective equipment

The worldwide outbreak of COVID-19 has led to a deficit in vital medical protection equipment, placing the health of medical professionals at risk. This challenge emphasizes the importance of innovative and accessible solutions that offer both antimicrobial and antiviral defenses. An emerging approach involves using electrospun nanofiber layers to produce medical items like masks and protective wear (Wu et al., 2022). These layers are preferred due to their high surface porosity, chemically modified surfaces that boost filtration capabilities, and their lightweight, breathable

characteristics. Lately, there has been a significant increase in research focused on leveraging electrospun nanofiber layers for healthcare protective purposes. In this field, a notable advancement is the development of a multifunctional composite made from electrospun nanofibers which includes polymethyl methacrylate (PMMA), ZnO nanorods, and silver (Ag) particles, termed PMMA/ZnO−Ag particles. This mixture serves as a decorative element for crafting protective padding. It has properties that can resist bacteria and viruses, helps in breaking down organic pollutants via photocatalysis, and can be reused (Ivanoska-Dacikj et al., 2023). Inspired by the above a biodegradable multi-layered mask with a filtration section formed from nanofibers of polylactic acid was proposed (Patil et al., 2021). These fibers were produced without the use of needles in the electrospinning process and proved potent against pandemics. Also, a unique Janus fiber membrane based mask, which provides holistic protection, tackling both airborne particulates and allowing for one-way water transfer, has been prepared. Another study demonstrated the feasibility of designing a superhydrophobic microporous layer through electrospinning, which is both water-resistant and breathable, and ideal for protective uses. Together, these examples highlight the critical significance of electrospun nanofiber membranes in various sectors for promoting health and safety.

10.3.1 Medical device and implant coating

The potential integration of electrospun nanofibers into medical implants offers considerable potential, aiming to improve biocompatibility and introduce innovative features. This strategy involves producing a nanofiber-based layer on the implant's surface, imparting unique surface qualities that enable interaction with neighboring cells and tissues. Through the incorporation of bioactive compounds or even cells within these nanofibers, the creation of adaptable coatings for medical devices, including advanced controlled drug-delivery systems, becomes feasible. For instance, application of this technique in depositing a porous PCL layer onto biodegradable magnesium prostheses using electrospinning was demonstrated. This porous coating not only facilitated better cell adhesion but also provided a platform for the controlled release of medications, particularly aimed at addressing infections (Matsuzaki et al., 2020). Another illustration pertains to Biotronik's PK Papyrus coronary stent system, which integrates a polyurethane coating to enhance its flexibility. Furthermore, in the field of aneurysm treatment, a stent was enveloped in

nanofibers comprising of poly(L-lactide-co-ε-caprolactone) (PLCL) to promote anticoagulation and swift growth of endothelial cells. This distinctive coating exhibited a central-core and outer-sheath arrangement, allowing a gradual discharge of enclosed compounds such as heparin and vascular endothelial growth factors over an extended period, avoiding any immediate rapid emission. Integrating nanofibrous coatings functions as an intermediate layer situated between implants and host tissues, effectively tackling the important issue of stiffness mismatch at the junction. This problem is particularly noteworthy when considering the potential risks associated with the malfunction of rigid tissue prostheses (Naseem et al., 2019).

10.3.2 In-vitro 3D cancer models

In the field of cancer research, in vitro models have proven to be a valuable asset for a range of purposes, including drug screening, understanding anticancer mechanisms, and exploring tumor cell biology. Traditional two-dimensional (2D) cancer models involve growing tumor cells as a single layer in flat containers, which provides some insights into cancer cell behavior. However, it is important to acknowledge that the behavior of tumor cells varies significantly between 2D and 3D models. The limitations of 2D models become apparent in their inability to replicate the intricate interactions between cells and their surrounding matrix, both on a cellular level and within the matrix itself. This is precisely where three-dimensional (3D) models come into play, offering a more comprehensive perspective on how cells collectively behave within the complex cell—matrix environment. This enhanced understanding enables a more effective control of tumor activities. Electrospun nanofibers possess a remarkable capacity to mimic the natural structure and composition of the extracellular matrix (ECM). This is a crucial factor for tissue regeneration and replicating stem cell environments. Similarly, in the realm of creating three-dimensional in vitro tumor models, the employment of electrospun nanofibers plays a pivotal role in accurately recreating the genuine extracellular environment for tumor cells. By incorporating biochemical signals through surface modifications involving biomolecules or enclosed medications, electrospun nanofibers effectively mirror the cues found in the native tumor ECM (Yang et al., 2015). This combination has led to the development of a pharmacokinetic model for prostate cancer.

Nonetheless, it is imperative to acknowledge the intricate and varied physiological composition of the tumor's ECM. The current predicament

introduces challenges regarding the fabrication of electrospun 3D tumor models, as they face limitations in faithfully reproducing essential components like tumor angiogenesis, intercellular communication, mechanical impacts, and efficient cell penetration (Monteiro et al., 2019). The integration of bioreactors into the model development process is being investigated as a promising approach to mechanically stimulate cancer cells. Furthermore, a more advanced tactic encompasses the fusion of electrospinning with bioprinting technology, holding the potential to craft more intricate 3D cancer models.

10.3.3 Filtration membranes for biomedical applications and wearables

The exceptional qualities of electrospun nanofiber networks include their remarkable surface-to-volume ratio, lightweight composition, significant porosity, interconnected structure, and microscale gaps. These attributes make them an ideal option for filtration applications, particularly in personal protective equipment. Unlike traditional protective clothing that prioritizes creating a complete barrier, but struggles with being heavy and retaining moisture, electrospun nanofibers offer the potential to develop textiles that are both incredibly lightweight and breathable. These textiles allow the passage of air and water vapor while effectively blocking undesirable agents. Biomedical scenarios widely utilize filtration membranes like protective masks. Electrospun nanofibrous membranes provide an opportunity not just to hinder, but also potentially to neutralize chemical and biological hazards such as nerve agents, bacteria, and viruses by integrating active substances into the nanofiber structure. For instance, the infusion of silver nanoparticles into electrospun nonwoven PAN nanofibrous matrices resulted in a 99% bacterial filtration efficiency, alongside notable antibacterial characteristics (Selvam and Nallathambi, 2015).

During the COVID-19 pandemic, the need for face masks grew significantly, leading to shortages in supply. In response, researchers at the Korea Advanced Institute of Science and Technology (KAIST) developed reusable masks using nanofiber filters that could be washed and utilized again. These masks incorporate nanofibers arranged in a crisscross pattern, ranging in dimensions from 100 to 500 nm. After conducting 20 rounds of tests to assess their antibacterial properties using ethanol, these masks exhibited an impressive filtration efficiency of over 94%. They maintained their hydrophobic features and retained their shape despite repeated usage. Additionally, Inovenso Ltd. contributed to the cause by manufacturing

masks with nanofibers, employing multiple layers of nonwoven electrospun material. These particular masks showcased an outstanding filtration efficiency of 99.9%. Nanofiber masks possess unique characteristics such as small pore size, large surface area, and lightweight nature, positioning them as a promising advancement in the realm of protective face masks. This innovation holds promise in meeting the demand for effective and reusable protection against viral particles and other contaminants (Persano et al., 2013).

10.4 Conclusion

The technique of electrospinning presents considerable benefits, foremost among which is the production of ultra-thin fibers with extensive surface areas. This approach also enables tailoring for various purposes, showcases impressive mechanical properties, and is characterized by its straightforward procedural elements. These advantages collectively open up a wide array of possibilities for implementation in the biomedicine sector. The applications of this technique span diverse fields, including tissue engineering, controlled drug release, implantology, biotransformation, and wound healing. By adjusting the electrospinning process, material properties can be seamlessly integrated with distinct morphological structures, effectively meeting the requirements of these diverse applications. Despite the growing body of literature in this domain, it is important to acknowledge that the use of electrospinning for biomedical purposes is still in its nascent stages of advancement. The capability for nanoscale surface modifications and the versatility in material selection for electrospinning empower researchers to create innovative scaffold designs. These innovations have led to breakthroughs in areas such as bone and cartilage regeneration, vascular grafts, artificial heart valves, and artificial myocardial tissue. Noteworthy is the clear advantage of the fine diameters and adjustable pore sizes found in electrospun nanofiber films, particularly in crafting wound dressings and medical protective equipment. Biological evaluation studies highlight that the electrospinning process conditions do not compromise the effectiveness of integrated growth factors and other functional biomolecules, including anticancer agents, proteins, DNA, and living cells. Unquestionably, electrospun materials are poised to play a pivotal role in the future of biomedical applications. However, it is crucial to develop methods and materials that can be scaled up to meet the technical demands of these applications.

11.1 Introduction

The emergence of innovative controlled drug-delivery methods, such as nano-drug-delivery systems (NDDSs), has significantly improved drug delivery. Polymers perform a vital role in manipulative controlled-release drug-delivery system (CRDDS) and sustained-release drug-delivery system (SRDDS). Since the invention of biodegradable (bioresorbable) polymers, a fantastic improvement in drug-delivery applications has taken place (Prajapati et al., 2019). Biodegradable polymers originating from synthetic and natural sources have been developed and applied for the design of controlled, sustained, and delayed-release drug-delivery carriers. The use of biodegradable polymers in drug delivery and drug targeting is extremely challenging due to problems with compatibility between biological tissue and biodegradable polymers as well as the release kinetics of biodegradable nanoparticles (Jacob et al., 2022). Following water absorption and swelling, the drug release primarily depends on whether polymer depletion controls it or occurs during migration. It has been claimed that the polymer's capacity for medication delivery has changed (Trucillo, 2022).

11.2 Biodegradable/bioresorbable polymers

Biodegradable/bioresorbable polymers showed a significant role in the improvement of pharmacokinetics as well as in reducing the side effects of active pharmaceutical ingredients (APIs) as they developed harmless or biocompatible products after degradation either enzymatically or non-enzymatically inside the body (Gavasane and Pawar, 2014). Recent advancements in tissue engineering, regenerative medicine, vaccination, CRDDS, SRDDS, nucleic acid, protein, and anticancer drug delivery have focused on the application of biodegradable biomaterials/polymers (George et al., 2019). As their name indicates, after the biodegradation of these polymers, the resulting product is not harmful either to the body or the environment after excretion. To date, researchers have reported and employed a number of biodegradable polymers with either natural or synthetic origins (Rancan et al., 2014). Natural biodegradable polymers involve polysaccharides of non-human origin such as chitosan and its derivatives including glycol chitosan, hyaluronic acid, sodium alginate, etc., and protein and polypeptide-based ones like collagen, albumin, gelatin, elastin, etc. (Prajapati et al., 2019; George et al., 2019; Idrees et al., 2020) (Fig. 11.1).

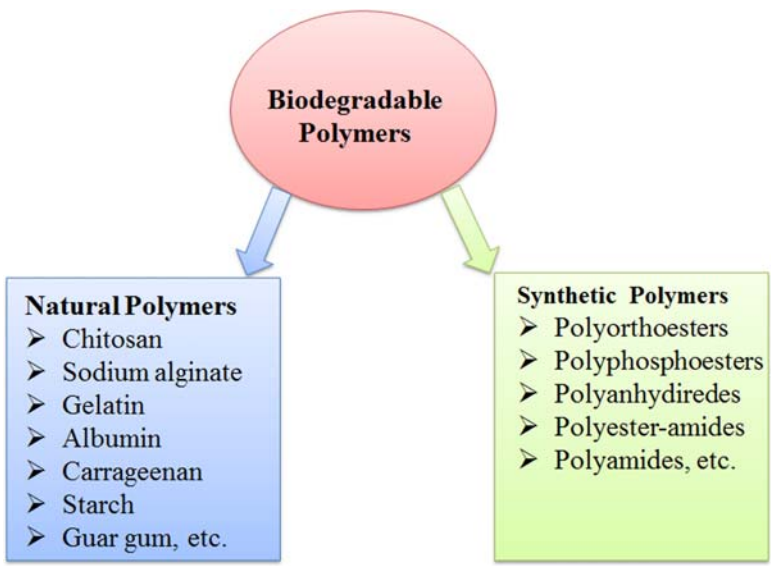

Figure 11.1 General classifications of biodegradable polymers used for the preparation of CRDDS.

Synthetic polymers involve poly(α-esters) such as poly(glycolic acid) (PGA), poly(lactic acid-co-glycolic acid) (PLGA), polydioxanone (PDS), polyanhydrides, polyurethanes, and poly trimethyl carbonates) (George et al., 2019; Anwar et al., 2021) (Fig. 11.1).

Researchers utilized both natural and synthetic polymers to develop pharmaceutical formulations like *Illicium verum* polymeric nanoparticles were developed using PLGA as biodegradable polymers and the in vitro release pattern was studied. It was concluded that polymeric nanoparticles showed an initial burst release for 1 h and then there was a controlled release for up to 30 h (Kumari et al., 2022). Poly(ester anhydride)s polymeric nanoparticles containing propranolol were developed and the findings suggested that the drug release mechanism for the developed formulation was primarily controlled by surface erosion (Mönkäre et al., 2012). Recently, researchers have used biodegradable polymers for the development of nanoparticles such as PLGA (Shamarekh et al., 2020; Musumeci et al., 2018), thiolated chitosan (Bari et al., 2015), chitosan (Shah et al., 2016; Elnaggar et al., 2015), PEG-PLGA (Pachauri et al., 2015), and carboxy methyl chitosan (Liu et al., 2018).

There are two *vital* factors, namely biodegradation and drug release from a polymeric matrix, that play an imperative role in the fruitful development of nanoformulations. Mechanisms like drug solubility, matrix diffusion, desorption of drug adsorbed, matrix erosion, matrix swelling, and a combination of two or more mechanisms affect the rate at which drugs are released from the polymeric matrix. The drug will be released through erosion or diffusion of the matrix if it is uniformly distributed throughout the matrix system (Begines et al., 2020). When a drug diffuses more quickly than the matrix, the term "burst release" is employed, which is often used to describe a drug that is poorly attached to the surface of polymeric nanoparticles (PNs). In contrast, if the drug is loaded via the incorporation method, the system exhibits a sustained/controlled release pattern (Bruschi, 2015a). The diffusivity and solubility of the drug become the key considerations for drug release if the nanoparticles are coated with a polymer, which acts as a barrier to the release of the drug. If a supplement is added, the way in which the supplement interacts with the drug will impact the rate at which it is released. Various techniques are used to examine a drug's in vitro release, but the dialysis bag diffusion approach, which is carried out with the use of a dissolving apparatus, is the most popular (George et al., 2019).

11.3 Factors affecting drug release from polymers

The prediction of drug release and the drug-release mechanism is an essential step to ensure the goal of the designed CRDDS or SRDDS formulation. Drug release from the drug carrier essentially depends upon the polymer's physicochemical features and physiological medium (Fig. 11.2). The possible detrimental factors for drug release from polymers are; (1) the medium and its pH; (2) the dissolution and diffusion of the drug from the drug carrier; (3) polymer and drug nature, i.e., hydrophilic or hydrophobic; (4) pattern of drug distribution in the polymer; (5) particle size of the drug and the developed system; and (6) the molecular weight of the polymers. Using both hydrophilic and hydrophobic polymer mixtures can avoid burst release and modulate the pattern of the drug's release (Fu and Kao, 2010).

The drug-release features of a polymer can be adjusted by using different viscosity-grade polymers like hydroxyl propyl methyl cellulose (HPMC) or by selecting a desired viscosity polymer (Siepmann and Peppas, 2012). Drug diffusivity from the polymeric system decreases with the molecular weight the polymer and hence retards drug release (Dhaliwal and Dosanjh, 2018). Drug to polymer ratios also play a role in releasing the drug. Hydrophilic polymers promote the burst release phenomena. Additionally, some excipients may be present in the formulation for a variety of reasons. For instance, PVA and mannitol are added to a formulation as a stabilizer and diluent/sweetening agent, respectively. PVA can reduce the

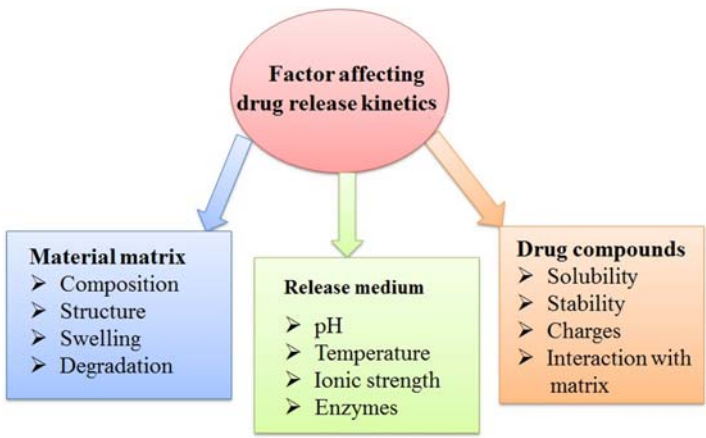

Figure 11.2 Factor affecting drug-release kinetics from a polymeric matrix.

burst release effect, while mannitol can improve the porosity of the matrix and, consequently, the drug-release rate (Joshi and Patel, 2012).

For the development of an effective nanoparticulate system, the biodegradation of the polymer and drug release from the polymer are necessary. The drug's solubility, matrix diffusion, adsorbed drug desorption, matrix erosion, and a combination of two or more mechanisms all have an impact on how a drug is released from a polymer system (Idrees et al., 2020). It is known that the drug will be released via erosion or diffusion mechanism if it is evenly distributed throughout the nanospheres/matrix. The phrase "burst release" is applied if API diffuses quicker than the matrix and is typically applied to weakly bound API on the surface of PNPs (Su and Kang, 2020).

11.4 Diffusion law

Diffusion is the result of intermixing of molecules due to Brownian motion caused by molecular kinetic energy. The unique distribution of dye in water is the simplest example of diffusion. The movement of dye molecules takes place in water until the establishment of equilibrium leads to the development of uniform color in the whole solution. At equilibrium, there is no net movement of dye molecules in the water. A similar phenomenon happens in the body as a drug is distributed, but in this case, equilibrium does not exist due to the establishment of the in vivo sink condition which ensures complete drug absorption from the dissolution site to the systemic circulation. In the case of CRDDS/SRDDS, diffusion is responsible for the passage of drug from the polymer matrix to the in vitro or in vivo medium. This process was explained by Fick (1855) by providing two separate laws. "These laws are useful to determine the flux and drug concentration across the biological membrane."

11.4.1 Fick's first law of diffusion

According to this law, "When the system is at steady state, the flux travels (with a magnitude that is proportional to the concentration gradient) from the area of highest concentration to the area of lowest concentration". Mathematically this law can be stated as follows:

$$J = -D\frac{dC}{dX} \tag{11.1}$$

where D is the diffusivity/diffusion coefficient of the drug, which can be expressed by the units m^2/s or cm^2/s, $\frac{dc}{dx}$ is the concentration gradient, and J is known as flux which indicates the drug amount moving perpendicularly over the unit surface area/time. The unit of J is $kg/m^2/s$ or $g/cm^2/s$. J is not a negative value. A negative sign in Eq. (11.1) indicates a concentration drop with distance, otherwise, flux is not a negative value. If there is no change in concentration (mean uniform concentration) with distance (x)/position, there will be no flux.

The diffusion rate (flux) through the unit area is a time-independent process in steady state. In this term, Fick's first law can be presented as follows:

$$J = \frac{dM}{S.dt} \tag{11.2}$$

After combining both equations, a new Eq. (11.3) will be generated that represents the rate of mass transfer as per Fick's law:

$$\frac{dM}{dt} = -DS\frac{dC}{dX} \tag{11.3}$$

D generally does not remain constant. Factors like concentration, temperature, pressure, solvent characteristics, and the chemical makeup of the drug all have an impact on D.

11.4.2 Fick's second law of diffusion

This is applicable under an unsteady state condition and represents how the concentration of diffusant alters with time. It states that "the concentration of diffusant alters with time ($\Delta C/\Delta t$) as the flux or diffusant amount alters with distance ($\Delta J/\Delta x$) in the x direction."

$$\frac{\Delta C}{\Delta t} = -\frac{\Delta J}{\Delta X} \tag{11.4}$$

Eq. (11.4) indicates the first form of Fick's second law. Another form can be differentiated as per Eq. (11.5).

$$\frac{dC}{dt} = -\frac{dJ}{dX} \tag{11.5}$$

By incorporating $J\left\{J=-D\frac{dC}{dX}\right\}$ value from Fick's first law, another form of Fick's second law can be obtained as follows:

$$\frac{dC}{dt}=-\frac{d}{dX}\left[=-D\frac{dC}{dX}\right] \tag{11.6}$$

It is assumed that D is constant and independent of X. It can be taken out from the differential:

$$-\frac{dJ}{dX}=D\frac{d^2C}{dX^2} \tag{11.7}$$

$$-\frac{dC}{dt}=D\frac{d^2C}{dX^2} \tag{11.8}$$

This is the third form of Fick's second law (Eq. 11.8). It states that any variable if its differential coefficient concerning time is related to second differential coefficient concerning space through a constant like D is known as a diffusion equation.

11.4.2.1 Outcomes of Fick's second law

- According to Fick's second law, the gradient of the concentration change at a given region in the system is proportional to the change in concentration over time in that region.
- This law is useable when the initial amount of drug per unit volume is lesser than the dimensional solubility of a drug.
- It narrates the temporal and spatial distributions of a drug concentration.

11.5 Fundamentals of drug-release kinetics

Drug-release patterns from the delivery system play an important role in the maintenance of the desired drug concentration at the receptor site/blood (Dash et al., 2010).

Noyes and Whitney conducted a dissolution experiment on two sparingly soluble compounds, namely benzoic acid and lead chloride (Noyes and Whitney, 1897). During the performance of experiment, both temperature and stirring speed were kept constant (Dokoumetzidis and Macheras, 2006). The experiment concluded that the dissolution rate was proportional to the concentration gradient, i.e., the difference between the

instantaneous concentration (C) at time t, and the saturation solubility (Cs) and modulated in the mathematical term as

$$\frac{dC}{dt} = k\,(Cs - C) \tag{11.9}$$

where k was considered a constant. The authors concluded that during drug dissolution, a thin layer was developed around the solid drug surface. The movement/diffusion of the drug was taken place from the solid surface to this layer to saturate it, followed by from this layer to the bulk of the solvent/solution (Dokoumetzidis and Macheras, 2006).

In 1900, Erich Brunner and Stanislaus von Tolloczko incorporated the surface area in the equation given by Noyes and Whitney and proposed the following equation (Bruner and Tolloczko, 1900):

$$\frac{dC}{dt} = k_1 S\,(Cs - C) \tag{11.10}$$

where $k = k_1 S$. They postulated that the exposed surface area of the drug to the dissolution medium, surface structure, and apparatus configuration all had an impact on the dissolution rate.

Brunner (1904) and Nernst (1904) modified Eq. (11.10) by utilizing the diffusion layer concept and Fick's second law and provided the following equation:

$$\frac{dC}{dt} = \frac{DS}{Vh}(Cs - C) \tag{11.11}$$

Here, D denotes the diffusion coefficient, h denotes the thickness of the diffusion layer, and V denotes the volume of dissolution medium (Gouda et al., 2017). According to Eq. (11.11), dissolution followed the first-order kinetic rate. Here, the concentration gradient i.e., $(Cs - C)$, acts as a driving force for drug dissolution. There is a chance to establish equilibrium, especially under nonsink/poor-sink condition in the case of in vitro dissolution. Due to the continuous circulation of blood in vivo, there is a better chance of the establishment of sink condition as compared to in vitro, and C is always approaching zero. If all other parameters keep constant, Eq. (11.11) reduces as $dC/dt = K$. Here, K is considered an overall constant that contains all the constants of Eq. (11.11). In this case, dissolution followed the zero-order kinetics.

In 1931, Hixson and Crowell modified Eq. (11.11) by utilizing the surface area (S) in terms of weight (w) (Hixson and Crowell, 1931).

They considered the surface area to be proportional to $w^{2/3}$. The generated equation after integration was applicable for the dissolution of compact material.

$$w_0^{1/3} - w^{1/3} = k_2 t \tag{11.12}$$

Here, w^0 is the initial weight, and k_2 is considered a constant. As a physical explanation for the process of dissolution, the aforementioned methods can be categorized as various expressions of the diffusion layer concept. The diffusion of molecules through a stationary film of liquid around the solid surface has been proposed as the limiting step. An interfacial barrier model for dissolution was proposed by Wilderman (1909), who was followed by Zdanovskii (1946), by taking interfacial transport into account rather than diffusion through the film. A third model of dissolution, the Danckwerts model, was presented by Danckwerts in 1951. This model states that constantly renewed macroscopic solvent packets reach the solid surface and absorb molecules of a solute, delivering them to the solution (Dokoumetzidis and Macheras, 2006).

11.6 Need for and objectives of mathematical models

New DDS can be designed by choosing the best size, formulation approaches, and geometry, and using the mathematical model equation. By choosing the best size, formulation approaches, and geometry, one can optimize new systems using the mathematical model equation. By fitting an appropriate model, the mathematical modeling approach assists in forecasting the drug-release rates and diffusion behavior from developed drug carriers, hence reducing the number of trials needed to optimize the DDS. The mathematical simulation of CDD can help scientists better understand the mass transport systems involved in the regulation of drug release (Ramteke et al., 2014; Siepmann and Siepmann, 2013). Therefore, mathematical modeling can greatly aid in the development of novel pharmaceutical goods as well as the optimization of already existing ones. Models can be used systematically to save time and money. Researchers may be able to create more precise dosing regimens and more effective therapeutic compositions with the use of mathematical methodologies (Costa and Sousa Lobo, 2001). Several mathematical model equations are described in the literature as described below (Trucillo, 2022; Dash et al., 2010; Costa and Sousa Lobo, 2001; Bhansali, 2021; Bruschi, 2015b; Elmas et al., 2020).

11.7 Release kinetic modeling

To describes the general drug release from dosage forms, different kinetic models have been devised. Because qualitative and quantitative changes in a formulation may alter drug release and in vivo performance, it is typically preferred to develop approaches that facilitate product development by reducing the requirement for biostudies. In this way, the rational development of CRDDS could be viewed as the use of in vitro drug dissolution data to predict in vivo bio-performance (Dash et al., 2010; Shaikh et al., 2015). As illustrated in Fig. 11.3, three different approaches can be utilized to assess the kinetics of drug release from CRDDS:

- Statistical approach
- Model-dependent approach
- Model-independent approach

11.7.1 Statistical approach

11.7.1.1 Explanatory data analysis approach

Although exploratory data analysis methods are not currently endorsed by the FDA, the method is useful in obtaining an improved understanding of the dissolution data of controlled release formulation, and therefore, its use is recommended (Dash et al., 2010; OíHara et al., 1998). This method can be used in the first step to compare dissolution profile data in both graphical and numerical manner.

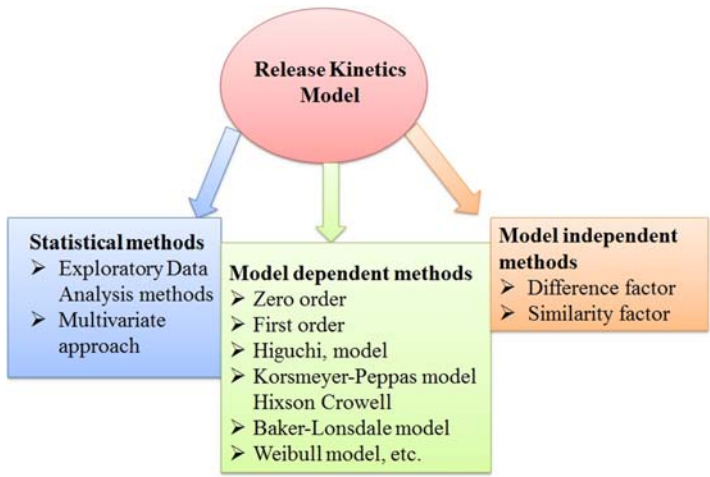

Figure 11.3 Classification of drug-release kinetic models.

11.7.1.2 Multivariate approach

Its foundation is based on the concept of repeated measure design. Here drug dissolution (%) is a dependent factor, while time is a repeating component. It is the standard method for determining whether a set of response measurements differs among the various population groups. Specifically, MANOVA examines both the statistical significance of the overall effect as well as the statistical significance of a specific main effect or an interaction on each of the response measurements. The level of connection between the group of dependent variables taken into account in a given study can also be determined using MANOVA (Liu, 2016).

11.7.2 Model-dependent approach

Designing controlled-release dosage forms requires the use of mathematical models for release kinetics (Gao, 2011). Mathematical models can be used to theoretically estimate the proportions of the drug, polymer, and other excipients as well as the optimal system size and shape to achieve the desired release profile in addition to assisting assessment of the physical aspects like the diffusion coefficient (Bhansali, 2021). The dissolution profile is described by many mathematical functions that form the foundation of model-dependent approaches. Once a suitable function has been chosen, the generated model parameters are used to evaluate the dissolution profiles. The model-dependent approach includes the various kinetic model, as listed in Fig. 11.3 and Table 11.1 (summary of various model-dependent approaches). Each model offers a unique equation that can convert the data from the release profile into a function that allows quantitative interpretation of the dissolution data.

11.7.2.1 Zero-order model

Eq. (11.13), which uses zero-order kinetics to describe the release rate of the nondisintegrating system, shows that the release rate is independent of the initial concentration or amount.

$$Q_t = Q_0 - KT \tag{11.13}$$

Here, Q_0 denotes the initial drug concentration, Q_t is the concentration of drug released from the system at time t, and K denotes the zero-order release constant (concentration * time^{-1}). In this instance, a graph of time (X-axis) and cumulative drug release (CDR, %) (Y-axis) results in a straight line whose slope will provide the value of the release constant,

Table 11.1 Summary of different kinetic release models.

Model	Mathematical relation	Plotting parameters	Assumptions	Application	References
Zero-order	$Q_t = Q_0 - Kt$	Time versus CDR (%)	Drug release form delivery system is independent of initial concentration (constant release).	Followed diffusion mechanism, Used for transdermal matrix system, Coated tablet with low water-soluble API, etc.	AlMajed et al. (2022)
First-order	$\text{Log } Q_t = \text{Log } Q_0 - Kt/2.303$	Time versus log % drug remained to release	Concentration-dependent, factors like exposed surface area and its structure, Physical factors like temperature, stirring speed, geometry of apparatus, etc. influence dissolution.	Followed diffusion mechanism, Describe drug-release form modified-release DDS containing water-soluble drug in porous medium, etc.	Dash et al. (2010)

Higuchi model	$Q_t = K_H\sqrt{t}$	Square root of time versus CDR (%)	Pseudo-steady-state condition for planar system, Volume change should be negligible, Establishment of sink condition, Smaller drug molecules with respect to DS thickness.	Followed diffusion mechanism, Solid or semi-solid DDS containing soluble API, Planar, variable geometrics, and porous DDS, Matrix DS with soluble polymer, etc.	Bhansali (2021)
Hixson –Crowell cube root law	$w_0^{\frac{1}{3}} - w^{\frac{1}{3}} = k_2 t$	Time versus $w_0^{\frac{1}{3}} - w^{\frac{1}{3}}$	Drug release is limited by dissolution of drug particle rather diffusion.	Erodible matrix DDS, Valid for DDS with diminished SA and thickness, Maintenance of constant initial geometry, etc.	Shaikh et al. (2015)
Korsmeyer –Peppas	$\frac{M_t}{M_\infty} = Kt^n$	Log time versus log M_t/M_∞	DDS with different geometries, DDS where	Semiempirical approach, Based on exponent value,	Ramteke et al. (2014)

Table 11.1 Summary of different kinetic release models.—cont'd

Model	Mathematical relation	Plotting parameters	Assumptions	Application	References
			one-dimensional diffusion cannot be assumed.	It differentiates release in Fickian and non-Fickian diffusion, Applied for wide dosage forms like hydrogels, etc.	
Weibull distribution	$m = 1 - e\left[-(t - T_i)^{\frac{b}{a}}\right]$	Log time versus log CDR (%)	Empirical approach	Empirical approach, May be applied for majority of DDS with more emphasis on matrix DDS.	Bruschi (2015b)
Hopfenburg model	$\frac{M_t}{M_\infty} = 1 - \left[1 - \frac{K_0 t}{C_0 a_0}\right]^n$	Time versus log M_t/M_∞	Drug release from erodible DDS that maintains constant SA during degradation.	Semiempirical approach, Erosion mechanism, Applied for oily spheres dispersed in biphasic DDS, etc.	Siepmann and Siepmann (2008)

Baker −Lonsdale model	$f_1 = \frac{3}{2}\left[1-\left(1-\frac{M_t}{M_\infty}\right)^{2/3}\right]-\frac{M_t}{M_\infty} = KT$	Root of time inverse versus $d\left(\frac{M_t}{M_\infty}\right)\Big/dt$	Drug release from spherical matrix, Negligible drug release initially.	Drug release from homogeneous nonfractured spherical matrices like microspheres, microcapsules, etc.	Trucillo (2022)
Peppas −Sahlin model	$\frac{M_t}{M_\infty} = K_1 t^m + K_2 t^{2m}$	Time versus log M_t/M_∞	Fickian diffusional and relaxational contribution.	Swellable polymeric devices	Shaikh et al. (2015)
Gompertz model	$M_t = M_{\max}\exp\left(-\alpha\, e^{\beta \log t}\right)$	Time versus $M_t/M_{\max}$	–	Compares the release profile of API with good solubility and intermediate release rate, etc.	Dash et al. (2010)

which is a function of time and is utterly independent of initial drug concentration (Bhansali, 2021).

The zero-order release approach can be applied to oral delivery when the drug core is covered by a water-permeable barrier. The system is hydrated as soon as it comes into contact with gastrointestinal fluid. The drug then builds a saturated reservoir as water moves toward the core of the object. Following partitioning into the membrane, the drug is then diffused into the GI fluids. The drug-saturated reservoir is responsible for maintaining the drug release regularly and constantly. The release rate decreases until it reaches zero after the drug concentration falls below the saturation concentration (Costa and Sousa Lobo, 2001; Gao, 2011).

Shivanand Puthli and coworkers developed levonorgestrel (LNG)-loaded microspheres using PLGA. The release kinetics of LNG from microspheres was found to be zero-order kinetics with the highest R^2 (Puthli and Vavia, 2009). Mariz et al. developed an ocular insert with PCL-PEG-PCL block copolymers using two different concentrations of PEG (24% and 33%). Both formulations exhibited zero-order release kinetics followed by the super-case-II transport release mechanism as the release exponent value (n) was more than 0.85 (Mariz et al., 2022). As mentioned in the literature, such a type of transport is usually observed in erodible and/or swelling matrixes or osmotically CRDDS (Mariz et al., 2022). Ulya Badilli and coworkers developed etofenamate-loaded topically administered semisolid lipid nanoparticles (SLNs) with an antiinflammatory activity using precirol ATO 5 and other lipids. The formulation developed by precirol ATO 5 displayed zero-order release kinetics. The release mechanism was found to be super-case-II transport release mechanism as the release exponent value (n) was more than 0.85 for all the formulations along with optimized formulation prepared with precirol ATO 5, indicating erosion as a release mechanism (Badilli et al., 2015).

11.7.2.2 First-order model

The release rate of a nondisintegrating system is dependent on the concentration/amount of the drug at a specific point. This model was created by Gibaldi and Feldman (1967) and afterward Wagner (Ramteke et al., 2014). Release kinetics and even drug absorption, distribution, elimination, and many more processes in pharmacy can be described by first-order kinetics as represented by the following equation:

$$\text{Log } Q_t = \text{Log } Q_0 - Kt/2.303 \tag{11.14}$$

In this instance, the plot between time (X-axis) and log of drug remaining to be released generates a straight line with a slope of $-K/2.303$. From the slope, K value can be calculated.

A variety of drug-delivery systems such as a porous matrix with a uniform distribution of drugs utilize the first-order drug-release model. Moreover, the drug release decreases as the drug concentration present in the delivery carriers is depleted (Bhansali, 2021).

A research work was reported by Malihe Pooresmaeil and associates for the preparation of carboxymethyl cellulose/mesoporous magnetic graphene oxide containing poorly water-soluble drug (Ibuprofen/IBU). Their result demonstrated that the first-order release kinetics model was the best-fitted among the all applied models with the non-Fickian release mechanism (Pooresmaeil et al., 2020). Chitosan microspheres containing methotrexate (MTX) were developed by Rajesh R. Dubey. The release kinetic of MTX from the microspheres was found to be collectively following the first-order and Higuchi's release model (Dubey and Parikh, 2004). Another study was conducted by Marilisa G. Lara for the development of cubic phase gels containing salicylic acid using a glyceryl monooleate/water system. The system followed the first-order and Higuchi's release model (Lara et al., 2005). Other researchers have reported different kinetic models to be fitted in various developed formulations such as drug release followed by the square root of time dependence, utilizing GMO/water systems, which is suggestive of a diffusion-regulated release mechanism (Chang and Bodmeier, 1997). Tinnabhop Santadkha developed curcumin nanomicelles using Pluronic F127/oleic acid(OA)-Fe_3O_4. The drug was released by first-order and the mechanism was a Fickian type of diffusion (Santadkha et al., 2022). *Illicium verum* polymeric nanoparticles were developed using PLGA. The drug-release experiment was conducted in PBS pH6.8. The results showed that the drug's swelling and diffusion affect its release (first-order). In this case, the release mechanism was non-Fickian (Case II transport) with a 1.03 value for the release exponent (Kumari et al., 2022).

11.7.2.3 Higuchi's model

The initial mathematical model for drug release from a matrix was presented by Higuchi. His work was associated with planar systems like ointment bases, and was started in 1961 and finalized in 1962. Higuchi eventually put forth the "mechanism of sustained-action medication" in 1963. Higuchi gave the following Eq. (11.15) to represent mathematically the release from the lipophilic planar matrix system:

$$Q = \sqrt{D\,(2C - C_s)C_s t} \tag{11.15}$$

This equation provides the relation between Q = amount of drug release/unit area at the time, C is the initial drug concentration, C_s = solubility of the drug in the matrix, and D = diffusion coefficient. For drug carriers holding a modest dose of the drug, an analogous connection was hypothesized, where release is controlled by the system's porosity as follows:

$$Q = \sqrt{\frac{D\varepsilon}{\tau}(2C - C_s)C_s t} \tag{11.16}$$

Here, ε and τ are the porosity and tortuosity, respectively, of the matrix. A simpler version of both Eqs. (11.15) and (11.16) is given by the following:

$$Q_t = K_H\sqrt{t} \tag{11.17}$$

where K_H is known as Higuchi's release constant. Eq. (11.17) shows a directly proportional relationship between the rate of drug release (water-soluble and poorly water-soluble) from different matrixes and the square root of time (Jain and Jain, 2016; Siepmann and Peppas, 2011). To obtain Higuchi's curve, a graph should be plotted between $\sqrt{t}$ (square root of time, X-axis) and Q_t (%CDR, Y-axis). The slope of the straight line gives the value of Higuchi's release constant, which is the function of the square root of time. Moreover, Higuchi's model followed the drug release by diffusion process as mentioned by Fick's law (Siepmann and Peppas, 2012; Jain and Jain, 2016). There are some assumptions to be followed by a system to exhibit Higuchi's model, as presented below:

- The initial drug concentration in the matrix needs to be sufficiently higher than the drug's solubility therein.
- The diffusion is unidirectional because the edge effects are negligible.
- The thickness of the dosage form is clearly greater than the size of the drug molecules.
- The matrix didn't swell or dissolve at all or very little.
- The diffusivity of the drug is constant.
- Establishing a perfect sink condition.

Any formulation that follows the above-said assumptions can follow the drug release by Higuchi's model. Researchers utilized Higuchi's model to describe the drug-release pattern. 5-FU liposomes were prepared using PL

90H and cholesterol and incorporated into a 1% chitosan solution after lyophilization to develop the liposomal gel. 5-FU was released from the developed liposomal gel following Higuchi's model (Glavas-dodov et al., 2005). The pH-sensitive hydrogel was developed for levothyroxine-Na pentahydrate using chitosan/arabinogalactan. Higuchi's model, which uses a Fickian diffusion release mechanism and has the greatest R^2 value (0.968), was deemed to be the best release model (Tapdiqov et al., 2022). Ciprofloxacin-loaded nano-biodegradable capsules were developed using chitosan + dextran sulfate. An in vitro release investigation was carried out in distilled water and PBS with pH values of 1.2, 4.5, and 7.4. The Higuchi model was found to be the most closely matched model across all media (Geetha Devi et al., 2021). Nimodipine-containing PLGA nanoparticles were created to treat posthemorrhagic cerebral vasospasm. A mixture of ethanol and PBS (1:1) was used to conduct the in vitro release examination, and the Higuchi model was determined to be the best-fitted model (Bege et al., 2013). Similarly, Higuchi kinetics was reported by various researchers such as docetaxel NPs prepared with chitosan (Jain et al., 2014), aceclofenac NPs using Eudragit RL-100 (Katara and Majumdar, 2013), ellagic acid NPs using PLGA-polycaprolactone (Sonaje et al., 2007), alpha lipoic acid cubosomes using glyceryl mono-oleate (Sherif et al., 2014), capsaicin cube phase gels using GMO and propylene glycol (Peng et al., 2010), carbamazepine nanoemulsion using castor oil (Kelmann et al., 2007), curcuminoid SLNs using GMS and stearic acid (Tiyaboonchai et al., 2007), bixin SLNs using GMS (Prathyusha et al., 2014), gatifloxacin SLNs using compritol/gelucire/stearic acid (Kalam et al., 2013), and metronidazole liposomes (Go, 2006), etc.

11.7.2.4 Hixson and Crowell's cube root law

Hixson and Crowell developed an equation that represents the rate of dissolution based on the cube root of particle weight and does not require that particle radius be constant for drug powder with uniformly sized particles (Hixson and Crowell, 1931). The generated equation after integration was applicable for the dissolution of compact material:

$$w_0^{1/3} - w^{1/3} = K_{\mathrm{HC}} t \tag{11.18}$$

where, w_0 denotes the initial weight of drug in the formulation, w denotes the weight of drug remaining to be released in the system at a specific time, and K_{HC} denotes the Hixson and Crowell release constant. For this model, a graph can be obtained by plotting the cube root of the amount of the

drug still to be released or present in the drug carrier versus time. The slope of the graph will reveal the release constant value (Ramteke et al., 2014).

The aforementioned formula is applicable to delivery systems like tablets in which dissolution takes place in planes parallel to the dosage form surface, and this surface reduces correspondingly with time while the geometric form is constant.

Regarding the concentration, density, and number of spherical particles (N) the above equation can be modified as

$$w_0^{\frac{1}{3}} - w^{\frac{1}{3}} = K' \frac{\sqrt[3]{NDC_s t}}{\delta} \tag{11.19}$$

where C_s is the saturation solubility at a given temperature, N is the number of particles, K' is a constant relating surface, form, and particle density, D is the diffusion coefficient, and δ is the thickness of the diffusion layer (Bruschi, 2015b).

It is well-known that surface factors of cubic or spherical particles are considered constant if the dissolution is constant throughout the entire system.

For irregular particles, the above equation can be modified. Moreover, dividing by $w_0^{1/3}$ the equation can be further simplified as follows:

$$\sqrt[3]{1} - f_i = 1 - K_\beta t \tag{11.20}$$

where K_β is known as the release constant, $f_i = 1 - (w/w_0)$ = fraction of drug release at time t. When the nonreleased fraction's cubic root is related to time, the above-mentioned equation reflects a linear function. This is accurate if the equilibrium circumstances remain unchanged and the particle's surface continues to gradually degrade with time (Bruschi, 2015b). The drug release is thought to be constrained by dissolution velocity in this model rather than diffusion, which can take place via the polymeric matrix (Bruschi, 2015b).

Danielly L.A. Sittaa and co-workers developed cross-linked albumin microparticles containing vitamin B12. A dissolution study was conducted in a dissolution medium of different pHs (2, 6, and 10) using a dialysis technique to evaluate the effect of the erosion matrix. Application of the Hixson–Crowell model confirmed the erosion mechanism (Sitta et al., 2014).

11.7.2.5 Korsmeyer–Peppas model

A more comprehensive semiempirical method created by Korsmeyer and coworkers (1983) and Ritger and Peppas (1987) to characterize the release of drugs from the polymeric system is also referred to as a power law (Bhansali, 2021; Bruschi, 2015b). An exponential correlation between the percentage of drugs released and time was established by the Korsmeyer–Peppas model (Korsmeyer et al., 1983; Ritger and Peppas, 1987):

$$f_i = \frac{M_t}{M_\infty} = Kt^n \tag{11.21}$$

Taking the log of the above equation:

$$\log\left(\frac{M_t}{M_\infty}\right) = \log K + n \log t \tag{11.22}$$

where M_t and M_∞ denote the amount of drug released at time t and after the establishment of equilibrium or infinite time, respectively. The ratio of M_t/M_∞ is known as the fraction of drug release (f_i). K denotes the release velocity constant. It is associated with the structural modification and geometrical characteristics of the system, n is known as the release exponent as a function of time. It is helpful to decide the release mechanism. The power law is applicable to depict the release of drugs from a polymeric system like hydrogels. A number of researchers have utilized a modified version of this equation that included the latency time (l) which indicates the time taken by the formulation to start drug release from the system.

$$\frac{M_{(i-l)}}{M_\infty} = K(t-l)^n \tag{11.23}$$

Taking the log of the above equation

$$\log\left(\frac{M_{(i-l)}}{M_\infty}\right) = \log K + n \log(t-l) \tag{11.24}$$

This equation was further modified by incorporation of the concept of the burst effect (b), i.e., an abrupt increase in the initial drug release as follows:

$$f_i = \frac{M_t}{M_\infty} = Kt^n + b \tag{11.25}$$

When a polymeric system comprises an unknown drug-release mechanism or more than one sort of release mechanism, researchers do well by applying the power law.

Researchers do justice with the application of power law when there is an unknown release mechanism or more than one sort of release mechanism involved in a polymeric system.

Simply, It is presumed that two independent drug transport mechanisms are involved *viz* relaxation and diffusion. The value of the release exponent (n), as given in Table 11.2, determines the drug's release profile in a matrix. Two mechanisms could be involved:

(a) Fickian type (case I)

(b) Non-Fickian type (case II, anomalous and super case II)

- Fickian diffusion (case I) describes DDS where the rate of diffusion is higher compared to the rate of polymer relaxation and swelling. Therefore, the release is managed by the diffusion process.
- DDS with non-Fickian diffusion (case II) has the release regulated by polymer relaxation and swelling.
- Last but not the least, super case II transport is an extreme example of a transport mechanism in which the polymer chains snap (known as solvent crazing) during sorption of the solvent.

In the literature, the applicability of the Korsmeyer—Peppas model is well justified. C.S. Dhanya and coworkers developed rhodamine B lauric

Table 11.2 Mechanism of drug release from the polymeric matrix based on the value of release exponent and geometry (Bruschi, 2015b; Kosmidis et al., 2013).

S. no.	Drug transport mechanism	Shape	Value of n
1	Fickian model	Planar (thin film)	0.50
		Cylinders	0.45
		Spheres	0.43
	Non-Fickian model		
2	Anomalous type	Planar (thin film)	$0.5 < n < 1.0$
		Cylinders	$0.45 < n < 0.89$
		Spheres	$0.43 < n < 0.85$
3	Case I transport	Planar (thin film)	1.0
		Cylinders	0.89
		Spheres	0.85
4	Super case II transport	Planar (thin film)	>1
		Cylinders	>0.89
		Spheres	>0.85

acid SLNs for lymphatic absorption via oral delivery. The drug-release study was conducted in pH 7.4 PBS and various models were applied to investigate the drug-release kinetics. Korsmeyer–Peppas's model was found to fit best with an R^2 value of 0.984. The release exponent (n) was 0.222, indicating the Fickian type of drug diffusion (Dhanya et al., 2023). Chitosan nanoparticles for doxorubicin were reported by Muhammad Usman Akram. The initial drug release followed the Korsmeyer–Peppas model with the highest R^2 value of 0.995 followed by the Fickian-type diffusion with a release exponent value of 0.420 (Akram et al., 2023). Utilizing HPMC, chitosan, Carbopol 934P, and NaCMC, rivastigmine in situ gels have been produced. An in vitro drug-release study was conducted in a simulated nasal electrolyte solution (SNES, pH 5.5) at 35°C ± 0.5. Release kinetics followed the Korsmeyer–Peppas model with a non-Fickian (anomalous) mechanism indicating that drug release was controlled by the erosion-diffusion mechanism (Abouhussein et al., 2018).

11.7.2.6 Baker and Lonsdale model

In 1974, a model was put up by Baker and Lansdale to explain how drug is released from a spherical-type DDS. This is also known as the modified Higuchi's model.

$$f_1 = \frac{3}{2}\left[1 - \left(1 - \frac{M_t}{M_\infty}\right)^{2/3}\right] - \frac{M_t}{M_\infty} = KT \tag{11.26}$$

where, M_t and M_∞ are the amount of drug released at time t and infinity, respectively. K is known as the release constant that corresponds to the angular coefficient of the curve (inclination). The slope of a graph obtained from the curve plotted between $d(\frac{M_t}{M_\infty})/dt$ and root of time inverse can be used to determine the value of K. The linearization of drug-release data from spherical systems, such as microspheres and microcapsules, is possible using this approach (Costa and Sousa Lobo, 2001; Shaikh et al., 2015). Shailesh and associates developed anionic drug containing pellets for CDD. Various models have been applied to find the release kinetics, but that of Baker and Lonsdale was found to be the best-fitting model (Singh et al., 1996).

11.7.2.7 Brazel and Peppas model

Many attempts have been made to describe solvent penetration and drug release from the polymeric matrix system. According to this model, the

diffusional Deborah number (De) and swelling interface number (Sw) are two dimensionless parameters that are used to describe the water absorption/penetration, swelling, and drug release for many polymer and solvent systems. De establishes a relation between the motion of water and polymer relaxation rate (Elmas et al., 2020; Brazel and Peppas, 2000). Sw measures water penetration in the polymer chain relative to the diffusion of a dispersed drug out of the polymer. Both constraints are influenced by the properties of the polymer and drug. Mathematically,

$$\mathrm{De} = \frac{\Lambda}{\Theta} = \frac{\Lambda D_{1.2}}{(\partial(t))^2} = \frac{\text{Relaxation time}}{\text{Time of solvent diffusion}} \tag{11.27}$$

where Λ is known as the relaxation time when subjected to swelling stress, Θ is the diffusion time of the swelling matrix. In this case, the Fickian process, which is a function of time, will determine whether water diffusion ($D >> 1$) or relaxation time ($D1$) dominates the swelling. If D is nearly 1, then two processes will occur simultaneously leading to the anomalous transport mechanism (Brazel and Peppas, 2000).

On the other hand, the swelling interface number (Sw) is the balance/equilibrium/ratio of water (solvent) penetration to drug (solute) release.

$$\mathrm{Sw} = \frac{\nabla \partial_r}{D3,21} = \frac{\Lambda D_{1.2}}{(\partial(t))^2} = \frac{\text{Solvent mobility}}{\text{Drug diffusion}} \tag{11.28}$$

where Λ denotes the velocity of the moving glassy/rubbery front, ∂ denotes swollen gel layer thickness, and $D3,21$ denotes the diffusion coefficient. Sw depends upon polymer and drug properties. In both situations of Sw values, either $<<1$ or $>>1$, the water penetration or diffusion controls the release, and time dependence will be as per the Fickian law. If Sw is close to 1, the release is directed by anomalous transport (Brazel and Peppas, 2000).

11.7.2.8 Hopfenburg model

In order to forecast drug release from polymers with eroding surfaces, Hopfenburg developed a mathematical model. During the erosion, the surface area remains constant. The release of poorly water-soluble drugs takes place through an erosion mechanism (Costa and Sousa Lobo, 2001; Jain and Jain, 2016). He examined how drugs are released from surfaces that have a variety of geometries, and he created a generic mathematical equation (Eq. 11.29) that describes how drugs are released from slabs,

spheres, and infinite cylinders that have heterogeneous erosion (Ramteke et al., 2014; Shaikh et al., 2015; Katzhendler, 1997).

$$\frac{M_t}{M_\infty} = 1 - \left[1 - \frac{K_0 t}{C_0 a_0}\right]^n \tag{11.29}$$

where, $\frac{M_t}{M_\infty}$ denotes the drug released fraction, K_0 denotes erosion grade constant, C_0 denotes initial drug concentration at time zero, a_0 denotes initial radius depending upon the geometry of the matrix, namely sphere ($a_0 = 3$) or cylinder ($a_0 = 2$), or half of the thickness of the film ($a_0 = 1$).

The preceding equation was updated by El-Arini and Leuenberger (1998) to compute the latency time (l) as follows:

$$\frac{M_t}{M_\infty} = 1 - [1 - K_1 t\,(t - l)]^n \tag{11.30}$$

where $K_1 = \frac{K_0}{C_0 a_0}$. According to this model, matrix erosion is considered as the rate-controlling step in the drug release. Time-dependent diffusing resistance internal and external to the eroded matrix does not have any influence on the drug release kinetics (Katzhendler, 1997). The drug release mechanism from optimized oily spheres which exhibited the site-specific biphasic release pattern that can be evaluated by the application of this model (Dash et al., 2010; Sibanda et al., 2004).

11.7.2.9 Weibull model

This is a distribution function-based model and was first put forward by Weilbull (1951), and which Langenbucher (1972) modified to its present form. This model explains the events and processes occurring within a limited time frame (Dash et al., 2010; Ramteke et al., 2014; Costa and Sousa Lobo, 2001). Drug accumulated in a solution system at time t can be explained by the following equation:

$$m = 1 - \exp\left(\frac{(t - T_i)^n}{a}\right) \tag{11.31}$$

In another format:

$$m = 1 - \exp^{-(t - T_i)^{\frac{b}{a}}} \tag{11.32}$$

where a and T_i represent the time scale parameter of the process and localization parameters and is known as the latency of the release process (maybe

zero also), respectively, and b denotes the shape of the dissolution curve (form parameter). The value of the form parameter b is a variable such as:

(a) $b = 1$ (exponential) = In this case the shape of the curve corresponds to the exponential profile k (constant) value $1/a$

(b) $b > 1$ = In this case the shape of the curve will be sigmoid, with ascendant curvature delimited by an inflection point

(c) $b < 1$ = In this case the shape of the curve will be parabolic, displaying high initial slope and a consistent exponential character.

The drug release from the matrix systems is compared using this model. Sittaa and co-workers developed cross-linked albumin microparticles containing vitamin B12. The release study was conducted at different pHs (2, 6, and 10). They concluded that the Weibull equations govern the release profile of vitamin B12 from the matrix during the preliminary stage of the investigation (pH 2), whereas the super case II transport mechanism results from diffusion, relaxation, and erosion during the second stage of the study (pH 6 and 10) (Sitta et al., 2014).

11.7.2.10 Peppas–Sahlin model

According to this model, during drug release in an anomalous process, the two contributing mechanisms, namely diffusional and relaxational, are involved. This can be seen by the following equation:

$$\frac{M_t}{M_\infty} = K_1 t^m + 2_2 t^{2m} \tag{11.33}$$

where, $K_1, K_2,$ and m are constants.

The first component in the equation stands for the Fickian diffusional contribution (F) and the second term stands for the Case II relaxational contribution (R). For any system with any geometrical shape and a controlled release pattern, the coefficient m is the exponent of pure Fickian diffusion (Shaikh et al., 2015; Peppas and Sahlin, 1989). Another coefficient m is related to the power law coefficient (n) and can be given for any shape, such as films, cylinders, and spheres (Bruschi, 2015b).

11.7.2.11 Gompertz model

This is the simple exponential model used to describe the drug-release mechanism, which can be mathematically presented as follows:

$$M_t = M_{\max} \exp\left(- \alpha \, e^{\beta \log t} \right) \tag{11.34}$$

where M_t is the percentage drug dissolved/100, M_{max} is the maximum amount of drug dissolved, α is the location or scale parameter, indicating the undissolved drug at time $t = 1$, and β denotes the shape parameter indicating the dissolution rate/time. This model begins with a sharp increase and converges gradually to the asymptotic maximal dissolution. This approach is more explicitly applicable in the case of an intermediate-release formulation of a drug with good solubility (Dash et al., 2010; Costa and Sousa Lobo, 2001; Shaikh et al., 2015; AlMajed et al., 2022).

11.7.3 Regression model analysis

Regression model analysis is used for the optimization of pharmaceutical formulation using various software such as Minitab, expert design, etc. Data (response) associated with dissolution/release is fitted to certain models like linear, 2F, and quadratic models, to detect the value of the regression coefficient (R^2) (Ladani Ravi, 2010). The model that exhibited the highest R^2 value is considered an optimized model. In the case of regression modeling, responses (like drug dissolved, disintegration, entrapment efficiency, particle size, etc.) are chosen as dependent parameters, and independent parameters may include polymer concentration, surfactant concentration, etc. (Li et al., 2008). The effect of independent constraints is observed on dependent constraints and can be displayed by diagrams (3D, contour), polynomial equations, etc. The following models are mainly used.

11.7.3.1 Polynomial equation for the linear, first-order, and quadratic models

The polynomial equation for the linear model exhibited the individual and interaction effect of independent parameters (X, $X2$, $X3$) on the dependent parameters (Y, response) effect (Noorulla et al., 2022; Yasir et al., 2022). The equation carries the charge, negative or positive. A positive charge displayed a positive effect of the independent parameter on the dependent parameter (response) while a negative sign showed an adverse influence on the response. The polynomial equation for the linear model can be depicted as:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 - \beta_3 X_3 - \beta_{12} X_1 X_2 + \beta_{13} X_1 X_3 + \beta_{23} X_2 X_3 \tag{11.35}$$

where, Y is the response (like CDR), β_0 is a constant obtained from the intercept, $\beta_1, \beta_2, \beta_3$ are regression coefficients, whereas $\beta_{12}, \beta_{13}, \beta_{23}$ are known as the interaction coefficient. X_1, X_2, X_3 are the formulation factors (independent parameters) that influence the response (like CDR). In the

above model equation positive signs like $+\beta_1 X_1$ mean the factor X_1 exhibited a positive effect on response Y i.e., if X_1 value will increase simultaneously Y will also increase, or vice versa. In the above model equation, negative signs like $-\beta_2 X_2$ mean the factor X_2 exhibited a negative effect on response Y, i.e., if X_2 value will increase simultaneously Y will decrease, or vice versa.

Similarly, the polynomial equation for the quadratic model (Yasir et al., 2018) can be represented by adding the quadratic term (X^2) in the above equation as:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 - \beta_3 X_3 - \beta_{12} X_1 X_2 + \beta_{13} X_1 X_3 + \beta_{23} X_2 X_3 - \beta_{11} X_1^2 + \beta_{22} X_2^2 + \beta_{33} X_3^2 \tag{11.36}$$

11.7.4 Nonlinear regression models

For the comparison of certain characteristics like amount of drug diffused or dissolved or the rate of dissolution, the percentage of drug released or dissolved at a specific point, analysis of variance (ANOVA) can be used. In this case, two types of effects are considered, namely fixed and random effects. The variables like the nature of the dissolution medium (pH, presence of enzyme/presence of surfactants), temperature, spindle speed, etc (Qazi et al., 2003). that researchers can control are called fixed effects. Typically, selection of levels from a large population is used to create random effects (Dash et al., 2010). In the case of dissolution, DDS like tablets or capsules act as a random effect. Each tablet is chosen from a larger population of tablets, and assumptions about the population variance from which the sample has been taken can be made based on the tablet-to-tablet variation in each scenario (Qazi et al., 2003). However, once the ANOVA analysis has determined the key components, a nonlinear regression model can be used to demonstrate the link between the important parameters. Nonlinear regression models have the advantage of allowing for the differentiation of dissolution parameters even when the overall dissolution profiles are comparable. This is due to the fact that the dissolution process in the nonlinear regression model depends on the kinetic constant and diffusion exponent, and that different combinations of the two parameters might lead to profiles of dissolution that are identical. Nonlinear regression

can be applied with the aid of the JMP software (Dash et al., 2010; Qazi et al., 2003). The relationship between important factors will be clarified through the data analysis utilizing nonlinear regression models, which will also guarantee that future preparations will not exceed permissible dissolution requirements (Qazi et al., 2003).

11.7.5 Model-independent approach

Moore and Flanner established two model-independent indices in 1996 for identifying similarities and differences between the release profile for two formulations (one may be standard and the other may be a test formulation). These are known as similarity (f_2) and dissimilarity (f_1) factors. Differences in the release profile of two formulations at each time point can be determine by the dissimilarity (f_1). This estimates the relative error of the two curves. Mathematically, the dissimilarity (f_1) factor can be denoted by Eq. (11.37) (Dash et al., 2010; Costa and Sousa Lobo, 2001; Jain and Jain, 2016):

$$f_1 = \frac{\left[\sum_{t=1}^{n}(R_t - T_t)\right]}{\sum_{t=1}^{n} R_t} \times 100 \tag{11.37}$$

where n denotes the number of time points for the dissolution study, and R_t and T_t denote the amount (or %) of drug dissolved at each of the selected n time points for the reference and test product, respectively (Costa and Sousa Lobo, 2001; Bhansali, 2021). Mathematically, the similarity factor (f_2) can be calculated by the following equation:

$$f_2 = 50 \log \left\{ \left[1 + \frac{1}{n} \sum_{t=1}^{n} (R_t - T_t)^2 \right]^{-0.5} \times 100 \right\} \tag{11.38}$$

Similarity and dissimilarity factors determine how similar two release profiles are at particular time points. There should be a minimum of 12 units of each product compared to at least three separate time periods. The standard deviation should not be greater than 10% at any given time point for the test or reference. According to guidelines of Food and Drug Administration (FDA) range of f_1 and f_2 should be 0–15 and 50–100 respectively, to indicate the similarity between the two profiles

(e.g. dissolution profile, drug release profile, etc.) (Sheth, 2021; FDA Guidance for Industry, December 2017). Tulsi Sagar Sheth and co-workers optimized the similarity factor by utilizing linear regression (Costa and Sousa Lobo, 2001; Sheth, 2021). The value of the similarity factor was found to be 40.

Paramita Saha and co-workers developed rotigotine redispersible nanoemulsion for brain targeting via the nasal route. In a PBS 6.4 pH buffer, a comparative in vitro dissolution test for pure drug and rotigotine-loaded lyophilized nanosuspension was performed, and the similarity factor was calculated. The fact that the f_2 was below 50 indicates that the two dissolution profiles are not comparable (Saha et al., 2023). The dissolution profiles of various brands of amoxicillin were compared with the amoxicillin innovator capsules by Kassaye and colleagues. The USP-II dissolution apparatus was used to conduct the investigation in 900 mL of water. The f_2 was much lower than 50, illustrating the divergence from the innovator's dissolution profile (Kassaye and Genete, 2013).

11.8 How to select the best-fitting model

Coefficient of determination (R^2) is the most suitable parameter to select the best-fitting release model. For different models, the R^2 value is calculated and compared to others. The model that has the highest value closest to 1 is considered the best-fitting model. However, this is applicable when model equation parameters are similar. In the case of increasing the comparing parameters, the adjusted coefficient (R^2_{adj}), which can be determined by the following equation, is used to select the best-fitted model.

$$R^2_{adj} = 1 - \frac{n-1}{n-p}(1 - R^2) \tag{11.39}$$

Correspondingly, other statistical methods are employed to compare and select the most suitable models, including the correlation coefficient (R), analysis of variance (ANOVA), and multivariate analysis of variance (MANOVA) (Shaikh et al., 2015). A summary of the literature associated with various model and drug release mechanisms is presented in Table 11.3.

Table 11.3 The literature associated with various models and release mechanisms of certain formulations with the major polymers involved in their preparation.

API	Formulation type	Main excipient	Release study	Release model	References
Levonorgestrel	Microspheres	PLGA	DM: 0.9% w/v in distilled water + 0.5% sodium dodecyl sulfate DA: Stoppered Flask	Zero-order	Puthli and Vavia (2009)
Poly (ε-caprolactone)	Ocular insert	PCL-PEG-PCL	DM: PBS 7.4 DA: Closed glass bottle	Zero-order	Mariz et al. (2022)
Etofenamate	SLN	Precirol ATO 5	DM: PBS pH 7.4: ethanol (70:30) DA: Franz diffusion cell	Zero-order	Badilli et al. (2015)
Ibuprofen	Carboxymethyl cellulose/ mesoporous magnetic graphene oxide carriers	Carboxymethyl cellulose, graphene oxide	DM: Intestinal Fluid (pH 7.4) DA: Franz diffusion cell	First-order	Pooresmaeil et al. (2020)
Methotrexate (MTX)	Microspheres	Chitosan	DM: PBS pH 7.4	First-order and Higuchi's model	Dubey and Parikh (2004)

Ibuprofen and ketokonazole	Tablets	–	DM: FaSSGF, FeSSGF, FaSSIF-V2, and FeSSIF-V2 Volume: 500, 300, 40 mL	Dissolution profiles of Ibuprofen and ketoconazole differ in different dissolution mediums and in different volumes also	Jamil et al. (2021)

11.9 Conclusion and future perspectives

The chapter summarizes drug-release modeling from the bioresorbable polymeric matrix system. A huge number of natural and synthetic bioresorbable/biodegrdable polymers have been used for the design of DDSs based on sustained and controlled drug-release patterns. These polymers should be nontoxic, biocompatible, nonallergic, bio-stable, etc. Many researchers and scientists have designed and proven their capabilities to encapsulate the drug and transform them into nanocomposites such as nanoparticles, nanocarriers, hydrogels, metal, and metal oxide components, etc. In vitro release studies have been recognized as one of the main criteria to evaluate and optimize the formulation. In vitro release studies have shown the structure—function relationship of the material matrix, helped customize the materials for the best-regulated release, and also provided an idea about the in vivo performance of the developed formulations. Several mathematical models are reported in the literature, which have been used to describe the relevant kinetics and mechanisms of drug release from the biodegradable polymer matrix or biodegradable DDS. Mathematical modeling provides the relation between the drug dissolution/release and the geometry of the matrix. Statistical models, model-dependent approaches, and model-independent approaches are used currently. Application of the statistical approach is somewhat complicated, while model-dependent approaches offer an acceptable and are commonly used for drug-release kinetic studies. This approach provides a true correlation between dependent and independent dissolution parameters. The model-independent approach, on the other hand, is based on the value of similarity (f_2) and dissimilarity (f_1) factors, which are sensitive to the dissolution point taken during the study. However, the established similarity or dissimilarity between the dissolution profiles is not clear. Additionally, the goal of mathematical modeling is to explain drug-release kinetics and mechanisms, especially in association with the structure—function relationship of the material system. They can also be helpful in establishing the relationship between in vitro dissolution with in vivo absorption. Therefore, having a solid understanding of the principles will help with future device and material development.

Regarding future perspectives, a perfect model that can establish a better correlation between in vitro and in vivo dissolution is unavailable. This might be due to differences in the dissolution medium of in vivo atmosphere and in vitro condition. Body physiological conditions are highly

complex as compared to the PB used for the in vitro dissolution. After reaching the DDS in the body, the release profile of a drug may be influenced by different proteins, cells, and enzymes present at the site of drug dissolution. Therefore, mathematical models that can provide a real correlation of physiological conditions with an in vitro medium are still required to be developed (Fu and Kao, 2010).

The release pattern of SRDDS or CRDDS is usually characterized by the initial burst release, and typically followed by sustained release. The burst release helps to keep the appropriate drug-loading concentration fairly quickly. Burst release is frequently associated with the device's shape, the coating material's surface characteristics, the distribution pattern of API within the polymer matrix, the intrinsic dissolving rate of the API, the heterogeneity of the matrices (pore density), and other parameters. There have not been many investigations into the development of mathematical models for burst release that are based on mechanisms. Therefore, it would be beneficial to create models that explain the burst release mechanisms in order to improve the prediction of the burst release.

List of abbreviations

API	Active pharmaceutical ingredient (drug)
CDR	Cumulative drug release
CR	Controlled release
CRDDS	Controlled-released drug-delivery system
DDS	Drug-delivery system
DS	Delivery system
NDDSs	Nano-drug-delivery systems
NLC	Nanostructured lipid carrier
NP	Nanoparticle
PCL	Polycaprolactone
PDS	Polydioxanone
PGA	Poly(glycolic acid)
PLGA	Poly(lactic acid-co-glycolic acid)
PN	Polymeric nanoparticle
PVA	Polyvinyl alcohol
SA	Surface area
SLN	Semi-solid lipid nanoparticle
SR	Sustained release
SRDDS	Sustained-release drug-delivery system

CHAPTER 12

Bioresorbable polymers: A prospective utilization as an implant

Shuai Chen[1], K. M. Faridul Hasan[2] and Xiaoyi Liu[3]
[1]Department of Biochemistry and Molecular Biology, College of Basic Medical Sciences, Guizhou Medical University, Guiyang, China; [2]Simonyi Károly Faculty of Engineering, University of Sopron, Sopron, Hungary; [3]The Key Laboratory of Environmental Pollution Monitoring and Disease Control, Ministry of Education, Department of Nutrition and Food Hygiene, School of Public Health, Guizhou Medical University, Guizhou, China

12.1 Introduction

A bioabsorbable polymer is a kind of polymer material that can be degraded by enzyme or chemical action in vivo (Li et al., 1998). According to the source, bioabsorbable polymers can be divided into natural polymers and artificial polymers, among which natural bioabsorbable polymers mainly include chitosan, collagen, etc. (Li et al., 2021). They are mainly isolated from biological tissues; artificial absorbable polymers include polyglycolide, poly-lactide and poly-hydroxybutyrate. The main general formula is the derivative of α-hydroxy acid of HO-CHR-COOH, and the R groups of H and CH_3 correspond to glycolic acid and lactic acid, respectively (Mukherjee and Pietrzak, 2011).

The development of modern medical science is often inseparable from materials science, especially the development of medical biomaterials. With their own characteristics, bioabsorbable polymers are widely used as implants in cosmetic shell, tissue repair, cardiovascular intervention, tissue engineering, and other major medical fields. Bioabsorbable polymers can be decomposed by enzyme or chemical decomposition after implantation, so there is no need for concerns about permanent implantation or surgical removal, so they can be implanted temporarily to promote the repair and fixation of damaged tissue. These include bioabsorbable sutures and small bones, for example, Li and Sun (2022) indicated that silk fibroin-based biomaterials could be used in tissue engineering, playing a very important

Bioresorbable Polymers and their Composites

role in tooth and mandible tissue, cartilage, skeletal muscle, and vascular tissue. Meanwhile, De la Harpe et al. (2022) synthesized a new type of bioabsorbable suture with sodium alginate, pectin, and gelatin. This product did not only meet the basic requirements of suture materials, but also filled the gap of bioabsorbable polymer sutures in the medical market. In addition, Kim et al., (2022) synthesized a new type of fatty amide polyurethane urea elastomer and coated it on a biodegradable metal coil to prepare a bioabsorbable embolization device for cerebral saccular aneurysms. The biodegradable metal coil was used to protect against cerebral aneurysms. In general, bioabsorbable polymers are a kind of biomaterial that can be used as implants to replace injured or diseased tissues and organs, promote wound healing, such as absorbable sutures, bone nails, and bone plates, and even improve and correct tissue function.

In addition, the development of bioabsorbable polymers as implants also benefits from the rise of technologies such as 3D printing. 3D biological printing has become a new method to obtain complex biological structures, through accurate and controlled layer-by-layer assembly, using cells, bioabsorbable polymers, or bioactive molecules as biological ink, and finally obtain their own biological structure. For example, cold atmosphere plasma surface modification can quickly and cheaply enhance 3D printing potential applications of polylactic acid bone tissue engineering materials (Wang et al., 2016). Yi et al. (2016) claimed that 3D printing patches composed of bioabsorbable polymers could be used for long-term delivery of anticancer drugs, suggesting that 3D printing might be an effective method for local delivery of chemotherapy to treat cancer. Sun et al. (2020) found that a new biocompatible absorbable material (lactide-ethanol ester-1myr3-trimethylene carbonate; LA-GA-TMC) could be used to manufacture a cardiac septal defect occluder using 3D printing technology.

Natural bioabsorbable polymers have better bioabsorption and low toxicity, while artificial bioabsorbable polymers have good mechanical strength and controllability of chemical and physical properties such as the polymer degradation rate (Mohammadi Nasr et al., 2020; Hong et al., 2021). Also, with the progress in manufacturing technology, such as 3D biological printing, the emergence of technology has brought ideas for the production of more complex structures, which is extremely helpful for the application of bioabsorbable polymers (Abasalizadeh et al., 2020; Jammalamadaka and Tappa, 2018). As implants, bioabsorbable polymers can be

hydrolyzed or enzymatically hydrolyzed into small molecules and then excreted from the body, removing concerns about the risk of permanent implantations and so they are widely used as temporary implants to promote the repair of damaged tissue. The most common example is bioabsorbable sutures. With an understanding of biomaterials, various methods can be used to change the mechanical strength of bioabsorbable polymers, giving them more application prospects. For example, the mechanical strength can be enhanced so that they can be used in orthopedic fixation devices such as screws and plates, and then used to treat fractures, or in orthodontics and orthopedic surgery. Bioabsorbable polymers can also be made into artificial skin, such as chitosan, which can be used to cover a wound to stop bleeding, fight infection, and promote wound healing (Jiménez-Gómez and Cecilia, 2020). Bioabsorbable polymers as implants are widely used in surgery, and the scope of applications for biomaterials with different properties is also different. Bioabsorbable polymers are used as temporary implants to heal the injured tissue, their main function being to reduce the wound size and promote healing. When used in orthodontics or plastic surgery, they mainly are used in a supporting or fixed role. Bioabsorbable polymers degrade slowly with the growth of the tissue, with new tissue filling the space of the original bioabsorbable polymer.

Natural or artificial bioabsorbable polymers can also be used as implants as carriers or media for drug release in the body, so that drugs can reach a specific concentration in a specific time and space to achieve therapeutic purposes (Langer, 1990). For example, Wei-Hong Jian et al. used nanohybrid hydrogel of sulfated glycosylamine polyelectrolyte composite nanoparticles (PCNs) to control the transmission of matrix-derived factor-1 α (SDF-1 α) and basic fibroblast factor (bFGF) to regulate the transmission of endogenous neural stem cells to treat brain injury, and confirmed their conjecture through systematic in vivo and in vitro experiments (Jian et al., 2018). The bioabsorbable polymer drug-delivery device realizes local control of the drug concentration and greatly reduces the nonspecific distribution of drugs in normal tissues, so as to improve the therapeutic effect and reduce drug side effects. However, at the same time, there are some shortcomings such as unexpected degradation products (Khandare and Haag, 2010). As widely used biomaterials, bioabsorbable polymers are also used regularly in tissue engineering. The purpose of tissue engineering is to develop tissue or organ substitutes with biological functions (Guo and Ma, 2018).

Three conditions are needed to reorganize the damaged tissue: (1) seed cells of damaged tissue; (2) suitable scaffold material; and (3) chemical signals that induce cell proliferation and differentiation (Janoušková, 2018). By combining seed cells with scaffold materials, scaffolds act as extracellular matrix, and chemical signals induce cells to proliferate and differentiate into functionally mature adult cells to achieve the purpose of artificial organs. Scaffolds play a key role in tissue engineering (Lekshmi et al., 2020). Excellent bioabsorbable polymers can also be used as scaffolds for a variety of tissue engineering purposes. For example, polycaprolactone (PCL) is used not only in bone (Park et al., 2020), skeletal (Choi et al., 2008), muscle, and nerve tissue regeneration (Alvarez-Perez et al., 2010), but also in cardiovascular regeneration (Tillman et al., 2009). The emergence of tissue engineering provides a new method to speed up tissue healing and improve the quality of life of patients with organ defects, and provides a new way to solve the shortage of organ transplant donors.

Next, the characteristics of bioabsorbable polymers as implants, focusing on their applications in various aspects, in order to provide some reference for follow-up research, are discussed.

12.2 Characteristics of bioabsorbable polymers as implants

The most significant role of bioabsorbable polymers is mainly based on their characteristics (Fig. 12.1).

12.2.1 Good biocompatibility

Biocompatibility is a biological characteristic in which a material that is in the process of dynamic change in an organism, can withstand the action of the host system and remain relatively stable and not be rejected or destroyed, which is also known as biological adaptability and biological acceptability. The interaction and influence between the implant and the body continue until balance is reached or the implant disappears completely. Generally speaking, an implant reacts with the host's body, as determined by the physical or chemical properties of the implant, including inflammation, cytotoxicity, or corrosion of the implant (Zhiqiang et al., 2022).

12.2.2 Sufficient mechanical strength

Bioabsorbable polymers can provide support and fixation through compression and bending strength, and should be easy to implant (Liu et al., 2022),

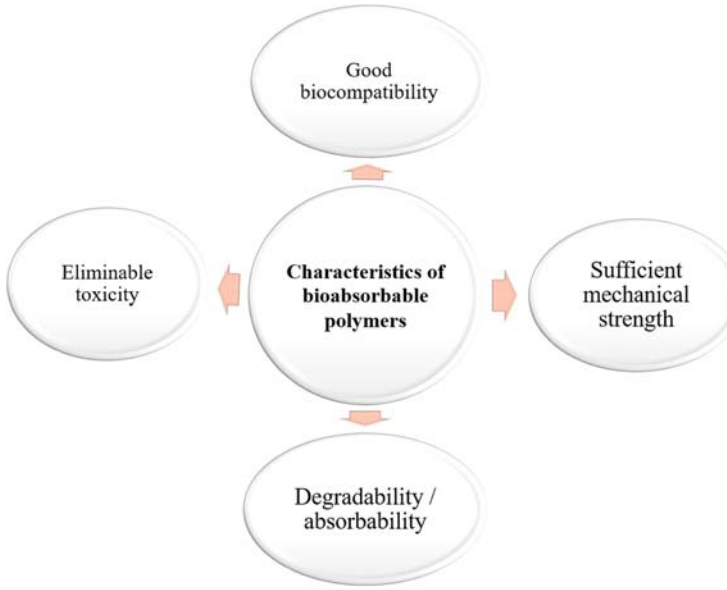

Figure 12.1 Characteristics of bioabsorbable polymers.

such as for fixation in orthopedics (Figueiredo et al., 2020), vascular scaffolding (Albaghdadi et al., 2017), and other areas of the use.

12.2.3 Degradability/absorbability

When the body tissue recovers, it is gradually degraded and replaced by normal tissue, therefore it does not need to be removed by a second operation. Also, it can be used as a drug-delivery system to release the drug locally and achieve the desired therapeutic effect (Mouriño and Boccaccini, 2010), such as bone repair that is carried out using bioabsorbable polymers containing antibiotics (Coraca-Huber et al., 2012).

12.2.4 Eliminable toxicity

Effective antiinfection protection in the process of implantation and recovery means that it can be used as an implant in various nonpermanent fixations, such as maxillofacial surgery (On et al., 2020) or bone remodeling (Majeed and Chowdhury, 2022), and it also can be used as a drug-delivery system to better control drug release and achieve a better therapeutic effect (Adekoya et al., 2022). Moreover, bioabsorbable polymers are also important materials in tissue engineering, which have an important impact on the construction of artificial tissues and organs (Li and Sun, 2022).

12.3 Application of bioabsorbable polymers

12.3.1 Application in implants for temporary fixation

By virtue of their characteristics, bioabsorbable polymers are widely used as temporary implants to help the body repair wounds, lift equipment for the body to support, and eventually degrade into nontoxic small molecules that can be excreted from the body. The main applications include absorbable sutures, drug-delivery devices, and orthopedic fixation devices, such as nails, plates, and needles. In addition, bioabsorbable polymers can also add drugs such as growth factors or antibiotics to further promote wound repair or antiinfection (Rousselle et al., 2019). Bioabsorbable polymers are mainly used in three areas, as shown in Fig. 12.2.

12.3.1.1 Application in orthopedics

Bioabsorbable polymer fixators have been used as a substitute for inert implants in orthopedics to prevent stress shielding and subsequent surgical removal of implants (Kainan, 2010). These bioabsorbable polymers are mainly made using polylactic acid and/or polyglycolic acid polymers, and self-reinforcing techniques are used to produce implants with sufficient

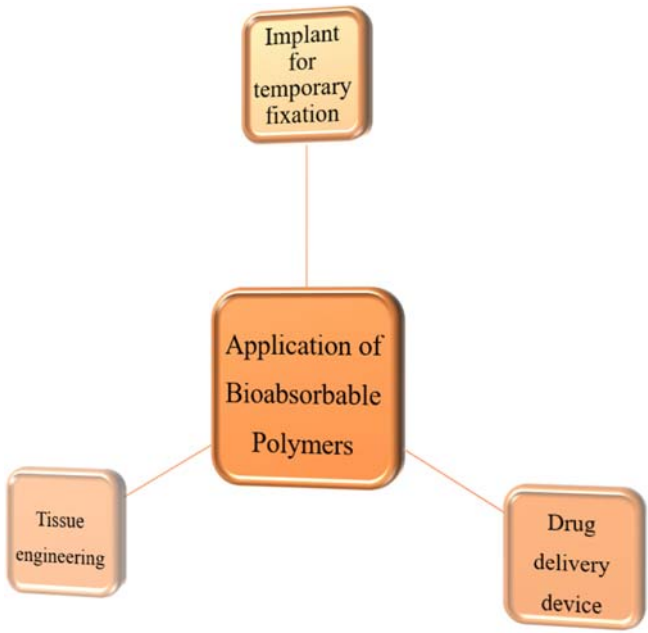

Figure 12.2 Applications of bioabsorbable polymers.

mechanical strength. The biological absorption time and treatments of different bioabsorbable polymers vary. There are bioabsorbable implants used for adults, some for children, and even different bioabsorbable polymers that are used at different sites, such as in the mandible, or in the extremities and skull (Peltoniemi et al., 2002).

Bioabsorbable polymers are increasingly accepted by orthopedic patients. They can be used to stabilize bone-to-bone fixation such as fracture, osteotomy, bone transplantation, and even to reconnect tendons, ligaments, meniscus fragmentation, and other soft tissues. They can be completely absorbed in the body, and so do not need to be removed by a second operation, thereby avoiding long-term interference in the surrounding tissue. Knee joint injury, cruciate ligament surgery, and meniscus injury have become the most common indications (Waris et al., 2004).

Hydroxyapatite poly-L-lactide (HPLLA) is a classical bioabsorbable polymer, which is composed of hydroxyapatite and poly-L-lactide (PLLA). Hydroxyapatite is widely used in craniofacial, hand, and joint repair operations (Sukegawa et al., 2016). HPLLA has good bone conductivity and can be uniformly degraded so that the body has little reaction to this foreign body. Satoshi Yanagibayashi's research showed that HPLLA screw pins could be used as fixation devices for phalangeal fractures, and also for comminuted fractures. The hydroxyapatite contained in HPLLA can be gradually and uniformly degraded and absorbed. In contrast, PLLA was not a complex, so its degradation rate was faster than HPLLA, and its degradation products were irregular and tended to gather in the same place, thus causing adverse foreign body reactions (Yanagibayashi et al., 2020).

In addition, RegJoint is also a bioabsorbable polylactic acid material introduced in 2011 and used in scapular and metacarpal interposition after trapezius resection of osteoarthritis. Dietrich et al. verified that the insertion of RegJoint implants did not cause adverse effects in 46 thumbs of 43 patients with symptomatic thumb arthritis who were treated with separate suspension arthroplasty (SA) and RegJoint insertiz (RJ) and followed up for at least 2 years (Dietrich et al, 2022).

In recent years, increasing attention has been paid to the adverse effects of inert in vivo implants, prompting clinicians and researchers to find more suitable fixators to improve the treatment, and a variety of bioabsorbable polymers have been developed for orthopedic treatment. Morandi et al. (2013) performed herringbone osteotomy to correct hallux valgus deformity from 2005 to 2010, and in their study group, 251 patients were fixed with distal metatarsal osteotomy with bioabsorbable needles (made of poly-

L-lactide and poly-DL- lactide), while those in the control group were fixed with conventional inert metal nails. After several years of follow-up, it was found that both bioabsorbable implant nails and metal nails could play a reliable role in fixation, not only for correction of hallux valgus deformity from a larger angle, but also for fewer foreign body reactions and a lower incidence of complications.

Bioabsorbable polymers can also be used for anterior cruciate ligament reconstruction to play a fixed role in surgery. The anterior cruciate ligament (ACL) is the inner ligament of the knee joint, which connects the femur and tibia and has important physiological functions such as maintaining the stability of the joint and helping to complete various movements. However, long-term strenuous lower limb movement or other factors can lead to its fracture, resulting in the interruption of the connection between the two bones, joint instability, and other sequelae (Zhichang, 2018). In the study by Thompson et al. (2016) by implanting Endobutton (Smith & Nephew) into the proximal end of the patient and fixing the distal end with a bioabsorbable screw made of amorphous low crystallinity PLLA, and after 16 years of continuous evaluation, they found that all patients had new bone formation after 16 years, although three patients developed cysts. However, it was not found that bioabsorbable screw implantation was related to adverse reactions such as survival or instability of anterior cruciate ligament implants.

12.3.1.2 Application in neurosurgery

Surgical treatment of complete transection of the sciatic nerve is usually by amputation, but this generally results in the patient spending the rest of their life in a wheelchair. Although limb salvage treatment is the first choice in some cases, especially in children or adolescents, patients often lose the opportunity for limb salvage due to various factors. Inada et al. (2017) not only provided objective evidence to prove that the sciatic nerve has strong potential for regeneration, but also selectively elongated the nerve to repair the nerve gap through the connection between the collagen-filled bioabsorbable nerve tube PGA-C and the broken end of the sciatic nerve, and gradually recovered the motor and sensory functions after operation, which greatly improved the quality of life of the patients.

Since Wigand first reported the repair of endoscopic cerebrospinal fluid (CSF) leakage in 1981, reconstruction of the skull base through nasal endoscopy in neurosurgery has gradually matured, successfully avoiding many complications such as meningitis, pneumocerebrosis, and cerebrospinal fluid

leakage. The conventional repair materials used in this operation include autogenous tissue and artificial materials, with the latter including bioabsorbable polymers such as fibrin glue and dura mater patches (Al-Asousi et al., 2017). Seaman et al. (2021) used a bioabsorbable polymer (DMAE L) lactic acid plate (Resorb-X Sellar Wall Plate; KLS Martin; Jacksonville, FL) to repair the skull base of the patient through a nasal endoscope. It has been demonstrated that a bioabsorbable polymer lactic acid plate could be used as a rigid implant for skull base repair through nasal endoscopic interventional implantation, and it has been objectively proved that this method has a good therapeutic effect for long-term integrity repair of exposed bone with a low complication rate.

12.3.1.3 Application in plastic surgery

The continuous updating of science and technology can also promote people to fulfill cosmetic surgery wishes, with breast reconstruction with implants are becoming increasingly acceptable. The acellular dermal matrix is an important part of breast reconstruction, but complete implantation of the acellular dermal matrix greatly increases the cost of operation. Sigalove et al. (2022) reduced the cost of surgery by using GalaFLEX-AlloDerm reconstruction; GalaFLEX is a biosynthetic grid derived from poly-4-hydroxybutyrate, which can be naturally degraded into water and carbon dioxide in vivo and completely absorbed within 18—24 months. Because it is harder and stronger than the acellular dermal matrix, it is particularly suitable for breast reconstruction, and this stability also reduces the implantation risks. By comparing GalaFLEX-AlloDerm reconstruction with AlloDerm reconstruction alone, they found that GalaFLEX-AlloDerm reconstruction not only did not increase the incidence of complications, but also had a lower rate of skin necrosis in the GalaFLEX-AlloDerm reconstruction group.

Augmentation rhinoplasty is usually used as a solution to indications such as wide lobule, deviation of the nasal septum structure, or frequent columella retraction, but the choice of rhinoplasty materials often determines the success of the operation. It also poses a challenge for surgeons to choose suitable implants and techniques. Autologous transplantation material is an ideal material for this graft, but the existing problems cannot be ignored, with the most direct problem being that the source is limited, and the site of implantation also carries a risk of infection. In recent years, bioabsorbable polymers have gradually replaced or supplemented other implant materials in rhinoplasty. Polycaprolactone (PCL) not only has good

flexibility, but also has the advantages of a slow degradation rate and good biocompatibility compared with other bioabsorbable polymers. Kim et al. reported that the implantation of fibrin/chondrocytes into PCL scaffolds designed by 3D printing can be used as implant materials for rhinoplasty, and the fusion of 3D printing and rhinoplasty will be the key to the realization of personalized rhinoplasty (Kim et al., 2015). Park et al. (2019) performed rhinoplasty with implants in patients with primary or secondary rhinoplasty using 3D-designed PCL stents, and verified the safety and effectiveness of PCL as a bioabsorbable implant in rhinoplasty through long-term follow-up. This can not only maintain its suitable shape, but also there is no foreign body reaction after operation. In addition, the function of patients with airway obstruction was also improved after the operation. As a kind of scaffold, PCL implants could improve the shape of the nose by migrating adjacent chondrocytes to form new cartilage tissue.

12.3.1.4 Application in the artificial skin

Artificial skin made of chitosan and its derivatives has good histocompatibility, softness, and antiinfection ability, which promotes wound healing (Liu et al., 2006). Yuan et al. (2021) used bioabsorbable poly(4-hydroxybutyrate) (P4HB) as a skin substitute, and SD rats as the research object to explore the relationship between P4HB and body-related inflammatory reaction. They found that P4HB could be used as a good skin substitute, which was very helpful in improving skin defects and wound healing.

12.3.2 Application in drug-delivery devices

The function of bioabsorbable polymer is not only that it can also be used as a carrier of bioactive substances such as growth factors, antibiotics, or various drugs. When a bioabsorbable polymer is slowly degraded in the body, the active substances or drugs are released locally, which makes the local drug concentration reach the therapeutic level, and avoids the adverse effects of drugs acting on the whole body. There are many kinds of polymers that can be used as drug carriers, including synthetic polymers such as polylactic acid co-glycolic acid (PLGA), poly(glycolic acid) (PGA), polylactic acid (PLA), polycaprolactone (PCL), and natural polymers such as chitosan, sodium alginate, gelatin, etc. The polymer represented by chitosan has become a research hotspot because it can be used as the carrier of macromolecular drugs such as vaccines, peptides, or proteins. As a drug-delivery device, bioabsorbable polymer has the advantages of high efficiency, low toxicity, and targeting.

12.3.2.1 Absorbable implant coating application in orthopedics

Despite the continuous optimization of surgical methods and implants, various complications of orthopedic surgery still affect the postoperative healing and return to health of patients. The most common complications in orthopedics include delayed healing, osteoporosis, and bone infection. It is well known that antibiotics are the key to the prevention and treatment of infection. However, systemic administration of antibiotics can cause a variety of sequelae, such as superinfection, systemic allergy, and drug-resistant bacteria. For this reason, local drug delivery with a higher drug concentration where the drugs are needed is the key to avoiding systemic drug side effects and achieving therapeutic effects. Fuchs et al. (2008) mixed bioactive substances into bioabsorbable poly(D-lactide) (PDLLA), which could be applied to the surface of metal fixtures by a "cold" coating process. This could be used not only as a bone material, but also as a drug carrier. Ideal results had been achieved in animal and clinical experiments using this method. Bioabsorbable polymers can be used as drug carriers to apply coating technology to various implants, which not only does not affect the mechanical stability of each implant, but also can increase the local drug concentration of the body to promote wound repair, reduce the incidence of sequelae, and avoid systemic drug effects. In addition, because all kinds of implants with different materials can be coated, this treatment idea will also be widely used clinically.

12.3.2.2 A novel bioabsorbable drug-eluting scaffold

In recent years, due to the changes in the social environment, dietary structure, and living habits, the incidence of coronary heart disease has also increased annually. Percutaneous coronary drug-eluting stent (DES) implantation has become a major breakthrough in the interventional treatment of heart disease (Zhang et al., 2020). Postoperative sequelae such as in-stent restenosis and in-stent thrombosis are important factors influencing postoperative death. In order to overcome these difficulties, the emergence of first- and second-generation drug-eluting stents has greatly reduced the incidence of stent restenosis and subsequent vascular remodeling. Despite the updating of implants and surgical techniques, in-stent thrombosis cannot be completely avoided (Kuramitsu et al., 2021). The polymer is made from two trimer molecules of salicylic acid using oxalic acid as a connecting molecule. In the process of being absorbed, the polymer releases salicylic acid, which acts on the surrounding vascular parietal cells. As a nonsteroidal antiinflammatory drug, salicylic acid can not only reduce the

inflammatory response of the stent to vascular wall stimulation, but also, as a bioabsorbable material, there is no need for concerns about the permanent retention of the implant after implantation. It may also help to prevent late complications of drug-eluting stents.

12.3.3 Application in tissue engineering

Tissue engineering is an interdisciplinary field, which mainly involves materials science, biology, reactor engineering, and clinical research. Its purpose is to cultivate or create new tissues or organs (Lavik and Langer, 2004), then transplant this tissue or organ into the body, replacing the tissue or organ in the original pathological state. These are a kind of artificially obtained tissues and organs, which can reduce mismatching between the recipient and the donor to a certain extent. After years of development, the technology of in vitro cell culture has gradually matured, but it remains a difficult problem to make cells arrange correctly into typed tissues and organs, although the emergence of 3D printing brings a solution to this problem (Zhu et al., 2016). In order for cells to grow according to certain rules, bioabsorbable polymers play a very important role. During cell culture, the cells are attached to a bioabsorbable polymer, and then the polymer cell scaffold is implanted into the body (Langer and Vacanti, 2016). This enables the implant not only to have the shape that is required, but also to perform some biological functions of the cells attached to it.

12.3.3.1 Application in bone tissue engineering

The emergence of bioresorbable polymers has triggered the exploration of bone tissue engineering (Wubneh et al., 2018), which provides scaffolds for cell growth and plays a very important role in cell localization and tissue regeneration. The biocompatibility and controllable absorptivity of polymers are also critical. Its surface should not only allow cells to complete biological activities such as adhesion, proliferation, and differentiation, but also must be able to transmit mechanical signals and have suitable mechanical strength (Vieira et al., 2017).

Natural bioabsorbable polymer chitosan meets these requirements. Chitosan is a kind of linear polysaccharide, which is commonly found in crustacean shells, insect bones, and fungal cell walls. It is widely used in biomedicine because of its unique biological characteristics. The positive charge on the chitosan skeleton makes it have hemostatic activity, it can produce an analgesic effect inflamed sites, and also has an antiinfection property. Therefore, it is

usually used as a wound coating or for artificial skin. In recent years, a large number of studies have shown that chitosan can promote cell adhesion, proliferation, osteoblast differentiation, and mineralization (Ho et al., 2014; Brun et al., 2021). Hu et al. (2021) also cross-linked chitosan, vanillin, and bioglass particles to form a new scaffold, namely chitosan—vanillin—bioglass (CVB) scaffold. After a series of in vivo and in vitro experiments, they found that this new scaffold could not only promote cell proliferation and differentiation, and mineralization into bone, it also had significant mechanical strength and antibacterial properties.

12.3.3.2 Application in ligament/tendon tissue engineering

Ligaments and tendons are a kind of fibrous tissue with only a small number of blood vessels, and their regeneration ability is poor (Nau and Teuschl, 2015). At present, the treatment of ligament or tendon injury is usually autologous or allogeneic transplantation, which may be accompanied by adverse outcomes such as infection, disease transmission, and immune rejection by the host (Cooper et al., 2005; Leong et al., 2014). These have a significant impact on the health and economy of patients, which has promoted the search for substitutes.

Natural bioabsorbable polymers such as collagen, fibrin, and cellulose have good biocompatibility and are good substitutes for extracellular matrix, which can be hydrolyzed into normal metabolic small molecules in vivo, and so it is a scaffold material often considered in tissue engineering. Collagen, as the main component of ligament, has become the first selected material for ligament tissue engineering (Leong et al., 2014; Yilgor et al., 2012). Dunn et al. (1995) seeded rabbit fibroblasts on bioabsorbable fiber scaffolds to produce ligament analogs similar to normal ligaments in vitro and verified their feasibility in vivo.

Artificial bioabsorbable polymers are easy to process and widely available biomaterials, and are used often in tissue engineering scaffolds of tendons and ligaments (Goh and Sahoo, 2010). Compared with natural bioabsorbable polymers, artificial bioabsorbable polymers are widely used, and the physical or chemical properties of polymers can be controlled by means of chemical modification (Rodrigues et al., 2013). Araque-Monrós et al. (2020) developed a ligament/tendon tissue engineering scaffold using artificial bioabsorbable materials. This kind of scaffold is a hollow reticular structure woven with polylactic acid, with microspheres containing cells in the middle, so as to regenerate tissue from the inside to the outside and replace the original aging or diseased tissue.

12.4 Conclusion

This chapter mainly describes the application prospects of bioabsorbable polymers as implants in nonpermanent implantation, as a drug-delivery device, and as a scaffold material for tissue engineering. The biomaterials used are divided into natural and artificial bioabsorbable polymers. Bioabsorbable polymer materials from different sources have different properties. Natural bioabsorbable polymers are more popular as implants because of their better biocompatibility and lower toxicity, especially plant-derived bioabsorbable polymers because of their wide availability, easy extraction, low cost, and the absence of ethical issues. Through the in-depth understanding of the physical and chemical properties of different bioabsorbable polymers, the properties of bioabsorbable polymers can be changed by chemical modification or compounding of different materials, so that bioabsorbable polymers can not only have wider application areas, they also can be more in line with the expected results of their use. Although bioabsorbable polymers have been widely studied as implants, there remain few clinical applications, and therefore more in-depth investigations are needed.

CHAPTER 13

Polymeric (PLGA-based) nanocomposites for application in drug delivery: Current state of the art and forthcoming perspectives

Sanket Kumar[1], Supriya Singh[1], Sheikh Shahnawaz Quadir[1], Garima Joshi[1], Mangilal Chouhan[1], Dinesh Puri[2] and Deepak Choudhary[1]

[1]Department of Pharmaceutical Sciences, Mohanlal Sukhadia University, Udaipur, Rajasthan, India; [2]School of Pharmacy, Graphic Era Hill University, Dehradun, Uttarakhand, India

13.1 Introduction

The development of nanocomposite biomaterials with tailored compatibility, bioabsorbability, and degradation behavior has been mostly investigated and researched over the past few decades for human health applications. FDA/EMA (European Medicines Agency)-approved PLGA (polylactic-co-glycolic acid) has drawn the most focus for clinical uses (Nair and Laurencin, 2007; Makadia and Siegel, 2011). PLGA is a PLA (polylactic acid)-based copolymer obtained most efficiently by ring-opening copolymerization of poly-lactide monomer (PLA) and polyglycolic acid (PGA) nowadays resulting in high-molecular-weight PLA-based copolymers. PLGA is an abbreviation for poly D,L-lactic-co-glycolic acid in which the D/L-lactic acid forms are in the same ratio (Dechy et al., 2004; Sharma et al., 2016) (Fig. 13.1).

PLA is a linear aliphatic polyester obtained from corn, sugar, potatoes, and other agricultural renewable resources (Nampoothiri et al., 2010) and is of three kinds based on their microstructure, PDLA is poly(D-lactic acid), PLLA is poly(L-lactic acid), and PDLLA is a racemic blend of both D-PLA and L-PLA [poly-(D,L-lactic acid)] in monophasic structure (Swider et al., 2018). Each kind PLA has a unique structure and applications. PLA does

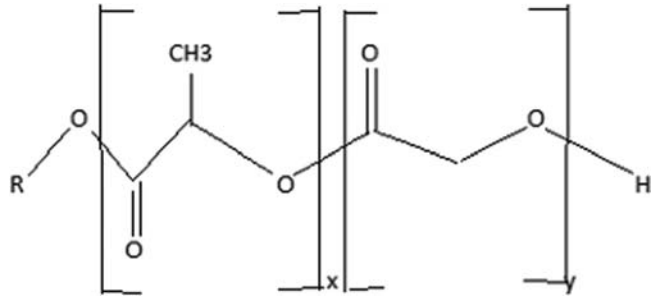

Figure 13.1 Poly-lactic-co-glycolic acid's structure (PLGA) (where *x* and *y* are number of lactic acid and number of glycolic acid units, respectively).

not cause any harm in humans as it degrades into water and carbon dioxide and can be totally cleared from the human body (Wu and Wang, 2001a). However, the most important reason for not using pure PLA instead of PLGA is due to PLA having deficient qualities, such as it is easily broken (Qi et al., 2019), has poor osteo-induction, and an unrestrained degradation rate (Go et al., 2019; Lee et al., 2016). Hence, PLA copolymer-based nanocomposites are mostly investigated as these nanocomposites meet all the requirements to improve cell adhesion and the ratio of cell propagation superficially on materials as per the current state of the art (Tang et al., 2013). These PLA copolymer-based nanocomposites are in nanometer sizes and act as a matrix in nanofillers with great potential uses in repairing and substituting synthesized bone (Sokolova et al., 2020), engineering of tissues (Davies et al., 2008), and importantly in the development of drug-delivery systems. Pinto et al. (2013) showed the effect of graphene nanosheets and graphene oxide (0.2−1 mass %) on the functional properties of poly-lactic acid films and the outcomes in yield strength, Young's modulus, and resulting nanocomposite impermeability were better than those with pristine PLA. Polymer nanocomposites such as PLA-based PLGA nanocomposites have revealed improved properties compared with pure PLA polymer (Holderegger et al., 2015).

With the help of nanotechnology, PLGA nanocomposites are greatly increasing the applications of PLA materials by providing suitable biocompatibility, as delivery vehicles for drugs, proteins, DNA, RNA, vaccines, peptides, and metallic as well as magnetic nanoparticles, and also have uses in tissue engineering and other functional properties (Mundargi et al., 2008a; Hans and Lowman, 2002; Allison, 2008). PLGA nanocomposites are physically strong and popular biodegradable polymers owing

to their long durability in clinical research and experience, showing promising degradation features and maintaining sustained drug release by implantation without the requirement for a surgical operation (Martou and Antonyshyn, 2011). The overall physical characteristics of PLGA nanocomposites are tunable by controlling the molecular weight of polymer, the lactide-to-glycolide ratio (Maquet et al., 2003), and when making the polymer–drug matrix by altering the drug concentration, which also helps in creating the desired dosage-release interval profile which depends on the type of drug (Mohamed and van der Walle, 2008). The present study shows the major applicability and forthcoming practices of PLGA nanocomposites in facilitating drug-delivery applications.

PLGA are commercially accessible in diverse molecular weights and copolymer ratios, and can be scaled into any shape and size with enhanced water solubility and tunable drug release dose-dependent profiles (Danhier et al., 2012; Lü et al., 2009). They have nonlinear biodistribution and pharmacokinetics profile (Panagi et al., 2001) and are obtained in an atactic configuration in which no regular stereochemical configuration is found in repeating units showing mutable stereochemical configurations (Cheng et al., 2007a). The PLGA degradation rate depends on the unit sequence of PLGA as random units degrade faster than sequenced units (Grizzi et al., 1995).

PLGA copolymer degrades via hydrolysis or biodegradation through the cleavage of its ester-linked backbone into oligomers, then monomers. This has been shown in vivo and in vitro for a variety of drugs and proteins with varying polymer ratios (Schliecker et al., 2003; Witt, 2001). These polymers degrade mainly by the matrix's consistent bulk degradation where water penetrating into the matrix is greater than the rate of polymer degradation. Furthermore, the process is autocatalyzed by an increase in carboxylic end-groups caused by biodegradation. Degradation of PLGA copolymer is a multistep process that includes both bulk/surface diffusion and erosion (Holy, 1999; Anderson and Shive, 1997).

PLGA has potential to encapsulate therapeutic agents such as antiseptics, antiinflammatories, and antioxidants, and can target drugs in form of the gels or micro/nano-particles (Mundargi et al., 2008b; Ding and Zhu, 2018; Arvizo et al., 2012).

The use of PLGA nanocomposites of with inorganic nanoparticles has the potential to reduce toxicity and extend PLGA's clinical applications. In recent years, researchers have thoroughly investigated the applications of PLGA-based nanocomposite materials in cancer therapy, diagnosis,

imaging, protein delivery, and gene therapy (Rezwan et al., 2006; Sun et al., 2008; Zare et al., 2019). As is discussed in this chapter, PLGA nanocomposites have also been investigated for vaccine delivery to the brain and CNS, treatment of inflammatory diseases, and scaffolds for tissue engineering (Wu and Wang, 2001b). Nonetheless, investigational efforts into PLGA nanocomposite development and marketability are still required for biomedical applications because of several issues related to scale-up, such as poor drug loading, high burst release, and production costs (Mir et al., 2017). This chapter aims to investigate recent advancements in this field, beginning with a brief analysis of PLGA properties, PLGA-based approved medicines, and an overview of the primary production methods of PLGA magnetic/nanoparticles.

13.2 PLGA properties (Martin and Averous, 2001; Nijenhuis et al., 1996; Tsuji et al., 2000; Passerini and Craig, 2001)

There are multiple factors on which PLGA's physical characteristics are dependent, such as the initial molecular weight, the lactide-to-glycolide ratio, device size, water exposure, and temperature of storage. In Table 13.1, PLGA physiochemical and biological properties and their description and parameters on which they influenced are discussed.

13.2.1 Copolymers of PLGA

The necessity for developing various types of block copolymers of polyesters with polyethylene glycol is based on their better delivery formulations that encapsulate a variety of drugs and methods of administration. Both triblock ABA (PLGA/PEG/PLGA) and BAB (PEG/PLGA/PEG) types of copolymers have been processed with diblock (PLGA/PEG) types in which PEG chains facing toward the outer hydrophilic phase in micelles are surrounded by encapsulated drug(s) (Allahyari and Mohit, 2016). The composition of PLA:PGA in a ratio of 1:1, as in PLGA 50:50, is mostly used in nanotechnology and a variety of PLGA forms can be obtained by changing the PLA:PGA ratio during polymerization (Kissel et al., 2002; Choi and Park, 2002).

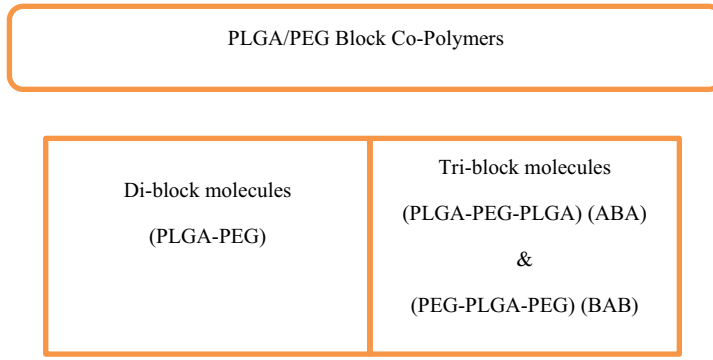

Table 13.1 Physiochemical and biological properties of PLGA polymers.

S. No.	Properties	Description	Influences on
1.	PLGA formation	Ester-linked LA and GA unit's ring-opening catalyzed copolymerization	Biodegradability
2.	Metabolism	Nontoxic byproducts, such as water and carbon dioxide yielding via Krebs cycle	Biodegradability
3.	PLGA hydrolysis	With time, there are considerable changes in the formulation and various descriptions have been provided	Copolymerization of crystalline poly-glycolic acid with poly-lactic acid results in reduced PLGA degree of crystallinity, glass transition temperature (T_g), moisture content, and molecular weight
4.	Glass transition temperature (T_g)	Glassy appearance at 37°C	In copolymer composition, T_g decreases with a decrease in lactide content and molecular weight
5.	PLGA's melting point and degree of crystallinity	—	Molecular weight, mechanical strength, behavior of swelling, hydrolysis capacity, and polymer biodegradation rate
6.	Mechanical strength	—	Molecular weight and poly-dispersity index

Continued

Table 13.1 Physiochemical and biological properties of PLGA polymers.—cont'd

S. No.	Properties	Description	Influences on
7.	Shape and size	Encapsulating almost any size of molecule	—
8.	Copolymers	Copolymers with higher PLA are less hydrophilic in nature	By absorbing less water, the degradation period is longer
9.	Solubility	Soluble	Soluble in chloroform, acetone, ethyl acetate, and tetrahydrofuran (THF)
10.	PLGA copolymers	Diblock or triblock copolymer conformations	PLGA-PEG, PLGA-PEG-PLGA or PEG-PLGA-PEG
11.	PLGA bio-distribution and pharmacokinetics	Nonlinearity and dose-dependent profile	Carrier degradation is carried out in the initial stage with around 30% and clear-out by respiration in the lungs eventually
12.	Clearance	From blood uptake by the mononuclear phagocyte system (MPS)	Depends on drug dose and PLGA carriers' composition with systems

Release of encapsulated drug(s) and proteins from copolymers is done through two mechanisms (Uhrich et al., 1999):

(i) Initial release phase: Hydrogel diffuses the drug

(ii) Later phase: Hydrogel matrix erosion facilitates drug release

By reducing collaboration with external molecules through steric and hydration repulsion, this layer of PEG serves as a barrier and improves shelf stability. With effective fabrication, the further addition of PEG leads to a reduction in drug effectiveness and encapsulating proteins (Frank et al., 2005). A lower drug incorporation may be caused by the PEG chains' steric interference with the drug/protein−polymer interaction. Diblock copolymer formulations have been shown to have better release kinetics than PLGA alone. There have also been reports of numerous methods for diblock nanoparticle-based targeted medication delivery (Choi et al., 2011). For developing a thermogel system of triblock of ABA and BAB; A-block and B-blocks were covalently linked by ester bond. At body temperature, these block copolymers are a highly viscous gel but they act as a free-flowing solution at low temperature.

The ABA and BAB block copolymers, which are temperature-responsive, are made up of hydrophobic PLGA segments and hydrophilic PEG segments. The hydrophobic PLGA segments create associative cross-links, while the hydrophilic PEG units remain in solution. When the temperature decreases, the hydrophilic solution results in more hydrogen bonding between water and PEG hydrophobic units and dissolution occurs (Alexis, 2005; Zolnik and Burgess, 2007). Greater loss of PEG component mass has been observed during degradation of BAB gel. Hence the hydrophobic nature of gel with a lower water content has been seen in aqueous solution. The solution-to-gel transition is caused by a decrease in hydrogen bonding and an increase in hydrophobic forces among the PLGA

segments as the temperature rises. Such thermo-responsive polymers are desirable options due to their responsive polymers and the simplicity of handling during scale-up, formulation, filtering, and filling, etc. (Meikle et al., 2016).

13.3 PLGA nanocomposite carriers: fabrication techniques

Since 1989, many PLGA materials have already been commercialized. PLGA nanocomposite preparation methods are still being improved by scientists to design a close-control copolymer with the desired inherent characteristics. In pharmaceuticals, drug/protein delivery is the most rapidly developing class aimed at constant or aimed delivery with lower toxicity and decreased treatment-associated risks with increased specificity. During the synthesis of PLGA particles, their physicochemical characteristics and uses can be controlled by manipulating different methods to obtain optimized products (D'Mello et al., 2006). In preparation inconsistent particle behavior may be reported through grinding devices that do not allow batch-to-batch reproducibility and phase separation in case of emulsion system, extraction of solvents, and uniformity of particles when organic solvent used are not chosen carefully (Anton et al., 2008). The PLGA MP/NP (microparticles/nanoparticles) and implants are prepared by emulsification-solvent evaporation, electrospinning, salting out, nanoprecipitation, solvent diffusion—emulsification, drying spraying and extrusion, etc. techniques are commonly employed summarized in Table 13.2 (Jain, 2000; Schoubben et al., 2019).

The challenges associated with the stability and delivery of these copolymers have limited the number of marketed products available, as listed in Table 13.3.

Table 13.2 PLGA nanocomposite and implant preparation techniques, with descriptions and limitations/applications.

S. No.	Techniques	Description	Limitations/applications
1.	Emulsification–solvent evaporation (ESE) method: (Rosca et al., 2004; Bilati et al., 2005a; Yang et al., 2001; Freitas et al., 2005) ❖ Single emulsion oil-in-water (O/W) emulsification ❖ Double (multiple) emulsion method (microparticle preparation technique)	Dissolved PLGA polymer in organic vehicles such as dichloromethane, $CHCl_3$, or ethyl acetate. Drugs (particle size around 20–30 μm), imaging probes and NPs if loaded, also codissolved in the organic vehicles. Then emulsified with surfactants (for example PVA) with continuous stirring. Then evaporate the organic phase with stirring at a suitable temperature or by reducing pressure. Multi-wash the outcome particles (such as injectable microparticle formulation) to remove polymer/surfactant residue and freeze-dry in storage for long-term use **Double emulsion method**: Generally drugs or materials to be encapsulated are emulsified with PLGA organic phase under vigorous stirring to produce primary water-in-oil emulsion. This is added to surfactant aqueous solution with continuous stirring. At a suitable temperature, evaporate the organic phase by stirring or by reducing the pressure	For intended hydrophobic loading of particles, single emulsion (O/W) emulsification method is used, e.g., steroids. Oil-in-oil emulsion is used for loading of drugs which are water insoluble. This method has a very limited % of encapsulation of hydrophilic compounds W/O/W emulsion by double emulsion method Hao et al. synthesized PLGA NPs loaded with docetaxel (DTX) adapted with poly-ethyleneimine (PEI) and gold shell NPs with targeting glioma peptide angiopep-2 (ANG/GS/PLGA/DTX NPS) (Hao et al., 2015)

Continued

Table 13.2 PLGA nanocomposite and implant preparation techniques, with descriptions and limitations/applications.—cont'd

S. No.	Techniques	Description	Limitations/applications
2.	Salting-out method (nanoparticle preparation technique)	The compounds to be loaded and water-miscible organic solvent of PLGA solution are mixed to an aqueous phase with a salting-out agent such as chloride salt of calcium and as a stabilizer polyvinyl alcohol under continuous stirring. Formation of oil-in-water emulsion takes place, and then excess water is added to the emulsion for complete diffusion of organic solvent into the aqueous phase. This results in the formation of PLGA matrix particles with loaded compounds. By filtration, the salting-out agent and stabilizer are removed with washing of the particles (Reis et al., 2006)	Best suited method to encapsulate thermosensitive materials and when a high concentration of PLGA is required (Leroux et al., 1996)
3.	Emulsification—solvent diffusion (ESD) method	To achieve thermodynamic equilibrium at room temperature, mutually saturate the organic solvent and water. In organic solvent dissolve polymer and then emulsify the aqueous solution containing a stabilizer such as PVA in a high-speed homogenizer (Esmaeili et al., 2007) After complete homogenization, water is incorporated into the oil-in-water emulsion with regular stirring; this facilitates the solvent to diffuse out	Principally prepared by Quintanar-Guerrero et al. (Quintanar-Guerrero et al., 1998) Advanced form of salting-out method High reproducibility and high % encapsulation efficiency of hydrophobic drugs Takahashi et al. settled Ag-decorated PLGA NPs of 300 nm size (Takahashi et al., 2017)

		from the internal phase. Nano-precipitation of PLGA polymer leads to the production of colloid particles. By evaporation or steam distillation (vacuum applied), remove excess solvent (Murakami et al., 1999)	
4.	Nano-precipitation method	The polymer and encapsulating compounds are liquefied in acetone/ethanol or acetonitrile. The resultant solution is added drop-wise to surfactant or emulsifier aqueous solution. Diffusion of the organic phase takes place and formation of PLGA NPs is immediate. Excess solvent is removed by reducing the pressure (Bilati et al., 2005b)	Also called the solvent displacement method Simply entrap hydrophobic drugs in a single-step process with high reproducibility in PLGA NPs (Morales-Cruz et al., 2012) A two-step method reported to have high encapsulation efficiency of PLGA NPs, proteins, and enzymes (Miladi et al., 2016)
5.	Spray-drying method (Arpagaus, 2019; Gavini et al., 2004; Nie et al., 2008)	PLGA particle formation is done when PLGA emulsion of water-in-oil is sprayed into a jet of heated air in a spray dryer Compounds to be loaded as in a W/O dispersion with PLGA polymer may affect the choice of solvent due to their hydrophobicity	Rapid and suitable method for mass production of PLGA particles and to encapsulate all varieties of drugs/proteins/peptides into microparticles A major drawback is loss in resultant total weight of particles due to spray dryer inner wall adherence

Continued

Table 13.2 PLGA nanocomposite and implant preparation techniques, with descriptions and limitations/applications.—cont'd

S. No.	Techniques	Description	Limitations/applications
6.	Electro-spinning method	With application of a high electric voltage by syringe injecting PLGA aqueous solution through a needle. The unstabilized needle then produces nanofibers with jet spinning. These nanofibers are collected in a conducting substrate. By controlling the voltage, the type of collector used, and injection rate, the diameter of these nanofibers can be fixed (Yang et al., 2005)	Method is more versatile, simpler, and low cost Mostly utilized in tissue engineering scaffold fabrication (Yang et al., 2005) Usually produces nanofibers ranging from nanometers to several micrometers A flexible nanocomposite with cotton-wool-like appearance has been successfully prepared by Schneider et al. (Schneider et al., 2011)
7.	Phase separation (coacervation) technique (Wang et al., 2011; Otsuka et al., 2003; Kumari et al., 2010; Thomasin et al., 1998)	Both the coacervate phase of polymer and the supernatant phase are washed-out in polymer. Then drug is dispersed/dissolved in solution of polymer which is coacervate-coated In polymer—drug solvent phase, gradual addition of organic medium with stirring. After this, extracts of the polymer solvent result in soft drug coacervate droplets by phase separation of polymer. Then the prepared soft coacervate is quickly dipped into	With the technique of liquid—liquid phase separation, this method is best for the fabrication of biodegradable encapsulated polymer preparations in micrometer scale Steroids (Thomasin et al., 1998) (hydrophobic drug) are solubilized or distributed in the polymer—drug solvent phase (oil-in-water emulsion) whereas peptides and proteins (hydrophilic

		insoluble solvent for quenching of these microdroplets. In the quenching bath, the soaking time controls the hardness/coarsening of the droplets. Finally, microspheres are collected via water wash, straining, filtering, and centrifugation or lyophilization	drugs) are dissolved in water and distributed in the polymer solution (emulsion of water-in-oil)
8.	Solvent-casting and compression molding method (batch-to-batch operation) (implant preparation methods)	With the desired ratio, dissolve the polymer and drug in acetone then the solvent is cast at 60°C until the process of evaporation is complete resulting in a composite material of drug–polymer which is subjected to compression molding into its tunable geometry at approximately 80°C and 25,000 psi pressure until the final density of 1 g/cc is obtained (Durán et al., 2016)	It is best to fabricate a macroscopic formulation in millimeter sizing as an implant that is subcutaneous delivers the drug in the body (Hua et al., 2002) This process requires a large amount of organic solvents and takes an extended time for the resulting material to have complete removal of solvents
9.	Extrusion method (continuous operation) (implant preparation methods) (Widmer, 1998)	The heating of polymer–drug mixture results in a semiliquid phase using heating sources and with an extrusion screw for applying stress which pushes the mixture through the die. This is then cooled and solidified, and then cut into the required length for implants	This method is done without using solvent, the mixture of polymer–drug is drawn through a die to fabricate implants (Wang et al., 2010)

Table 13.3 FDA-approved marketed brands of PLGA MP/NPs with active principles and applications (Wang et al., 1888; Zhong et al., 2018; Garner et al., 2015; WCG, 1067).

Form/active principle	Brand	Delivery	Application	Approved year
Implant/goserelin acetate	Zoladex®	Subcutaneous	Prostate carcinoma	1989
Microparticle/leuprolide acetate	Lupron®	Intramuscular	Central precocious puberty/endometriosis	1995
Microparticle/octreotide	Sandostatin® LAR	Subcutaneous	Secreting tumors (VIP) and metastatic tumors with associated severe diarrhea	1997
Nanogel/leuprolide acetate	Eligard®	Subcutaneous	Prostate cancer—advanced	2002
Microparticle/buserelin acetate	Suprecur®	Intramuscular	Endometriosis	2002
Microparticle/risperidone	Consta®	Intramuscular	Schizophrenia and bipolar disorder	2003
Implant/dexamethasone	Ozurdex®	Subcutaneous	Macular edema	2009
Microparticle/pasireotide pamoate	Signifor® LAR	Intramuscular	Acromegaly and Cushing syndrome	2014
Microparticle/triamcinolone acetonide	Zilretta®	Intraarticular	Osteoarthritis	2017
Nanoparticle/buprenorphine	Sublocade®	Subcutaneous	Moderate to severe opioid addiction	2017

13.3.1 Factors influencing the degradation of PLGA

To design a drug-delivery device with PLGA's tunable properties, it is necessary to understand the factors influencing the degradation of PLGA which makes it more efficient and effective.

Composition's effect	For tunable hydrophilicity and degradation rate, composition of the polymer is the prime factor to determine	Studies related to accelerating weight loss of polymer, enhanced glycolic acid percentage in oligomer unit. Higher hydrophilicity leads to superior degradation of glycolic acid such as PLGA in ratio of 65:35 shows less degradation than PLGA in ratio of 50:50 (PLA/PGA) and faster degradation than PLGA in ratio of 75:25 and so on with PLGA 85:15 (Park, 1995)
Crystallinity (Bouissou et al., 2006)	Crystallinity and glass transition temperature both have indirect effects on the rate of degradation. Copolymer composition effects on these properties	Degradation rate increases with enhanced crystalline characteristic of polymer such as semicrystalline PLGA polymer due to increased hydrophilicity
Molecular weight (Mw)	Molecular weight is directly related to the chain size of the polymer. With higher molecular weight, polymer degrades more slowly and requires more time for degradation than polymer with short chains	Exception is PLLA where the molecular weight is inversely proportional to the degree of crystallinity (Castelli et al., 1996; Park, 1994).
Drug type (Siegel et al., 2006)	From surface degradation to bulk erosion, the presence of	In a biodegradable polymer system, the effect of the drug's chemical properties

(*Continued*)

—cont'd

	drugs will affect both the degradation mechanism and also the matrix rate of degradation	explains the overall drug-release behaviors (Ghitman et al., 2020)
Effect of size and shape of the matrix	A higher degradation rate has been seen in polymer devices with higher surface areas	A polymer device with a higher surface-area-to-volume ratio makes the release of the drug faster. PLGA bulk degradation is faster than surface one (Grayson et al., 2005; Gallo et al., 2014).
Effect of pH	Strongly acidic and alkaline media both accelerate PLGA in vitro hydrolysis (Li and Chang, 2005)	PLGA autocatalysis in slightly acidic and neutral media is less noticeable due to carboxylic end groups
Effect of enzymes (Esmaeili et al., 2008)	There is conflicting published data on in vitro and in vivo degradation mechanism observations which cannot be closely correlated due to the effect of enzymes as both hydrolytic and enzymatic cleavage	Proposed studies showed that the hydrolytic degradation primarily degrades PLGA rather than as suggested by enzymes
Loading of drug	Polymer matrices have a high drug load owing to a greater initial burst release than those with a low amount of drug-loading matrices	Drug type decides the level of drug content which is attenuated at a certain level (Crotts and Park, 1998)
Toxicological studies	For mild toxicological reactions, PLGA is one of the safe polymers at micro/macro-scaling and also better for application at the nanoscale	Toxicological investigation with PLGA devices shows that at the application site local tissue reactions may occur (Mura et al., 2011)

13.4 Applications of PLGA nanocomposites

13.4.1 Synthetic bone substitute and repair

With the improvement in living standards over the past few decades, there has been an increase in the prevalence of various bone disorders and the frequency of traffic accidents, which has led to a growing demand for artificial bone replacements or bone repair materials. Human bones are highly susceptible to damage or loss through pathological changes, trauma, or both. Currently, the creation of materials that aid in bone regeneration and in healing bone defects chiefly focus on preclinical investigation and utility in clinical areas. Orthopedic surgeons frequently fix bone defects using artificial bone substitutes which are placed in the body, so it is vital for selection of appropriate replacements.

Outstanding biocompatibility, osteoinductive, and osteoconductive qualities are essential for a good bone substitute (Bakhshalian et al., 2014). In earlier research, nontoxic bioabsorbable polymer implants were employed extensively in orthopedic surgery, including bone replacement and fracture repair. In dental, orthopedic, and craniofacial procedures, polymer devices such as pins, plates, and screws are often employed. For the preparation of porosity scaffolds and the repair of broken bones, PLA and PLGA are two promising copolymers that have been investigated most (Jo et al., 2015).

With the purpose of reducing patient suffering, the greater degradation of PLA materials eradicates the necessity for a second operative procedure and avoids the removal of implants. Additionally, using PLA materials lowers the likelihood of operation failure, thereby reduces the stress burden of patient. Pure PLA materials do not have the same bone-bonding strength as PLA-based nanocomposites, and their regeneration efficiency and degradation behavior are not as good (Lee et al., 2019). The PLGA (PLGA/TCP60:40) was mixed with tricalcium phosphate nanoparticles in amorphous form (TCP). Through its exceptional moldability, the material's characteristically cotton-like shape can be fitted to any bone deficiency. The matrix behavior of PLGA/TCP-calvarial defects significantly enhanced the compressive mechanical strength in all nine white rabbits (New Zealand) when compared to PLGA-treated calvarial defects after 4 weeks followed by implantation grafting, the graft material resorption was also seen (Gentile et al., 2014). Calcium phosphate ceramic (hydroxyapatite: HAp) has been primarily employed as artificial bone materials in various surgical procedures due to its great biocompatibility and similarity to human

bone (Hasegawa et al., 2006). Additionally, HAp has been frequently mixed with a PLA polymer matrix, and the resulting HAp-PLLA matrix showed enhanced biotic performance. In situ polymerization of L-lactide and glycolide was successfully completed by Takeoka et al. Numerous PLGA/HAp composites with various PLA:PGA ratios in porous discs of HAp have been produced (Takeoka et al., 2015).

Bioglass 45S5 application (Lu et al., 2014) has drawn a lot of interest because it is crucial to control the rate at which the polylactic acid matrix used as the fixation for bone devices and the degradation rate can be controlled by the crystalline behavior, molecular weight, size, and shape. Numerous studies have illustrated the breakdown of polymer in the presence of bioglass resulting in primary rapid loss of weight as the bioglass dissolves (Kranz et al., 2000). The local environment eventually becomes alkaline as the bioglass salts-out when it comes into touch with bodily fluids, neutralizing lactic acid, and the rate of polymer degradation decline. In general, almost all investigations demonstrate a direct connection between bioglass and the breakdown of the polymer matrix, in other words, weight loss. The results showed that the presence of bioglass in composites significantly speeds up polymer breakdown, and a 30% bioglass content encourages osseointegration in bones within a month after implantation. After 1 month, X-ray tomography and 3D images show a white line clearly indicating the process of new bone development around the implant (Vergnol et al., 2016). All of these findings suggest that this composite, which contains 30 wt.% bioglass particles, has significant potential for use in the medical field. Although bone allograft has good osteo-conduction and osteo-induction, and also has many of the same chemical components as bone autograft, its clinical usage has been constrained by its challenging shape, poor porosity, and unfavorable degrading behavior (Dimitriou et al., 2011). In this circumstance, demineralized bone matrix (DBM) forms collagen, and the bone growth elements are beneficial for bone regeneration (Zhang et al., 2015). Demineralized bone matrix formulations are available in a variety of forms in the market, including granules, powdered, gel, putty, and paste. Porous PLA/DBM composite biomaterials were created by Zhang and Ma (1999) using the supercritical CO_2 approach, a novel preparation technology that is well suited to the processing of bioactive materials nourished with growth modulators. The X-ray result and histological analysis showed that the healing process of PLA/DBM composite to bone formation is significantly better than PLA. Finally, the authors proposed the viability of using PLA/DBM to mend bone

deformities. The rate of degradation, products of degradation, and bioactive mechanical characteristics are best suited for bone replacement and repair. Nano-sized tricalcium phosphate, HAp, bioactive glass, or formulations containing DBM are enhanced with PLA/PLGA qualities (Araujo et al., 2014).

13.4.2 Tissue engineering

A new field in human healthcare focuses mainly on tissue regeneration and organ development. The sustained focus on the structural, functional, and growth mechanisms of tissues in biological environments against the backdrop of science related to cell development and biological engineering advancement has created innumerable benefits. Scaffolds are used for tissue engineering, and involve bone, blood vessel, and neural system regeneration (Kim and Martin, 2006), where they work as the cell transporter for attachment and development. Cell functioning is influenced by the base environment, involving biochemical and mechanical signals, while scaffolds have tunable structural advantages for cells, enabling a number of biological functions. Hence, as PLA materials are very biocompatible, they are frequently employed as scaffolds. It has been examined on the basis of alignment that PLLA micro/nano-fibrous scaffolds for their effectiveness in brain tissue engineering (Sundback et al., 2005). The findings demonstrated that neural stem cells (NSCs) with their outgrowth neurite expand in a parallel way to PLLA fibers so that aligned scaffolds appeared to have no relationship with the rate of differentiation of cells and arrangement of fibers (Table 13.4).

Additionally, nanofibers outperformed microfibers in terms of differentiation performance, highlighting the tremendous potential of PLLA scaffolds (with nanofibers aligned) for stem cell engineering. Numerous different biomaterials, including collagen and oxide of graphene, are slowly introduced for polymerization of PLAor PLGA for the design and construction of ideal scaffolds.

The electrospinning technique prepares such scaffolds effectively with the capability for mass production enabling a greater scaffold core area.

Investigation efforts have been made for a scaffold surface with increased cell adhesion and proliferation that will change the field concept of tissue engineering. For additives such as collagen, etc. it allows an increase in the core activity in poly-lactic acid and PLGA scaffolds. In the future, technological maturation of tissue regeneration needs further experiments into

Table 13.4 Researched PLGA nanocomposites/microparticles/implants.

S. no.	Investigators	Researched PLGA nanocomposites/ microparticles/implants	Preparation technique	Field of application
1.	Shin et al. (2012)	GO was used to create hybrid fiber matrices from PLGA and collagen (GO-PLGA-Col matrices)	Electrospinning process	In tissue engineering, these hybrid candidates are best used to induce spontaneous myogenesis
2.	Ziabari et al. (2010)	Demineralized bone particles (DBPs) were used to create scaffolds of PLGA copolymer	Solvent cast method or salt leach-out method	DBP was used on a PLGA scaffold to increase the smooth muscle cell growth and gene expression
3.	Ardjomandi et al. (2015)	The topography and angularity of the produced scaffolds were examined after a succession of coatings of tricalcium phosphate scaffolds had been prepared	Dip-and-dry coating	—
4.	Shim et al. (2015)	Resorbable membrane of polycaprolactone was created shaped in a semi-domed form (PCL/PLGA-TCP)	CADD 3D printing	Using this, the problem associated with the organic solvents used in preparation of scaffolds that cause impairments to cells and tissues has been solved
5.	Davachi et al. (2016)	Nearly 30% encapsulation of triclosan was observed in a melt mix of PLLA of high molecular weight and low molecular weight		Results indicated that the use of PLA3 with 5% LAT30 was the most viable choice for bone tissue engineering, primarily because triclosan's adverse effects were lessened by its encapsulation close to the tissue environment

6.	Shafiq et al. (2015)	Star-shaped conjugates of P-(LA-co-CL) and P (SP-) copolymer were mixed in the correct ratios to create nonwoven meshes. Then, Sprague–Dawley rats were implanted subcutaneously with P-(LA-co-CL) and SP-meshes	Electro-spinning	When doing a hematoxylin and eosin staining test, it was discovered that meshes of SP and P-(LA-co-CL) had become cellularized. These cutting-edge scaffolds must be used in soft tissue regeneration
7.	Mikael et al. (2014)	Using MWCNT (inorganic) for the fabrication of functionalized PLGA-MP-based scaffolds		Engineering of bone and tissue regeneration process: both show good cellular compatibility
8.	Sheikh et al. (2015)	Hybrid PLGA with silk fibroin fabrication of scaffolds embedded with HAp NPs		Upon implantation, these scaffolds of PLGA–silk–HAp showed good swelling and water uptake capacity by which they can retain biological fluids also.
9.	Selvaraju et al. (2018)	Instead of using silk, scaffolds were prepared using collagen composite-PLGA embedded in HAp nanoparticles		Result showed that the composite acts as a scaffold, being nontoxic to cells and utilized for engineering of bone and tissue development and their translation at a clinical level

10.	Pelaseyed et al. (2020)	Scaled scaffolds as a foam base with PLGA-nanopowder of TiO_2 embedded		These scaffolds were presented for attachment of the cell, their proliferation enabled transferring nutrients with best mechanical properties and wide applicability in the regeneration of bone
11.	Haider et al. (2015)	PLGA-CuO antibacterial nanoparticles with nanofiber composite scaffolds were developed		Results reported antibacterial properties in scaffolds utilized as internal/external dressing components for wounds

the feasibility of PLGA-based composites which might be the novel future candidate for nanocomposites being used also in the neuronal and vesicular systems (Dhandayuthapani et al., 2011).

13.4.3 Drug-delivery system

An uncontrollable level of drug after administration several times a day was a major drawback which still cannot guarantee a cure with a conventional drug formulation. This burden with undesirable side effects has created opportunities for scientists to develop such a drug-delivery system that pivotally links drug therapy with the aim of retaining a sustained drug concentration in the blood while acting on the targeted area. These novel systems deliver the drug in a defined time at gradual level & evading the drug's decomposition (Yu et al., 2009) (Table 13.5).

Currently, nanocomposites made by PLGA nano/microparticles with primary characteristics of being biodegradable, biocompatible, and nontoxic, with prolonged circulation and a wide payload capacity to hold drugs, both water-soluble and water-insoluble, have been used in the healthcare market and are undergoing continued research.

The most exploited biodegradable PLGA polymers are fabricated nanocomposite formulations created through techniques such as evaporating the solvent, salting-out, displacement of solvent, and diffusion methods. The resultant carriers are excellent for encapsulation of savoxepine (psychotic drug), tyrphostins (restenosis drug), the progesterone hormone, oridonin, and BSA protein. Also, these PLG nanocomposites have been utilized in sustained-release systems for drug delivery due to their gradual degradation with an extended retention time (Tansik et al., 2014). The remaining challenge is the preparation and storage of these PLGA polymers with drugs that do not create a surrounding acidic, environmentally negative result with a negative effect on protein stability when degradation begins. Further research should be conducted to overcome the drawbacks associated with drug—PLGA polymer matrices.

13.4.4 Therapy and theranostic agents

Nanoscaled PLGA nano-inorganic, biodegradable, biocompatible, and nontoxic combinations (described in Table 13.3) have been previously employed for clinical advancements in the treatment of many conditions due to their expanded functionalities in several areas of application (described in Table 13.6).

Table 13.5 Drug-delivery systems of PLGA nanocomposites.

S. no.	Researchers	Study	Method used	Observation
1.	Tobio et al. (1998)	Discovered that polymerized PLA/TCP carriers may retain gentamicin for up to 4 weeks while releasing 60% of it in the first week	–	Numerous copolymers of PLA, as well as single polylactic acid carriers have been the subject of research
2.	Ueng et al. (2002)	Prepared PLGA polymerized nanospheres	–	Determined the optimal drug-loading of materials
3.	Govender et al. (1999)	Investigated PLGA nanoparticles with procaine HCl	Nano-precipitation	By adjusting the pH of the watery phase, switching procaine HCl for procaine dehydrate, or involving excipients in sizing, one can also modifying the efficacy of the drug delivery
4.	Khodaverdi et al. (2012)	Prepared in situ gelling matrices of thermosensitive triblock copolymers of ABA	–	Release rate of drug, copolymer concentration, and formulation microstructure by molecular weight, according to in vitro drug-release experiments. Emphasized that the system for controlled release of naltrexone-HCl and vitamin B12 is best suited to ABA copolymer in a PLA-to-PGA ratio of 5:1
5.	Lal and Datta (2015)	Recently prepared montmorillonite-PLGA (Mt-PLGA) nanocomposites scaled by using Mt-ATN units (ATN-03 and ATN-05) and PLGA	Double emulsion solvent evaporation method for water-in-oil-in-water system	Developed for the administration of atenolol (ATN) by sustained-release oral dosage

Table 13.6 PLGA-based nanocomposites used in therapy and as theranostic agents.

Author	Field of application	PLGA nano composites	Utilization
Fazio et al. (2015)	Cancer therapy	Inventor used a diblock copolymer of PEG–PLGA nanoplatform embedded with gold nanoparticles and SLB	Gold nanoparticles are able to absorb heat and this phenomenon of absorption is utilized in hyper- and photo-thermal therapy and drug delivery
Fang et al. (2015)	Cancer therapy	Synthesized microspheres of drug DOX-containing PLGA in Fe_3O_4 coating. (DOXMMS)	Results showed increased release of DOX from the microsphere after exposure to an AMF, resulting in the destruction of cancer cells. DOX-MMS treated 81.6% of viable 4T1 cells versus AMF exposure of 10% of treated viable cells
Saengruengrit et al. (2018)	Immunotherapy	Fe_3O_4/PLGA nanoparticles	PLGA nanoparticles coated with Fe_3O_4-encapsulated BSA were adopted by macrophages and dendritic cells of bone marrow after exposure to AMF
Stankovic et al. (2016)	Observed to be bacteriostatic against Gram-negative and Gram-positive bacteria and the yeast *Candida albicans*	Zn-oxide–PLGA nanoparticles and silver organic hybrid materials have been developed	Reported use of such nanoparticles in suppression of growth of microorganisms

Hao et al. (2015)	Cancer theranostics and X-ray imaging applications	PLGA nanoparticles designed with PEI involving Au-nanoshells and angiopep-2 with DTX	DTX-loaded PLGA@Au nanocomposites
Song et al. (2012)	PA image-guided photothermal therapy as favorable agents for translation at clinical level for forthcoming image-based cancer therapy	Proposed AuNRs—PLGA conjugation with gold	AuNRs@PEG/PLGA nanocomposites

13.4.5 Applications of PLGA composites with core–plasmonic NPs

Several representative studies offering dissimilar groupings of PLGA and plasmonic NPs, available in customized micro-, nano-, and macroscopic assemblies are discussed here (Table 13.7).

13.4.6 Applications of PLGA-nano/magnetic nanocomposites

Recent decades have seen the development of customized magnetic NPs (MNPs), which exhibit a specific reaction for use in the applied magnetics field. Magnetized nanoparticles have been employed as agents for various MRI applications since the 1990s (De Moura et al., 2020) (Table 13.8). Magnetic nanoparticles have been utilized to produce energy in the AMFs field, which is advantageous for controlled delivery in medicines as well as being applicable for reducing malignancies by magnetized hyperthermia (Vieira Rocha et al., 2020). Some MNPs also exhibit sensitivity patterns to influence acidic and basic environments and oxidation–reduction conditions.

Due to their applicable magnetic-physiochemical properties and simplicity of development, as seen in FeO nanoparticles, also called SPIONs, are mostly utilized in scaling of medicines at nano-level (Ribeiro et al., 2021; Zhang et al., 2011). They are comprised under 20 nm diameters crucially with supermagnetized involving all magnetic characteristics inside of it. In order to develop functional nanocomposites as therapeutic utility in diagnosis through MRI/PA (Zhang et al., 2020), a number of techniques have been devised to embed magnetized nanoparticles in PLGA NPs/MPs form.

13.4.7 Applications of other PLGA/inorganic-NP-based composites

Combinational PLGA polymeric composites have been used with inorganic nanoparticles such as Zn, Ce, C, Cu, and Ti but most medical applications are with HAps. PLGA–inorganic nanoparticulate composites when scaled-up using ZnO additionally provide optical, semiconductive, and catalytic features of inorganic Zn, and as a biocomposite it is biochemically stable, nontoxic, and medically used against microbes and both Gram-positive and Gream-negative bacteria (Lanao et al., 2013; Houchin and Topp, 2009; Cheng et al., 2007b; Tang and Dong, 2009) (Table 13.9).

Another targeted inorganic–PLGA composite is nanoceria (CeO_2-NPs), which scavenges ROS to regenerate the oxidative state under severe

Table 13.7 Applications of dDifferent PLGA—-Pplasmonic NPs in researched.

Investigator	PLGA—plasmonics	Size of nanocomposites	Method of preparation	Applications
Hao et al. (2015)	Reported synthesis of PLGA-loaded modified docetaxel with polyethyleneimine with a covering of gold nanoparticles in the presence of angiopep-2 which is a targeting peptide in glioma	Approx. 200 nm	Improved emulsification solvent evaporation method	As chemophotothermal agents for DTX + PTT drug detection; as an agent for X-ray imaging in the treatment of tumors
Song et al. (2012)	Developed plasmonic composite PLGA vesicles where gold nanorods (AuNRs) were embedded in the vesicle shell formed by PLGA, with PEG molecules extending to the interior and exterior of the vesicle, providing stability (PLGA/AuNRs)	Approx. 60 nm in size	Emulsification solvent evaporation method	Nanocomposites were used as theranostic agents
Topete et al. (2014)	Scaled PLGA nanocomposite embedded with DTX (doxorubicin) as an anticancer agent consistently covered with a porous-shell (BGNSH) which was activated by HAS-ISG and complex folic acid	125 nm approx. size	Nano-precipitation method	Reported composite used for extended-release pattern mapping and also in optical image contrasting by fluorescence characteristics

Table 13.9 Inorganic nanoparticle-based PLGA nanocomposites with the method of preparation and applications.—cont'd

Investigator	Preparation of PLGA composites	Method	Resultant size	Applications
Li et al. (2001)	Finalized nanocomposite core–shell with PLGA-embedded silver/gold nanoparticles (PLGA@Ag/AuNPs)	Stabilizer-free technique	Spherical shaped, nearly 200 nm	SERS, enhanced signaling in surface-enhanced Raman spectroscopy analysis by nanoshell particles
Pelaseyed et al. (2020)	Developed scaffolds in different ratios of commercialized nano-PLGA-TiO_2 nanoparticles	Resultant microporous design developed by a process of air–liquid foaming in which bubbles of gas were created using nucleation	–	These scaffolds were best for regenerated bone engineering
Sheikh et al. (2015)	Scaffolds prepared using composites with hybridization of PLGA-fibroin silk-HAp scaffolds	–	180–250 mm	Regenerative engineering
Selvaraju et al. (2018)	Processed PLGA-collagen with inorganic HAp nanoparticles	–	Modified chemical precipitation method	HAp facilitates PLGA composite's physicochemical properties and stability for molding into porous scaffolds applied for bone and tissue regeneration

Haider et al. (2015)	Developed scaffolds of PLGA hybrid fiber in nano-sizing, comprises CuO-NPs	Electrospinning method	Mean span was 550 nm	Investigated CuO-NPs for antibacterial activity
Wang et al. (2017)	Prepared double-coated PLGA nanoparticles (primary coat of CTAB with secondary coat of manganese dioxide nanofilm at ultrascale) embedded with DTX-AuNRs (PLGA-AuNRs/DTX@MnO_2 NPs)	Simple ESE method	Mean size of 280 nm	Proposed application of nanocomposites in MRI-dual modeling, diagnosis for Mn and Au detection by CT X-ray and utilities as theranostic and diagnostically in RF-induced hyperthermia chemotherapy

biological conditions with reusable antioxidative activity which reduces the activity of the superoxide dismutase and initiates both superoxide radicals and hydrogen peroxide's conversion with the resultant availability of water and oxygen (Luo et al., 2019).

PLGA-CNT scaffolds have been scaled due to their enhanced surface area, low density, and higher mechanical integration. Nanomaterials developed as CNTs make ideal scaffolds such as CuO nanoparticles providing greater research benefits optically, electrically, and medicinally due to Cu^{2+} ions in metal form (Kuang et al., 2016). The scaffolds design are used as nanoscale medicine as antimicrobial by releasing of copper ions (Ahamed et al., 2014).

Engineering for bone implant fabrication with resultant tunable biocompatibility and superior mechanical properties has resulted in the use of titanium dioxide (TiO_2) in scaffold fabrication for bone implants enabling excellent physical and biological properties, for example resistance due to corrosion, reduced weight, nontoxicity, and increased cell proliferation and adhesion (Chen et al., 2016a).

The most important naturally bioactive and powerful are inorganic HAp NPs, the nanostructure of which is extensively utilized in combination with PLGA as a component for the fabrication of bone scaffolds with greater biocompatibility, decreased immunogenicity, etc. (Furukawa et al., 2000).

13.5 Conclusions and future prospects

At both the industrial and research scales, PLGA composites have been created for biomedical applications. The varieties of inorganic hybrid nanoparticles/composites based on PLGA in the present study show the adaptability of this family of materials, which spans the nano, micro, and macro ranges. The physicochemical characteristics, biocompatibility, shape, and multi-functionality of these PLGA hybrids have demonstrated their importance. The majority of the discussed hybrid materials have easy-to-follow synthesis methods, which gives them significant benefits over other types because the follow-up scaling can be quickly modified for a range of applications. In general, increased hydrophilicity, chemical collaboration between the hydrolytic functional groups, and decreased crystalline behaviors of the materials can speed up PLGA degradation and release of drug(s). To adjust drug release and degradation mechanisms for the desired application, all of these parameters should be strictly monitored and

considered. Hence it is advised to customize the amorphous polymer(s) with increased hydrophilicity for short-term release requirements of up to a month.

Numerous studies have shown that PLGA can be simply formulated as a drug-transporting device at all scales as micro/nano-spheres, and even as implants of millimeter size. PLGA can be used in a variety of drugs, peptides, and proteins, and can be transported over different ranges within a specified timeframe using a variety of delivery routes.

The final uses of PLGA are frequently determined by the inorganic components that will be mixed with it, as well as by the organic therapeutic agents such as drugs, proteins, peptides, vaccines, and DNA loaded on the PLGA platform. To avoid the uncomfortable surgical insertion of implants, PLGA particles such as micro/nanospheres and micro/nanocapsules can be used for controlled delivery as injectable, biodegradable, and biocompatible forms. PLGA composites are simple to produce, made in a variety of shape and sizes, with biocompatibility, drug compatibility, acceptable biodegradation kinetics, and superior mechanical qualities.

Multiple applications can be combined using multifunctional PLGA-based composite materials to improve diagnostic and therapeutic outcomes. A significant advancement in the field of biomedicine, PLGA materials and nanocomposites hold considerable potential for future advancements in the tissues engineering, therapeutics, theranostic, and diagnostic fields.

Abbreviations

%EE	% Encapsulation efficiency
AgNPs	Silver nanoparticles
AMF	Altering magnetic field
AuNPs	Gold nanoparticles
AuNRs	Gold nanorods
BPLP	Biodegradable photoluminescent polyester
CAs	Contrast agents
CNPs	Cerium oxide nanoparticles
CNTs	Carbon nanotubes
CTAB	Cetyl-trimethyl-ammonium bromide
DCM	Dichloromethane
DOX	Doxorubicin
DTX	Docetaxel
EMA	European Medicines Agency
ESD	Emulsification solvent diffusion

ESE	Emulsification solvent evaporation
FDA	U.S. Food & Drug Administration
GSH	Glutathione
HAp	Hydroxyapatite
HIFU	High-intensity focused ultrasound
INPs	Inorganic nanoparticles
MRI	Magnetic resonance imaging
MWCNTs	Multiwalled carbon nanotubes
PDT	Photodynamic therapy
PLGA	Poly-lactic-co-glycolic acid
PTT	Photothermal therapy
SOD	Superoxide dismutase
SPIONs	Superparamagnetic iron oxide nanoparticles
SPR	Surface plasmon resonance
W/O/W	Water-in-oil-in-water

Conflicts of interest

The authors declare that there is no conflict of interest regarding the publication of this chapter.

CHAPTER 14

Bioresorbable polymers: Challenges and opportunities for development and applications of medical devices

Pornnapa Kasemsiri[1], Kaewta Jetsrisuparb[1], Jesper T.N. Knijnenburg[2] and Manunya Okhawilai[3]

[1]Sustainable Infrastructure Research and Development Center and Department of Chemical Engineering, Faculty of Engineering, Khon Kaen University, Khon Kaen, Thailand; [2]Biodiversity and Environmental Management Division, International College, Khon Kaen University, Khon Kaen, Thailand; [3]Metallurgy and Materials Science Research Institute, Chulalongkorn University, Bangkok, Thailand

14.1 Introduction

Bioresorbable polymers are designed to have retentive properties during their shelf life and can be degraded over time by dissolving directly and slowly in body fluids. In the degradation process, bioresorbable polymers are metabolized or degraded via urinary excretion or the citric acid cycle without any risk associated with foreign body reactions (Low et al., 2020; Ramakrishna et al., 2001). Examples are the degradation of poly(glycolic acid) (PGA) and poly(lactic acid) (PLA) (Fig. 14.1). The hydrolytic cleavage of PGA and PLA produces glycolic acid (GA) and lactic acid (LA), respectively. Some of the produced GA is then transformed into oxalic acid and excreted via urine. Another part of the GA is further converted into glyoxylate and subsequently into glycine via glycine transaminase. The glycerin is transformed into pyruvic acid and finally converted to CO_2 and water in the citric acid cycle (On et al., 2020; Pappalardo et al., 2019).

Recently, bioresorbable materials based on polymers have attracted much attention due to their wide ranges of physical, mechanical, and chemical properties. Such bioresorbable polymers are frequently also designed to have smart functions such as shape memory, controllable release, and self-healing (Maitz, 2015). To produce bioresorbable polymers for medical devices, both natural and petroleum-based polymers have been used (Park et al., 2017; Ramakrishna et al., 2001). In this chapter,

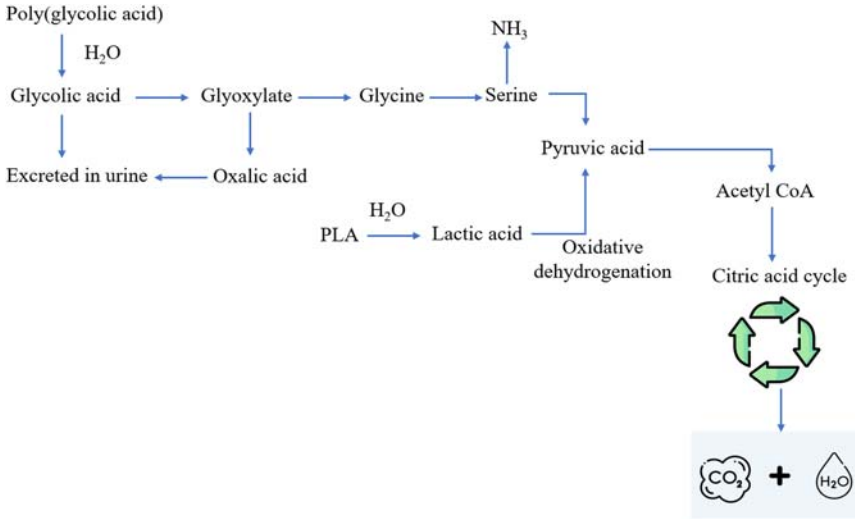

Figure 14.1 The degradation pathway of poly(glycolic acid) (PGA) and poly(lactic acid) (PLA) (On et al., 2020; Pappalardo et al., 2019).

bioresorbable polymers used in medical devices are classified into three groups according to their applications: drug delivery, medical devices, and tissue engineering, as illustrated in Fig. 14.2.

14.2 Bioresorbable polymers for drug-delivery systems

The drug release from bioresorbable polymers can occur through two mechanisms: (1) erosion, in which the polymer matrix slowly disintegrates resulting in pore formation, and (2) diffusion of drug molecules through water in the polymer matrix, driven by the osmotic pressure and differences in chemical potential (Fredenberg et al., 2011; Varde and Pack, 2004). These drug-release mechanisms are schematically depicted in Fig. 14.3.

A number of bioresorbable polymers for drug delivery have been investigated, including aliphatic polyesters (Washington et al., 2017), alginate (Srikhao et al., 2022), chitosan (Bernkop-Schnürch and Dünnhaupt, 2012), polyvinyl alcohol (PVA) (Rivera-Hernandez et al., 2021), polyamide, poly(N-isopropylacrylamide) (Gheysoori et al., 2023), and dextran (Prasher et al., 2022). The properties of the polymers are key parameters that affect drug release. For example, the molecular weight, crystallinity, and hydrophobicity/hydrophilicity influence the water absorption, hydrolysis, and erosion rate, which ultimately control the drug release (Kamaly et al., 2016; Stiepel et al., 2022). This is discussed in more detail in the following sections.

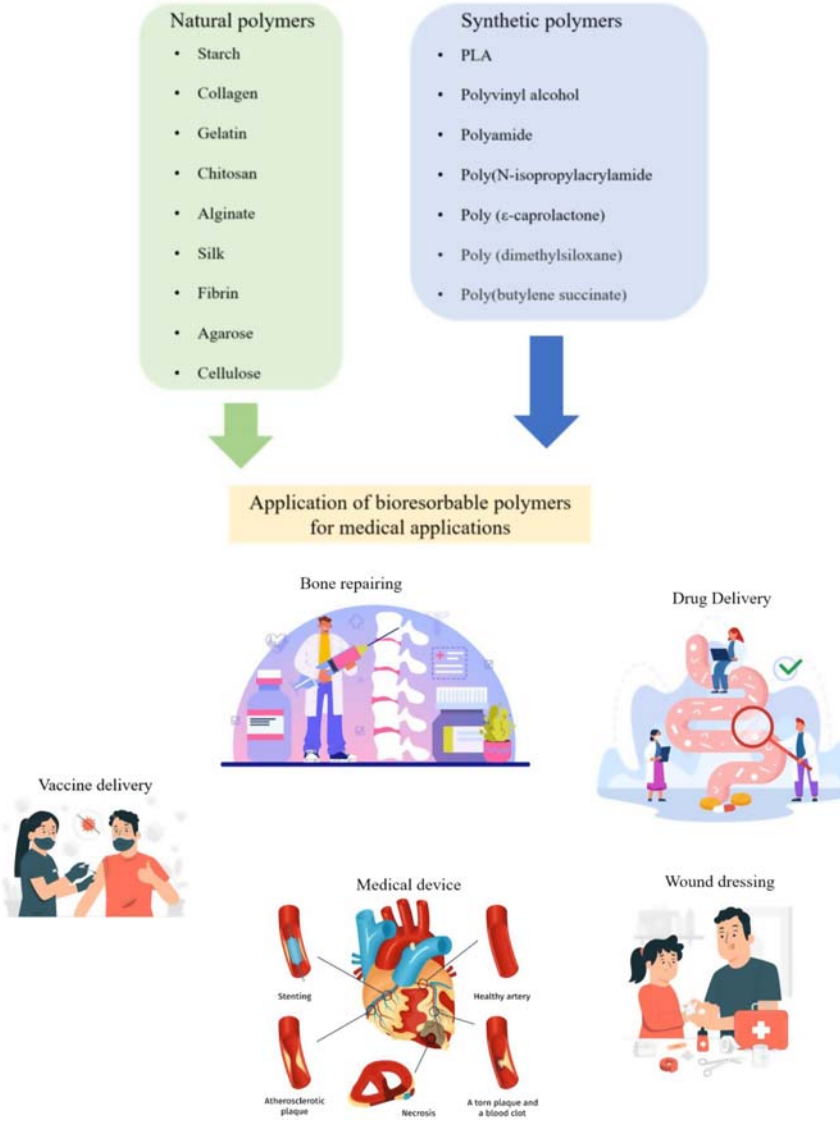

Figure 14.2 Bioresorbable polymers for medical applications.

14.2.1 Degree of crystallinity

Drug molecules are most frequently entrapped in amorphous sections of the polymer, which are more accessible to water and more permeable than the crystalline sections. Therefore, the degree of crystallinity of the polymer greatly influences the swelling and biodegradability in drug-delivery

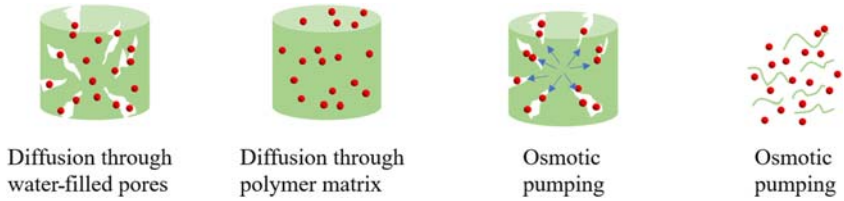

Figure 14.3 Model of drug release from bioresorbable polymers.

systems. Generally, a polymer with lower crystallinity provides a higher drug release rate (Karavelidis et al., 2011; Miles et al., 2021). Table 14.1 presents the relationship between the degree of crystallinity and the release of ropinirole. The degrees of crystallinity of poly(propylene glutarate) and poly(propylene adipate) are higher than for poly(propylene azelate) and poly(propylene pimalate), resulting in higher drug-release rates. The high crystallinity of the polymer matrix may negatively affect the drug release since the lamellar phase in the crystallized regions may hinder water penetration during drug diffusion. Furthermore, the crystallinity may also affect the mechanical properties and resorption rate, with a higher crystallinity resulting in better mechanical properties but a lower resorption rate (Tesfamariam, 2016).

In addition to the degree of crystallinity, the crystallite size is another factor that may influence drug release. Miles et al. (2021) observed more rapid drug release for larger crystallites. Smaller crystallites could increase tortuosity (and thus the path length for drug diffusion), resulting in slower drug release.

14.2.2 Hydrophobicity/hydrophilicity

The hydrophobicity and hydrophilicity of a polymer are used to design its degradability during drug release. The blending of hydrophobic and hydrophilic polymers is one approach that can control polymer degradation,

Table 14.1 Relationship between the degree of crystallinity of polyesters and ropinirole release (Karavelidis et al., 2011).

Types of polyesters	Degree of crystallinity (%)	Release of ropinirole (%) at 40 h
Poly(propylene azelate)	29.8	100
Poly(propylene pimalate)	43.9	98
Poly(propylene glutarate)	55.4	40
Poly(propylene adipate)	67.5	20

drug release rate (Kamaly et al., 2016), as well as degradation of drug molecules (Makadia and Siegel, 2011). An earlier study found that for poly(lactic-co-glycolic) acid (PLGA), an increase in the ratio of hydrophobic PLA segments to PGA segments reduced the hydrophilicity of PLGA, and hence a polymer with lower water absorbency and lower rate of polymer degradation (Makadia and Siegel, 2011). Fig. 14.4 shows that an increase in the LA/GA ratio greatly enhanced the degradation rate owing to its higher hydrophilicity. In addition, a higher LA/GA ratio prolonged the release of risperidone entrapped in the copolymer (Amann et al., 2010).

14.2.3 Molecular weight

The molecular weight of a polymer is related to properties such as the solubility, crystallinity, viscosity, glass transition temperature, mechanical strength, and degradability (Stiepel et al., 2022). Takeuchi et al. (2017) studied the effect of the molecular weight of poly(lactide-co-glycolide) (PLCG) on drug release. When compared under identical release conditions, the release of rifampicin decreased when the molecular weight of PLCG increased (Table 14.2). Based on the free volume model, the drug release depends on the molecular chain movement ability. The increase in

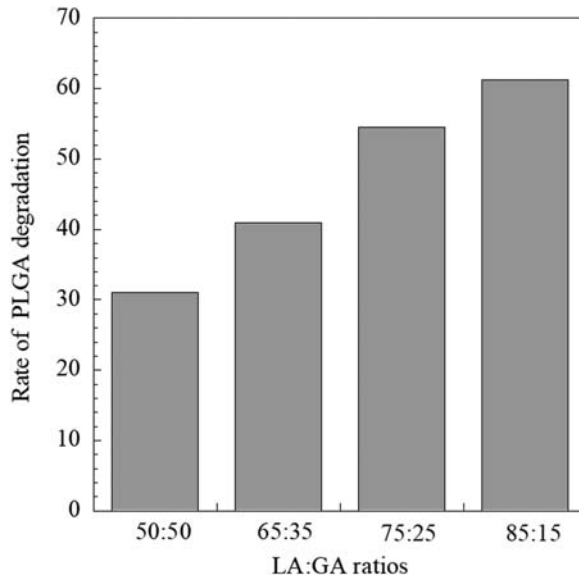

Figure 14.4 Rate of PLGA degradation at different LA:GA ratios. *(Data taken from Amann et al. (2010).)*

Table 14.2 Effect of PLCG molecular weight on rifampicin release (Takeuchi et al., 2017).

PLCG molecular weight	Cumulative release of rifampicin (%)	
	8 h	48 h
10,000	95	95
15,000	87	90
20,000	70	83

molecular weight led to a higher crystallinity and degree of polymerization which hindered the molecular chain mobility.

14.3 Bioresorbable polymers for medical devices

Bioresorbable polymers have been developed and applied as devices in the medical field, especially surgery. Because bioresorbable polymers slowly dissolve in the human body, they do not need to be removed in a second surgical procedure (Oliveira and Mano, 2011). Bioresorbable polymers have mostly been used to prepare valves, stents, screws, and pins, as summarized in Table 14.3.

14.4 Bioresorbable polymers for tissue engineering

Tissue engineering is a rapidly emerging biomedical field that focuses on the development of suitable biocompatible materials to repair or create tissues, or improve damaged tissues or organs via cell transplantation (Biswal, 2021), as depicted in Fig. 14.5.

To apply a polymer in tissue engineering, the suitable properties of the polymer are important and should meet the following requirements:

- A suitable topography and biocompatible surfaces for adhesion and propagation of cells.
- Appropriate mechanical properties that facilitate cell growth and biomechanical functionality.
- Matching of the polymer degradation rate and the tissue formation rate (Biswal, 2021; Ravichandran et al., 2012).

Recently, most polymers in tissue engineering have been constructed in several forms for various applications such as porous scaffolds, hydrogels, and micro/nanoparticles (Biswal, 2021). The characteristic properties and preparation methods of different constructed polymers are discussed in this section.

Table 14.3 Examples of bioresorbable polymers used in medical devices.

Applications	Polymers	Properties	References
Heart valve	Bis-urea-modified polycarbonate	Successful application in sheep with sustained functionality of up to 1 year	Kluin et al. (2017)
Coronary artery stents	3D-printed polycaprolactone functionalized with heparin	Good mechanical strength and biocompatibility for up to 12 weeks in rabbits.	Shen et al. (2022b)
Bone screw	Poly(glycerol-succinate)	Good mechanical strength (122.01 ± 8.82 MPa). Supported cell adhesion and proliferation Good osseointegration in the implanted rabbits	Cai et al. (2019)
Pin	Poly-L-co-D-lactide reinforced with bioresorbable glass fibers	Load bearing and substrate for a bone-like apatite formation.	Cao et al. (2019)

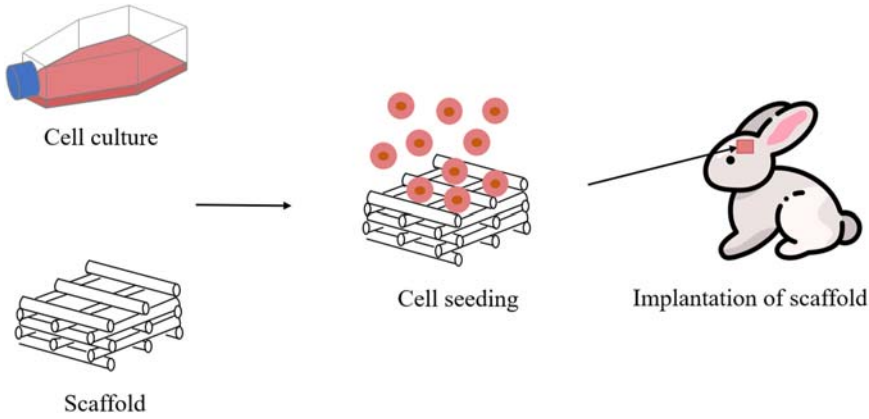

Figure 14.5 Schematic of scaffold-based tissue engineering.

14.4.1 Scaffolds

Scaffolds are porous materials that can deliver biofactors (such as cells, genes, and/or proteins) and repair tissues. The basic required properties for scaffolds include: (1) suitable topology for nutrient transport, cell attachment, proliferation, and differentiation; (2) controllable degradation without risk of cell inflammation; (3) suitable mechanical properties for formation of new tissue; and (4) minimal/no inflammation or in vivo toxicity (Thorrez et al., 2008). The porosity (including both pore size and structure/interconnectivity) of the scaffold is critical for successful integration of cells. Large pores lead to good mass transfer properties of nutrients, oxygen, and waste products, but cell adhesion is low. Small pores, on the other hand, have good integration of cells but poor mass transfer properties. It is therefore crucial to optimize the porous structure of scaffolds. Optimal pore size greatly depends on the site of application; for example, the optimal pore size is 20–80 μm for hepatocyte in-growth, 150–200 μm for fibroblast in-growth, and 100–500 μm for bone regeneration (Salerno et al., 2012).

Scaffolds can be prepared from various materials. Compared to rigid materials such as metals and ceramics, polymeric scaffolds have the advantages of superior processability, adjustable degradation rate, wettability, and good mechanical properties including flexibility, making them especially attractive for applications in organs such as the skin, liver, heart, and bladder (Ambekar and Kandasubramanian, 2019).

Polymer-based scaffolds have been fabricated by techniques such as solvent casting/particulate leaching (SCPL), freeze-drying, gas foaming,

thermally induced phase separation (TIPS), and electrospinning (Mabrouk et al., 2020). The advantages and limitations of these scaffold fabrication methods are summarized in Table 14.4.

SCPL is the oldest technique for scaffold preparation (Mabrouk et al., 2020). In a typical SCPL process, the target polymer is dissolved in a suitable solvent and cast into a mold containing a porogen (most commonly NaCl), after which the solvent and the porogen are removed. This way, highly porous scaffolds have been made from, e.g., PLA (Huang et al., 2014; Zeng et al., 2017), PCL (Yang et al., 2006), polyurethane (PU) (Sin et al., 2010; Sola et al., 2019), and silk fibroin (Raggio et al., 2018). For example, Zeng et al. (2017) prepared a three-dimensional porous PLA scaffold via vacuum-assisted SCPL. The PLA was dissolved in a dioxane/water mixture and cast into a NaCl preform under vacuum. The composite blend was then frozen at −20 to −80°C, after which the dioxane was removed by solvent extraction in ethanol followed by removal of the NaCl by leaching in DI water. The resulting porous PLA scaffold was dried and subsequently coated with chitosan and biofunctionalized with osteogenic growth peptide (OGP). The porous PLA/chitosan/OGP scaffold had a good interconnected network structure with porosity >90% and could accelerate osteoblast proliferation.

Freeze-drying or lyophilization is a simpler technique for the preparation of scaffolds, for example, based on PCL (Fereshteh et al., 2016), poly(hydroxybutyrate-co-valerate) (Sultana and Wang, 2008), poly(lactide-co-glycolide) (Qi et al., 2020), gelatin (Wu et al., 2010), and mixed polymers (Haghbin et al., 2020). In this process, a liquid sample is first frozen and then transferred to a freeze drier, which removes the frozen solvent by sublimation. The sublimation process results in the creation of pores in the spaces that were previously occupied by the ice crystals. Most freeze-drying processes have been carried out in aqueous solution, although organic solvents have also been used (Hou et al., 2003). Important parameters that can affect the resulting material properties are the solution properties (such as concentration, viscosity, solvent) and the freezing conditions (e.g., temperature, pressure, and direction of freezing). For example, smaller pores are formed at lower freezing temperatures. In the work of Mandal and Kundu (2009), silk fibroin protein scaffolds prepared by freeze drying had a porosity of 86% and pore sizes of 200−250 μm when frozen at −20°C. Decreasing the freezing temperature to −196°C resulted in a higher porosity of 96% and smaller pore size of 80−100 μm. Both the porosity and pore size decreased with increasing solution concentrations.

Table 14.4 Advantages and limitations of scaffold fabrication methods (Mabrouk et al., 2020).

Methods	Polymers	Advantages	Limitations	References
Solvent casting/ particulate leaching	Polycaprolactone Silk fibroin PLA	Simplicity Controlled pore size and pore distribution Low cost	Potential impurities from solvent and porogen Nonuniform distribution of porogen in polymer solution	Dhandayuthapani et al. (2011), Yang et al. (2006), and Zeng et al. (2017)
Freeze-drying	Poly(hydroxybutyrate-co-valerate) Polycaprolactone/chitosan/ gelatin Poly(lactide-co-glycolide)/ poly(trimethylene carbonate)	Water can often be used as solvent Highly interconnected pores	Uncontrolled pore size Slow process High energy consumption	Haghbin et al. (2020), Qi et al. (2020), and Sultana and Wang (2008)
Gas foaming	Poly (propylene carbonate) Polyurethane Polycaprolactone/ magnesium hydroxide	One-step process Porosity control without toxic solvents	Closed and unconnected pores Relatively poor mechanical properties	Han et al. (2021) and Manavitehrani et al. (2019)

Thermally induced phase separation (TIPS)	Poly(lactic-co-glycolic acid)	Simple equipment and procedure Intrinsically interconnected polymer network Scalable Good mechanical properties	Potential impurities from organic solvent	McKenna et al. (2020)
Electrospinning	Poly (ε-caprolactone) Polyethylene oxide Gelatin/polycaprolactone	Simple and inexpensive setup Highly interconnected pores High surface area to volume ratio	Limited scaffold thickness Relatively poor mechanical properties	Feng et al. (2019), Hodge and Quint (2019), and Surmenev et al. (2022)

Similar results were found for other polymers (Perez-Puyana et al., 2019; Reys et al., 2017). Furthermore, a lower freezing temperature increased the compressive modulus of chitosan scaffolds (Reys et al., 2017).

In the gas foaming process, gas bubbles are utilized to generate pores. These bubbles can be produced in situ by chemical reactions, or an inert gas like N_2 or CO_2 can be externally introduced (Dehghani and Annabi, 2011). Commonly, a surfactant is added to improve the stability of the foam. Important parameters to control the material properties include the foaming temperature, pressure, and depressurization rate. Scaffolds have been prepared by gas foaming using various polymers (Dehghani and Annabi, 2011) such as PCL (Salerno et al., 2012), PLA (Sheng et al., 2015), alginate (Catanzano et al., 2018; Costantini et al., 2016), and poly(propylene carbonate) (PPC) (Manavitehrani et al., 2019).

Salerno et al. (2012) prepared PCL scaffolds via a gas foaming technique. Thermoplastic gelatin (TG) was blended with PCL and pressed into 3 mm-thick plates, which were solubilized with the blowing agent [N_2/CO_2 (4/1 vol.% ratio) mixture] in an autoclave. The autoclave was then heated to 70–110°C and the pressure was reduced to ambient pressure. After rapid cooling to room temperature, the samples were placed in water for leaching of TG followed by drying. Higher foaming temperatures produced PCL foams with a higher porosity (ranging from 60.2% to 90.3%) and larger mean pore size (from 264 to 1830 μm). At the same time, the elastic modulus was reduced from 9.4 to 1.4 MPa. Biocompatibility tests confirmed the good interaction between the porous scaffold and human mesenchymal stem cells.

Manavitehrani et al. (2019) prepared porous scaffolds from PPC blended with starch and bioglass particles. The porous scaffolds were prepared by gas foaming through the introduction of CO_2 and the effect of parameters such as temperature (25–40°C), pressure (50–125 bar), and depressurization rate (0.02–10 bar/s) on the porosity and compressive modulus was studied. Higher porosity and smaller pores were obtained for higher pressures and lower depressurization rates, and increasing the pressure decreased the compressive modulus. The in vitro evaluations confirmed the safety and biocompatibility of the scaffold and in vivo evaluation in mice demonstrated good tissue infiltration.

Han et al. (2021) prepared a PU foam scaffold via a one-pot process with PCL diol/triol as polyol, hexamethylene diisocyanate (HMDI) as diisocyanate, water or aqueous gelatin as blowing agent, and silicone surfactant as foam stabilizer. Polymerization took place between PCL diol/

triol and HMDI, and CO_2 gas was generated by the reaction between HMDI and water. The resulting highly porous scaffolds were further treated with sulfuric acid to enhance the outer porosity. The influence of the polyol structure, blowing agent, and surfactant concentration on the porosity, mechanical properties, and biodegradability were investigated.

In the TIPS process, the polymer is first dissolved at elevated temperature and then cast into a specific shape. Next, the solution is cooled, during which the polymer solidifies. The solvent is then removed and a microporous polymer structure is formed as a result (Liu et al., 2016). This simple, scalable technique has been widely employed to produce porous scaffolds of various polymers. For example, Rowlands et al. (2007) prepared PU, PLGA, and PU/PLGA composite scaffolds by TIPS. The authors report that the composite scaffold had superior porosity, mechanical, and fibroblast adhesion properties over scaffolds prepared from individual polymers. Zhang et al. (2015) prepared silk fibroin (SF)/sodium alginate (SA) composite scaffold by TIPS. Scaffolds with an SF/SA ratio of 5:1 and 3:1 had high porosity and nanofibrous structure with physical interactions between SF and SA. Cell studies with MG-63 osteoblast cells showed good cellular adhesion and growth. McKenna et al. (2020) prepared thin, porous, high-strength biphasic scaffolds by encapsulation of PLGA mesh into a porous PLGA network by TIPS. The authors carefully optimized several synthesis parameters such as the nucleation temperature, template material, and scaffold assembly temperature. According to the optimized procedure, PLGA mesh strips (1×4 cm) were mounted on microscope slides and kept at 40°C. The degassed PLGA + EC solution was then poured into the pores of the PLGA mesh strips, which was then closed with a second microscope slide. The scaffolds and molds were cooled to 4°C, after which nucleation was manually stimulated. The scaffolds were then transferred to water to remove the EC phase at 4°C for 4 days, followed by drying at room temperature. The thin biphasic scaffold had a high porosity with small pore size, high tensile strength, rapid in vitro degradation, and supported the proliferation of HaCaT cells. The authors suggested that the scaffold may have applications for repairing dermal wounds or tubular organs.

Electrospinning has gained wide attention over the last 30 years due to its ease of operation, and more than 200 different polymers have been prepared into fibers by electrospinning (Mabrouk et al., 2020). In the electrospinning process, a polymeric solution is injected into a thin capillary over which a high voltage is applied. Repulsion of electric charges within

the solution counteracts the surface tension of the liquid, after which a jet erupts. The solvent in the jet evaporates and the formed fibers are deposited on a grounded collector (Pham et al., 2006). The properties of the fibers can be controlled by varying solution parameters (e.g., concentration, surface tension, and conductivity), polymer properties (such as the molecular weight), experimental conditions (such as the voltage, flow rate, and distance between the needle tip and collector), and ambient parameters (for example the temperature and humidity) (Pham et al., 2006). Feng et al. (2019) prepared a gelatin/PCL nanofiber composite membrane via electrospinning. The fibers had an average diameter of 441 nm and the average pore size of the membrane was 5.6 μm. The breaking strength and Young's modulus were measured in wet (3.2 and 1.5 MPa, respectively) and dry states (4.6 and 28.9 MPa, respectively). A study in a rabbit cardiac adhesion model demonstrated that the membrane was well incorporated. The composite membrane effectively prevented postcardiac operative adhesions and may have applications as pericardial substitutes.

Hodge and Quint (2019) prepared scaffolds by electrospinning of PGA, PLGA, and PCL. To enhance the porosity of the fibers, polyethylene oxide (PEO) microparticles were electrosprayed simultaneously with the electrospun fibers. The PEO microparticles acted as sacrificial material (porogen) and were removed from the scaffolds using ethanolic solutions. The porous fibers had high porosity (83%–90%), good mechanical strength (ultimate tensile strength 2.5–6.0 MPa) with low elasticity (Young's modulus 9–86 kPa), and improved cell infiltration and proliferation of human fibroblasts.

14.4.2 Hydrogels

Hydrogels are water-swollen cross-linked polymer networks that can be used to accelerate tissue formation, absorb body fluids, and control the release of active agents (Ounkaew et al., 2020, 2023). Two types of cross-links can exist in hydrogels, namely chemical and physical cross-links (Fig. 14.6). Chemical cross-links are formed via covalent bonding, whereas physical cross-links involve noncovalent interactions and entanglement of the polymeric chains. Recently, hydrogels integrated with smart properties have been developed that are triggered by stimuli such as a change in pH or temperature. Cross-linked hydrogels with reversible or noncovalent cross-links can create smart functions such as self-healing and shear-thinning behavior (Spicer, 2020). For example, the cross-linked hydrogel based on carboxymethyl starch and polyvinyl alcohol via boric

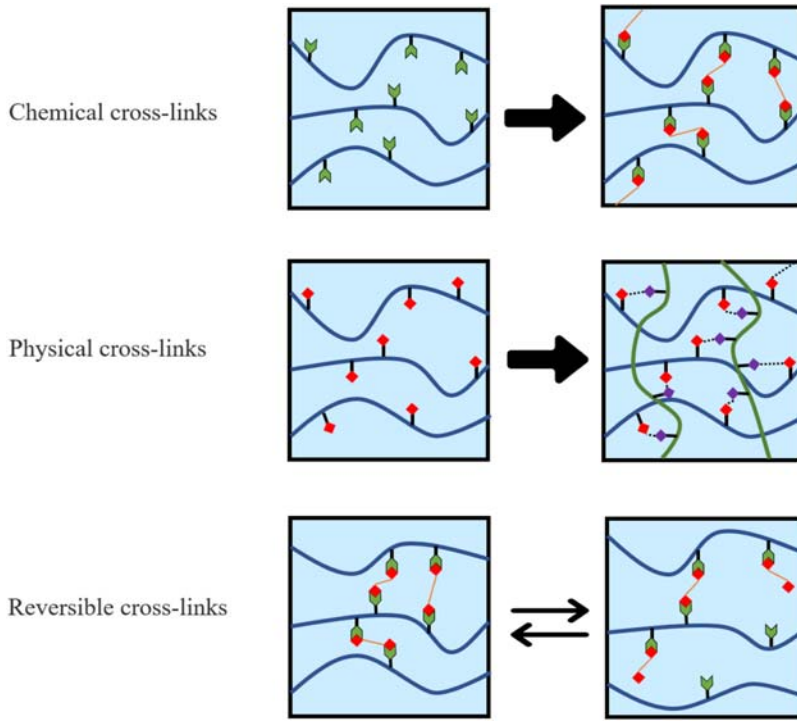

Figure 14.6 Types of cross-linking networks of hydrogels.

ester had self-healing ability (Ounkaew et al., 2022; Taesuwan et al., 2022). To prepare hydrogels, both synthetic polymers and polymers derived from natural resources have been used. Examples of hydrogels and their applications are provided in Table 14.5.

Hydrogel preparation methods can be roughly classified into physical cross-linking and chemical cross-linking techniques. In the case of physical cross-linking, the hydrogel is formed by an interaction between molecules such as ionic interaction, hydrogen bond, crystallization, and hydrophobic interactions. The preparation of hydrogels via physical cross-linking could provide outstanding properties such as ionic conductivity, response to external stimuli, and self-healing ability. However, the prepared hydrogels generally have poor mechanical properties for some applications and complex preparation. Chemical cross-linking processes have been developed to fabricate hydrogels with good mechanical properties and stability (Ahmed, 2015). The preparation methods of hydrogels are summarized in Tables 14.6 and 14.7.

Preparation methods	Process	References
Conjugation reaction	Conjugation by Michael addition reaction, Schiff's base reaction, and Diels—Alder addition reaction. These reactions could take place under mild conditions	Lu et al. (2021)
Free radical polymerization	Free radicals are generated by various techniques i.e., heating, electrolysis, ultraviolet or high-energy radiation, and plasma initiation. After initiation of the free radicals, these functional groups further polymerize or cross-link under suitable conditions by heating or light irradiation to form covalent bonds	Darge et al. (2019), Eke et al. (2017), and Kang et al. (2018)

14.4.3 Micro/nanoparticles

Micro- and nanoparticles are particles with sizes of 1—100 μm and 1—100 nm, respectively. Their smaller size results in a larger surface area, mobility, and high reactivity compared to the bulk materials (Kohane, 2007). The large surface-to-volume ratio of micro- or nanoparticles increases the number of reaction sites compared to macro-size particles. The particle size is of prime importance and largely depends on preparation techniques and applications. For example, injected particles should have a size between 20 and 300 nm in order to prevent rapid elimination by the liver, spleen, and kidneys (Arruebo et al., 2007; Moscatelli and Sponchioni, 2017).

Among the different polymers, polyesters and their copolymers have been widely investigated. Particularly, PLA, PGA, and PLGA have been

Table 14.7 Preparation of hydrogel by physical cross-linking

Preparation methods	Process	References
Ionic interaction	Ionic interactions can be formed by dynamic interaction between positive and negative charged groups of polymer or metal–ligand interactions Examples: **(1)** the use of negatively charged acrylic acid monomers and positively charged 2-hydroxypropyl trimethylammonium chloride chitosan and **(2)** the introduction of divalent metal ions into the hydrogel, which could create interactions with functional groups of the polymers such as amino, carboxyl and hydroxyl.	Shen et al. (2022a)
Hydrogen bonds	The fabrication of hydrogen-bonding interactions in hydrogel could provide smart properties such as self-healing. The hydrogen-bonding interactions in hydrogel have a dissociation/association behavior. To design hydrogen bonding for hydrogel, several types of polymers such as amides, ureas, urethanes, proteins, saccharides, and DNA would be options for the preparation of supramolecular gelators	Lim et al. (2019)
Crystallization	The freeze–thaw method is commonly used. During the freeze process, ice crystals are formed and the polymer chains become arranged. During thawing, the ice melts and creates a microporous polymer structure. The pore size, mechanical properties, and morphology of the hydrogel depend on the number of freeze–thaw cycles	Su et al. (2021)

studied extensively in medical applications such as drug delivery, bone plates, and abdominal meshes (Lee et al., 2016). PLA and PLGA nanoparticles have also been shown to be useful in drug delivery for tumors. These polymer nanoparticles are particularly attractive as drug delivery vehicles for targeting cancer cells because they can overcome challenges related to the low solubility, stability, and rapid clearance, hence imparting high efficiency. To obtain the desirable properties of PLGA nanoparticles such as particle size, shape, biodegradability, as well as suitable chemical properties, the LA:GA ratio can be easily adjusted. Loading of active pharmaceutical ingredients is usually achieved through homogeneous dispersion in the PLA matrix (Danhier et al., 2012). However, a high initial burst release for drug delivery can be problematic (Kamaly et al., 2012). Some synthesis methods for polyester nanoparticles are summarized in this section.

Various techniques have been carried out to prepare micro- and nanoparticles of the polyesters (such as PLA, PCL, and PGA). The conventional technique is the emulsification-evaporation method. In the single emulsion method, polymers and hydrophobic drugs are dissolved in organic solvents and subsequently added to a mixture of water and surfactants to form an oil-in-water (o/w) emulsion. To form a nanosized dispersion of particles, homogenization, milling, and sonication at ultrasonic frequency are applied. The agitation rate among other parameters is used to control the particle size. Extraction of solvents is subsequently carried out by evaporation under low pressure. The limitation of this method lies in its poor encapsulation of hydrophilic compounds.

The double emulsion process is suitable when hydrophilic compounds such as proteins or peptides drugs are used. This method allows a higher drug loading for water-soluble compounds such as insulins. This process involves an additional step where water-soluble drugs are dissolved in the water mixture containing a proper stabilizer to form an aqueous phase. The water-soluble drug solution is then added to organic solvents containing polymers to form a w/o (water-in-oil) emulsion or an o/w emulsion. This emulsion is subsequently added to a mixture of water and a stabilizer, resulting in w/o/w or o/w/o emulsions. Finally, the removal of organic solvents is carried out under vacuum (Lee et al., 2016).

Emulsions such as o/w, o/o (oil-in-oil), or w/o can produce particles with various sizes from the nano- to micrometer scale. Although these techniques are simple, they suffer from several negative aspects including the production process, the use of potentially toxic solvents and surfactants,

wide size distribution, low solid content, and the need for high-molecular-weight polyesters (Moscatelli and Sponchioni, 2017). In addition, a polymeric shell needs to be rapidly formed in the first emulsification step in the double emulsion method to avoid diffusion of the hydrophilic compound into the outer (bulk) aqueous phase (Moscatelli and Sponchioni, 2017).

Salting out is a different approach to emulsification in which no heating step is required. In this process, the polymers are mixed with water-miscible solvents and added to a salting-out agent (often $MgCl_2$ or $CaCl_2$) in the presence of a stabilizer under high-speed stirring to form a colloid. Subsequently, this o/w emulsion is diluted in water to allow the miscible solvent to diffuse into the aqueous phase. Lastly, the particles are separated from the liquid phase by centrifugation or cross-flow filtration. This technique is particularly interesting for heat-sensitive drugs.

Nanoprecipitation is another means of polymer nanoparticle preparation. This facile technique does not require any high-energy source stirring device and offers nanoparticles with narrow size distribution where less toxic solvents can be used. The nanoparticles can be obtained with the aid of antisolvents followed by solvent removal under reduced pressure. The particle size and drug encapsulation yield can be controlled by the injection rate of the organic phase into the antisolvent and the solvent types. The limitation of this technique is the narrow condition of the Ouzo region used to form nanoparticles with high drug encapsulation efficiency (Anton et al., 2008; Ganachaud and Katz, 2005; Sah and Sah, 2015). In a similar category as the nanoprecipitation technique, other techniques based on precipitation such as dialysis have also been used to achieve particles with a narrow size distribution.

Spray drying has been used to improve the stability of protein encapsulates (Wischke and Schwendeman, 2008). Solutions containing the drug and polymer are sprayed into ultra-fine droplets followed by rapid evaporation of the solvent, after which nanoparticles are obtained.

Microparticles can also be produced through thermal treatment. Hot melt encapsulation is a suitable method to produce particles ranging from 1 to 1000 μm with a narrow size distribution (Sinchaipanid et al., 2004). In addition, no solvent is needed since the drug is dispersed in the molten polymer. The drug/polymer melt is then cooled to solidify and ground or milled to obtain the desired particle size. Although hot melt encapsulation is an attractive technique for large-scale production (Sinchaipanid et al., 2004), denaturation and degradation of the molecules are the main concerns because of the high temperatures involved.

Table 14.8 Applications of micro- and nanoparticles in tissue engineering.

Key factors	Polymers	Properties	Applications	References
Particle size	Alginate/calcium phosphate cement (CPC) paste containing human umbilical cord mesenchymal stem cells	Microbeads (73 −465 μm) provided a four- to seven-fold higher mechanical strength when compared to larger beads (2−3 mm)	Bone repair	Zhao et al. (2010)
Surface topography	Poly(ethylene glycol) diacrylate	Wrinkled surface on the particles promoted cell attachment with a larger surface area when compared to smooth ones	Cell carriers	Li et al. (2016)
Pore size	Polycaprolactone porous beads	After 7 days of testing, beads with pore sizes of 50−100 μm showed higher cell growth than those of 25−50 μm. The suitable pore size provided more efficient transport of nutrients or metabolites for cell growth	Cell carriers	Lim et al. (2009)

The supercritical fluid technique is an attractive and environmentally friendly method in which CO_2 is used as a nonsolvent. This technique overcomes the drawbacks of the conventional methods as it uses mild temperature, avoids the necessity of toxic solvents, and is capable of fabricating nanoparticles with narrow size distribution and uniform drug distribution. The products are free of any residual solvents and the structure and functionality of the active ingredients are unaltered. To produce micro/nanoparticles, the solution containing polymer and bioactive agent is sprayed into a supercritical fluid (typically supercritical CO_2). The solvent dissolves in the supercritical fluid and the polymer (nano)particles form by precipitation. Fine-tuning of the product properties can be done by optimizing process conditions such as temperature and pressure. The major drawback of this method is the high cost and poor solvent power of CO_2 (Paliwal et al., 2014).

Different synthesis approaches have been developed to produce micro/nanoparticles with remarkable properties and versatile structures. Apart from the discussed manufacturing techniques, there are other techniques such as electrospraying, coacervation, gelation, grinding, and microfabrication, which have been considered for micro/nanoparticle production, suitable for certain applications. Moreover, innovative methods to produce micro/nanoparticles with desired particle size using the emulsion-polymerization method are discussed by Moscatelli and Sponchioni (2017).

The medical applications of micro/nanoparticles started with drug delivery and were further developed as cell support in tissue engineering. Some examples of the use of micro/nanoparticles in tissue engineering can be seen in Table 14.8.

14.5 Conclusions

Bioresorbable polymers have shown great promise in medical devices and provide significant advantages over traditional devices, especially in short-term applications. Due to the wide range of both synthetic and especially natural polymers available, the polymers and their composites can be carefully designed through careful tuning of material properties such as crystallinity, molecular weight, and hydrophobicity in order to meet the requirements for specific applications. However, bioresorbable polymers are still under development and have primarily been tested in controlled laboratory environments. Their functioning needs to be demonstrated on a larger scale in more realistic settings before they can be used in practical applications.

CHAPTER 15

Bioresorbable polymers for wound healing

Sheikh Shahnawaz Quadir[1], Dinesh Puri[2], Garima Joshi[1], Deepak Choudhary[1], Sanket Kumar[1], Monika Singh[3] and Shalini K. Sawhney[3]

15.1 Introduction

Over the last decade, polymers have played a vital role in medicine. Among these, bioresorbable polymers have gained increased attention due to their unique potential in medicinal formulations and represent a diverse family in the field of biomaterials. The term biomaterial was coined in 1982 at NIH Consensus Development Conference, describing clinical uses of biomaterials. It is defined as "any substances or a combination of the substances other than drug which is either natural or synthetic in nature can be used in any period of time for the treatment, replacement or augmentation of any tissue, organ or a function of the body." Other definitions include that in the William Dictionary of Biomaterials (1999), which states that "nonviable materials which is utilized in the medical devices, intended to interact with the biological system", and also "A material which is synthetic, natural or modified natural material (other than drug) intended to interact with the biological system or a part of system that are able to treat, replace or augment a tissue, organ or a function of the body" as described in Dorland's Medical Dictionary (Pertici, 2017).

Bioresorbable compounds are those compounds which alter their chemical and physical structure when they came into contact with a biological system. If a compound is bioresorbable in nature, by applying correct conditions in the presence of fungi, bacteria, or microorganisms, it will automatically break down to its basic structure. The key benefits of such compounds include that they degrade without leaving any toxins behind. The word bioresorbable

Bioresorbable Polymers and their Composites

means biodegradable or naturally absorbing, which is used to define the process of breaking down by nature. However, bioresorption highlights the process which leads to the slowly disintegration of a compound into fractions inside the human body. When this compound comes into contact with body fluids, it alters its physicochemical properties resulting in physical, chemical, biological, and mechanical characteristics among the compounds and neighboring environment. These compounds are easily metabolized without showing any toxic effects and then cleared from the body (Agubata et al., 2021).

The major utilized bioresorbable compounds in medicine are ceramics, and polymeric and metallic materials. Bioresorbable polymers have been described as "today's material." In the current era, bioresorbable polymers have attracted the attention of researchers and scientists due to their potential in the tissue engineering and biomaterials fields. Meanwhile, in medicine, bioresorbable polymers possess significant applications in wound healing (i.e., sutures, adhesives, staples, etc.) and controlled drug delivery. They are also used in ligaments for orthopedic devices, along with nonwoven materials and scaffolds in tissue engineering. These bioresorbable polymers also offer great applications in a number of domains such as dental, drug delivery, biological devices, biosensors, nanoparticles, and nanocarriers, as well as for in vitro diagnostic tools, etc. (Daniel, 2021).

Wounds can be defined as any lesion which occurs to the skin or other body tissues either by cuts, scratches, scrapes, or other accidental damage. Hence, for the treatment of such wounds, wound healing is needed. To regenerate and repair dermal and epidermal tissues, dressings are widely used in the wound-healing process. Wound dressing materials are materials which act as a barrier to foreign particles, oxygen, and moisture to combat and protect against microorganisms (Mogosanu and Grumezescu, 2014). A passive dressing is important for maintaining optimum moisture, which helps in stimulating the wound-healing process. An ideal passive dressing material is one which influences the local cellular response for the treatment of wounds and burns such as cellulose, collagen, alginates, hydrogels, foams, cotton, hydrocolloids, etc. (Cornelius et al., 2006). These materials offer various key benefits in wound healing, e.g., maintenance of suitable moisture levels in wounds, minimizing the pain and itching, cleansing of damaged tissues, and eliminating dead spaces and nonviable tissues (Sawant et al., 2012). Some of these materials which are naturally available can progressively improve wound healing due to their emollient, antimicrobial, antiinflammatory, antioxidant and epithelializing properties.

Skin tissues have their own key potential, including structural organization and self-repairing ability. However, once they become injured by sufficiently large lesions, healing and recovery become suboptimal. In such cases, bioresorbable polymers play a vital role by restoring the native tissues or replacing them with engineered alternatives. This chapter emphasizes the factors which influence the healing process and the important applications of bioresorbable polymers in wound healing. It provides a framework for understanding the strategies of such polymers that could be key in the development of future therapeutic applications.

15.2 Wound-healing process

A wound is a skin lesion which occurs due to physical, chemical, thermal, or other tissue or systemic pathology. A wound is categorized on the basis of its severity, such as partial, superficial, or full thickness. The partial-thickness wound may have damage to the superficial layer, i.e. the epidermis (up to the dermal layer), and healing can take a few weeks. Superficial wounds only affect the epidermis, but healing can be successful through unaffected keratinocytes. The most difficult to treat and severe wounds are full-thickness wounds which can take several weeks to heal and still be suboptimal. These wounds include major damage to both the tissues of the epidermis and dermis (Mogosanu and Grumezescu, 2014). The above-listed wounds occurs in three stages, i.e., inflammation, proliferation, and remodeling (Danti et al., 2017).

Inflammation: In the inflammatory process, platelets play a vital role by forming a fibrin clot soon after the injury which permits the infiltrating cells to gather in the lesion area to prevent bleeding. Additionally, these platelets attract growth factors by initiating a cascade of events such as monocytes, neutrophils, and fibroblasts. They also induce fibroblasts to secrete fresh extracellular matrix.

Proliferation: The second process of wound healing is categorized as reepithelialization and connective tissue regeneration. Reepithelialization is a process started by proliferating keratinocytes which travel toward the lesion site. These new blood vessels develop side by side and fibroblasts gather from nearby areas to deposit extracellular matrix molecules (collagen fibers, elastin, glycosaminoglycan) and granulocytic tissues.

Remodeling: The final step in wound healing may take many year until the restoration of the entire dermis through constant tissue remodeling.

This step proceeds by replacing collagen type III with collagen type I through the secretion of matrix metalloproteinase. There are also some wounds which occur due to pathological and disease conditions, such as diabetes, which are unable to heal completely. Hence, such wounds become chronic by sustaining inflammatory events which become difficult for the growth factors to perform a healing function, resulting in the development of pathological constraints such as tumors and persistent infections.

15.3 Factors affecting wound healing

There are various factors that may impede the wound-healing process. In simple terms, those factors which affect the repair mechanism are divided into local and systemic. The local factors are those which directly damage or influence the process of wound healing by altering its characteristics, and systemic factors are those which affect the healing abilities of an individual in healthy or diseased condition (Fig. 15.1). In the majority of cases systemic factors occur due to local factors which influence wound healing (Guo and DiPietro, 2010).

15.3.1 Local factors that influence the healing process

15.3.1.1 Oxygenation

Oxygenation is crucial for the production of energy by means of ATP, cell metabolism, and for recovery from almost all types of wounds. It possesses several benefits in healing, such as the protection of wounds from infection by promoting angiogenesis, enhancing keratinocyte uptake, migration, and

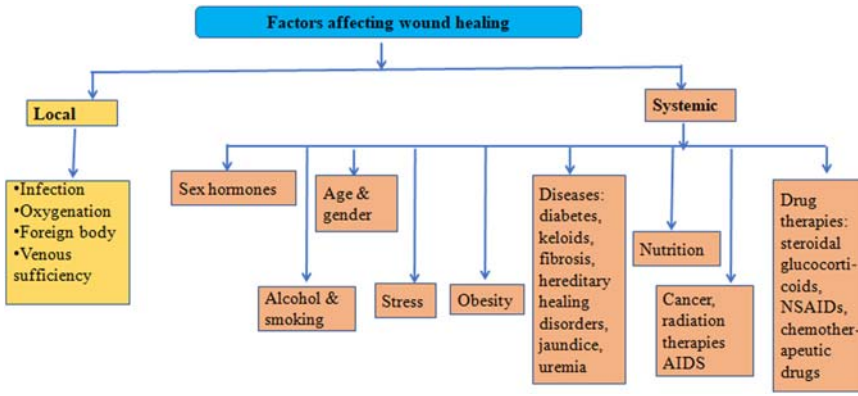

Figure 15.1 Factors affecting wound healing.

reepithelialization. It also promotes fibroblast proliferation around wounds along with the formation of collagen. Moreover, it increases the level of superoxide production with the help of polymorphonuclear leukocytes as a primary dependent oxygen factor (Bishop, 2008). There are several systemic conditions such as age and diabetes which can decrease the vascular flow, resulting in the development of hypoxic wounds due to poor tissue oxygenation.

Healing is diminished for those wounds which are unable to restore oxygen. A temporary lack of oxygen (hypoxia) can activate wound healing only if it happens for a long time, otherwise wound healing can be delayed. A lack of oxygen can impact cytokine and growth factor production. Cytokines formed due to a lack of oxygen include transforming growth factor-beta, platelet-derived growth factor, vascular endothelial growth factor, tumor necrosis factor, etc. ROS such as hydrogen peroxide and superoxide are majorly involved in normal wound healing and behave as cellular messengers to promote the wound-healing process, cell motility, cytokine action, and angiogenesis. Hypoxia and hyperoxia are responsible for enhancing ROS demand. However, on other hand, a higher level of ROS production can damage tissues (Rodriguez et al., 2008). To conclude, proper oxygen supply is essential for the success of the wound-healing process.

15.3.1.2 Infection and foreign bodies

Once a lesion is present on the skin, microorganisms gather at the skin surface and enter the underlying tissues. The level of the infection and replication state of the microorganisms affect whether the wounds are colonized, contaminated, or spread the invasive infection. The availability of nonreplicating microorganisms on wounds is identified as contamination. Meanwhile, the presence of replicating microorganisms on a wound without any tissue damage is described as colonization. Local infection and critical colonization are found at an intermediate stage where microorganisms can replicate and local tissue actions are started. An invasive infection is defined as the availability of replicating microorganisms inside a wound (Harding and Edwards, 2004).

On the other hand, inflammation is a basic response in the wound-healing process and an essential factor for the removal of contaminated microorganisms. If microbial removal is not completed, inflammation is sustained for a longer duration. Due to such conditions, bacteria and endotoxins both enhance cytokine production (IL-1 and TNF-alpha) which increase the inflammatory phase. If this happens for a longer time, the

wound is considered as chronic and is difficult to heal. Moreover, such a prolonged inflammatory state may elevate the production of metalloproteases which are responsible inhibiting the extracellular matrix in wounds (Menke et al., 2007).

15.3.2 Systemic factors that influence the healing process

15.3.2.1 Age

As per WHO, the over 60 years age group is growing faster than any other age group. Higher age of individuals is one of the critical risk factors in the impaired wound-healing process. Many clinical and animal studies conducted at the molecular level have revealed that higher age can adversely impact wound healing (Keylock et al., 2008). In the aged individual, altered inflammatory reactions, i.e., T-cell infiltration, chemokine formation, and lower phagocytic volume around the wound environment, can delay the wound healing. An animal study in aged mice compared with young mice revealed delayed angiogenesis, collagen production, and reepithelialization. In general, there are small differences between young and aged individuals in terms of wound healing. A review study of age-related changes revealed that the each step of wound healing for aged persons showed higher platelet aggregation, higher uptake of inflammatory mediators, delayed permeation of macrophages and lymphocytes, lowered growth factor secretions, and delayed reepithelialization, angiogenesis, and collagen production (Gosain and DiPietro, 2004).

15.3.2.2 Sex hormones in aged individuals

Compared to aged females, aged males are more affected by delays in the wound-healing process due to sex hormones. A female estrogen (estrone), male androgen (testosterone), and there steroidal precursor (dehydroepiandrosterone) have significant effects on the wound-healing process (Gilliver et al., 2007). A study revealed that the expression of genes among elderly men and young women was totally estrogen regulated. Numerous genes associated with wound healing are affected by estrogen, which enables matrix production, and inhibits protease and regeneration of tissues, and the genes those are involved in inflammation (Hardman and Ashcroft, 2008).

15.3.2.3 Stress

Stress has a significant effect on human health and social behavior. Several diseases are associated with stress, such as diabetes, wounds, CVS, and

cancer (Vileikyte, 2007). Clinical research has revealed that both humans and animals with physiological stress can have a hampered wound-healing process. A student with the stress of academic examinations and a caretaker for a person with Alzheimer's have delayed wound-healing processes. Stress is responsible for the up-regulation of glucocorticoid hormones as well as lowering the amount of proinflammatory cytokines (IL-1β, TNF-α, and IL-6) at the wound area. It also inhibits the progression of chemoattractants (IL-8 and IL1-α) which are essential for the initial inflammatory step during the wound-healing process (Boyapati and Wang, 2007).

Moreover, Th1 responses are essential during the starting phase of wound healing, and are regulated by the glucocorticoid cortisol as an antiinflammatory agent. Hence, physiological stress can impair and delay healing at the wound site via reduced cell-mediated immunity (Godbout and Glaser, 2006). Other negative stress factors such as anxiety and depression affect health and behavior as well as being responsible for delaying wound healing. The effects of stress on wound healing are summarized in Fig. 15.2.

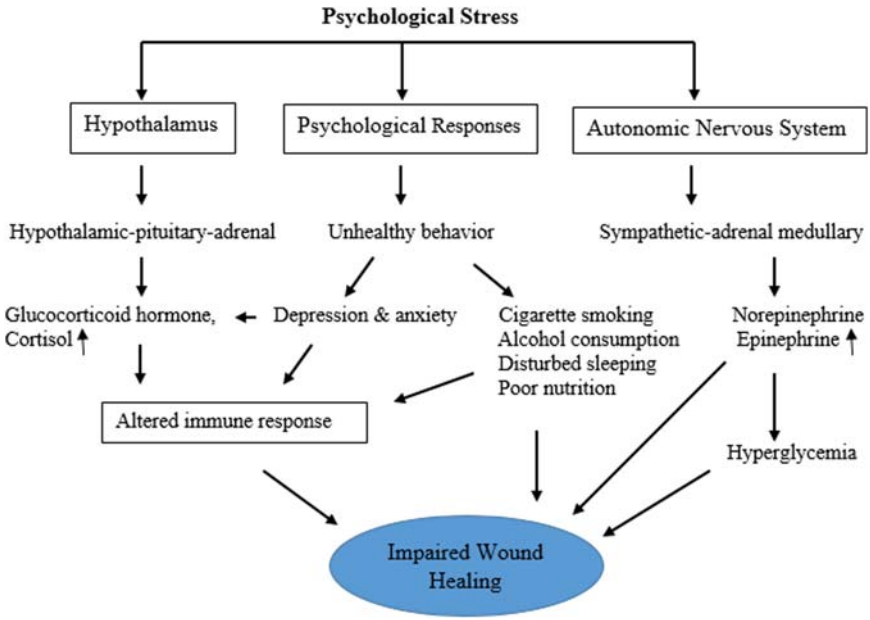

Figure 15.2 The effects of stress on wound healing.

15.3.2.4 Diabetes

An individual who is affected by diabetes shows an impaired healing process in acute wounds. Much of this population is affected by chronic nonhealing diabetic foot ulcers (DFUs). DFUs are a severe condition of diabetes that occur in about 15% of the total diabetic population. A patient with diabetes can experience poor wound healing from both DFUs as well as acute cutaneous wounds due to a variety of intricate pathophysiological processes. DFUs arise to hypoxia, as with venous stasis illness and chronic nonhealing wounds. By elevating the concentration of oxygen radicals, hypoxia can exacerbate the primary inflammatory actions and lengthen the healing process. Diabetes-associated wounds are considered to have a number of dysregulated cellular causes, including inadequate T-cell immunity, faulty leukocyte chemotaxis, phagocytosis, bactericidal activity, and dysfunctioning of epidermal cells and fibroblasts (Woo et al., 2007). Some of the other causes are described in Fig. 15.3.

15.3.2.5 Medications

Numerous drugs have the potential to alter the wound-healing process, including those that hamper platelet function, clot development, inflammatory action, and cell proliferation. Only those drugs categories that are frequently taken and possess major effects on healing are discussed here, such as NSAIDs, glucocorticoid steroids, and chemotherapy therapies.

Glucocorticoid steroids

The glucocorticoids are systemic antiinflammatory drugs that are well recognized as hindering wound healing by suppressing cellular wound

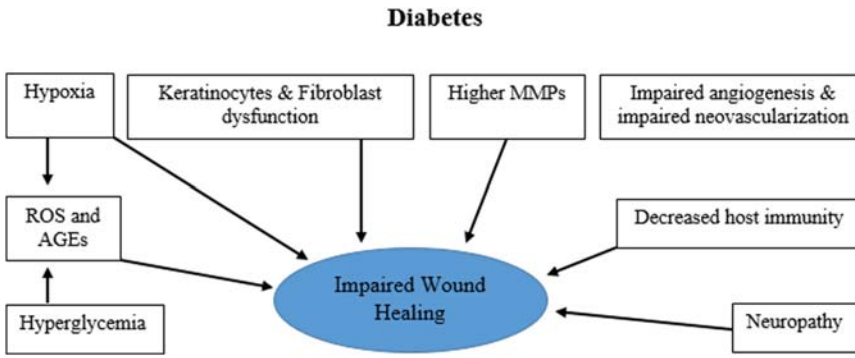

Figure 15.3 Effects of wound healing in diabetes. *AGEs*, advanced glycation end products; *MPPs*, matrix metalloproteases; *ROS*, reactive oxygen species.

responses. i.e., the proliferation of fibroblast and collagen production. These steroids form inadequate granulating tissues and lower wound contraction in the healing process. A critical transcriptional factor associated with wound healing, i.e., HIF-1 (Hypoxia-inducible factor-1), is also inhibited by glucocorticoids (Wagner et al., 2008). Compared to systemic application, topical application of glucocorticoids has quite different effects as it promotes the wound-healing process. Chronic wounds treated with topical low-dose corticosteroids have been shown to heal more rapidly, cause less pain and exudate, and encourage hypergranulation tissue formation in almost 79% of instances (Hofman et al., 2007).

NSAIDs

Ibuprofen is one of the nonsteroidal antiinflammatory drugs (NSAIDs) frequently used to treat inflammation, control pain, and treat rheumatoid arthritis. A low dose of aspirin is frequently used as a primary preventive treatment option for cardiovascular disease but not as an antiinflammatory drug due to its antiplatelet properties (Pertici, 2017). There is little evidence to support the claim that short-term use of NSAIDs impairs wound recovery. However, it remains unclear whether long-term NSAIDs affect how well wounds heal. Moreover, in animal studies, ibuprofen has been shown to have antiproliferative properties on wounds, resulting in lowering of fibroblast content and wound contraction, along with delayed epithelialization and impaired angiogenesis (Pieringer et al., 2007).

Chemotherapeutic drugs

The majority of chemotherapies work by slowing down the cellular metabolism, accelerating cell division, and promoting angiogenesis, all of which are essential for an effective wound-healing process. These drugs prevent the production of DNA, RNA, and proteins, which lower the fibroplasia and neovascularization of tissues. Chemotherapeutic drugs delay cell migration into the wound, decrease early wound matrix formation, lower collagen production, impair the proliferation of fibroblasts, and inhibit the contraction of wounds (Kirchner et al., 2003).

15.3.2.6 Obesity

Numerous infections or diseases, as well as health issues such as diabetes, ischemic heart disease, cancer, hypertension, and delayed wound healing, are known to be made more likely by obesity. People affected by obesity experience several wound complications, such as venous and pressure

ulcers, skin wound infections, seroma, and hematoma development. Obese patients receiving bariatric and nonbariatric procedures have been shown to have a higher frequency of wound problems. Obese people experience a higher rate of surgical site infections and many of these issues occur in subcutaneous adipose tissues due to hypoperfusion and ischemia. This situation also occurs due to lowered intake of antibiotics. Increased tension on the edges of surgical wounds typically occurs in obese patients, resulting in wound dehiscence. Due to wound tension, tissue pressure rises significantly, which hampers the microperfusion process and lowers the capabilities of wounds to consume oxygen (Franz et al., 2007).

15.3.2.7 Alcohol consumption

The use of alcohol hinders the wound-healing process and enhances the risk of infection as per a clinical and animal study report (Anaya and Dellinger, 2006). Due to alcohol exposure, either acute or chronic, in more than half of traumatic events, the impact of alcohol on the repair mechanism is extremely clinically significant. The consumption of alcohol lowers the defense mechanism and being intoxicated at the time of injury increases the likelihood of wound infection (Szabo and Mandrekar, 2009).

15.3.2.8 Smoking

Smoking increases the risk of various malignancies, such as stroke, heart, vascular disease, lung disease ,etc. Similarly, smoking has long been recognized as having detrimental impacts on wound healing (Choudhry and Chaudry, 2006). One study revealed that patients who smoke after surgery experience delayed wound healing and also a number of issues such as wound rupture, infection, leaking, necrosis, epidermolysis, and lowered tensile strength of wounds. In the field of oral surgery, smokers have been found to have lower recovery after both conventional oral surgery and the installation of dental implants (Ahn and Mulligan, 2008).

15.3.2.9 Nutrition

Nutrition has been acknowledged for more than a century as a critical component that influences the wound-healing process. It is clear that inadequate nutrition or specific nutrient deficiency can significantly affect wound healing following trauma and surgery. Patients who are malnourished and have chronic or delayed healing frequently require specialized nourishment. The healing process can be impacted by the metabolism of carbohydrates, proteins, fats, vitamins, and minerals (Balaji, 2008).

15.4 Properties of bioresorbable polymers

For the manufacturing of engineered tissue products, the choice of biopolymer is crucial. Although the traditional selection principle for secure, stable, and inert substances still applies, it has been found that any artificial substances ingested by the patient will have biological reactions. As each biopolymer application necessitates a different environment for cell–cell communication, it is crucial for the engineered tissue product manufacturer to have a variety of biopolymer options available (Zhang et al., 2014). Such applications include:

A. It should support the development of new tissues through the interaction among cells and their potential to obtain nutrients, growth factor, and optimized active pharmaceutically ingredients.
B. It should inhibit the cellular properties of tissue growth where surgically induced adhesions are detrimental.
C. It must lead to tissue responses by increasing the cellular reaction of one and inhibiting the other.
D. It should improve cell–cell connections and cellular activity, such as the formation of ECM, proliferation, and fibroblast attachment.
E. It should inhibit cellular connectivity, such as the connectivity of platelets to vascular grafts.
F. Inhibition of biological activity such as in organ transplantations by blocking antibodies against grafted cells.

When tissue recovery or modifications are the prime object of engineered tissue products, bioresorbable polymers are appropriate; however, they are not appropriate when long-lasting material stability is needed. Hence, bioresorbable polymers also require features such as:

A. Manufacturing feasibility, as well as an excess amount of polymers available commercially.
B. The proficiency to convert the polymer into the final product.
C. The mechanical characteristic that interact in short-term functioning but do not interfere with long-term functioning.
D. Minimum or nontoxicity of breakdown products, in both systemic and local tissue reactions.
E. Possibilities for the development of drug-delivery systems for use in the sustained release of active pharmaceutical ingredients.

Natural and engineered natural substances, along with metals, synthetic polymers, ceramics, and composites, are among the various substances that are mostly used in clinical applications. Metals, including their alloys, are

employed for implants in dental and orthopedic use because of their mechanical potential, such as ductility, toughness, and increased strength. Nevertheless, a metallic implant may have issues that are serious enough to necessitate a second surgery to remove the device, such as irritation brought on by corrosive and erosive conditions in biological systems, secondary fracture of conducted bone, and development of sterile implants. Ceramics and glasses, which can be chemically bioactive or nonbioactive in nature, are utilized in a number of biomedical applications, mostly for rebuilding missing bones, but because of their brittle nature, they are avoided in load-bearing applications (Arnold and Barbul, 2006).

Polymers are less strong and ductile than ceramics, glasses, and metals, however they are commonly utilized for exchanging, increasing, supporting, or fixing live tissues due to their diversity, simplicity, and biocompatible nature. It is feasible to develop composites by mixing polymers, ceramics, and metals to acquire unique qualities which are not present in a single material to develop customized devices for use in numerous biological sectors. Due to the structural similarity in living tissues which are formed of macromolecular composites, synthetic polymer composites are widely appealing biomaterials. The formation of engineered scaffolds, simple sutures, fixing screws, gauze strip, and bone replacements using bioresorbable polymers is a common practice. They do not require any secondary method to remove the implant or to initiate the tissue recovery in the matrix. The major outcome in the development of biomaterial research in the last 30 years has been the gradual transition from bio-stable prostheses to bioresorbable implants (Zhang et al., 2014).

15.5 Bioresorbable polymers for wound healing

Natural polymers offer a variety of benefits in regenerative medicinal therapy for the enhancement of wound healing, such as biodegradability, biocompatibility, and similarity to the extracellular matrix. Natural polymers are engaged in the repair of injured tissues and subsequently in skin regeneration by initiating and promoting the wound-healing process (Huang and Fu, 2010). Biomaterial hydrogels are used commercially, such as in pharmaceuticals and biomedicals, due to their unique 3D cross-linked structures that are soaked in aqueous or biological fluids for wound treatment, drug administration, organ replacement, and engineered tissue products (Das et al., 2012). Additionally, radioactivity studies are used to create innovative biomaterials based on biodegradability, nontoxicity, and

bio-renewable polymers. As a result, hydrogels made of naturally cross-linked polymers are utilized for the healing of wounds and skin burns (Haji-Saeid et al., 2010). The natural bioresorbable polymers for wound healing are described in the following subsections.

15.5.1 Polysaccharides

Polysaccharides are mainly introduced in the form of hydrogels. Some are primarily used for the treatment of wounds and skin burns. The polysaccharides are divided on the basis of their nature, such as those are neutral in nature, i.e., dextrans, glucans, cellulose; acidic in nature, i.e., alginic, hyaluronic acids; basic in nature, i.e., chitin, chitosan; or sulfated in nature, i.e., heparin, keratin, chondroitin, etc. (Kennedy et al., 2001).

15.5.1.1 Homoglycans

Homoglycans are biocompatible biopolymers that are utilized locally to alter the cellular activities involved in wound healing. Starch, dextran, cellulose, or their modified compositions can be used in the manufacture of nanofiber matrices in the regenerative medicinal therapies sector, such as for wound healing and tissue engineering (Lee et al., 2009).

α-Glucans

The common yeast-like fungus *Aureobasidium pullulans* forms pullulan (1-4),(1-6)-d-glucan from starch (Dothioraceae). A pullulan by-product was synthesized using a chemical cross-linking method for antibacterial release during wound healing via a superabsorbent polysaccharide-based hydrogel. Hydrogels possess extraordinary water-absorbing capabilities, with a swelling ratio up to 4000% and are also noncytotoxic, offering rapid hemostasis, while inhibiting fluid aggregation and enabling wound bed dryness. Additionally, drugs such as antibacterials or antimycotic therapies may be encapsulated into hydrogels to protect wounds and skin burns against microbial biofilm invasion (Li et al., 2011).

β-Glucans

β-Glucans possess the capabilities to form single and triple helical durable gel structures, while numerous forms of (1-3)-d-glucans can be isolated from fungi, yeast, and grains to identify the pharmacological and immunological properties. A study conducted by Lehtovaara et al. revealed that highly pure yeast-derived insoluble (1-3)-d-glucan considerably minimized skin irritation, blocked adipogenic division, and aided

the wound-healing process (Lehtovaara and Gu, 2011; Vetvicka and Vetvickova, 2011).

Dextrans

Dextran that has been modified to possess heparin-like qualities is known as carboxymethyl benzalamide sulfonate dextran (CMDBS), which is utilized for the treatment of wounds and skin burns. In general, CMDBS is a soluble polymer which possesses structural similarity with glycosaminoglycan heparin by enhancing the wound-healing process. In the majority of in vivo studies, it has been shown to be capable of inhibiting *Staphylococcus aureus* biofilms and promoting the cell proliferation and metabolism of various cells such as tumor, smooth muscle, and endothelial cells. Recently, cyclodextrins (hydrated) have been utilized as odor-control dressings due to their bucket-shaped structure which is capable of trapping and neutralizing water-insoluble particles. Cyclodextrin can be active for a long time than charcoal or serum proteins, which makes them excellent candidates to absorb odors more effectively (Logeart-Avramoglou and Jozefonvicz, 1999).

Cellulose

For chronic wound dressings, bioengineered cellulose is utilized superficially as a healing scaffold or matrix material, which minimizes discomfort and pain, and accelerates the healing process. Cellulose also possesses key benefits in wound healings such as enhancing granulation and epithelialization of partial- and full-thickness wounds. Various bioactive molecules, such as enzymes, hormones, vitamins, antioxidants, and antimicrobials, can be incorporated through a co-immobilization process using engineered cellulose for wound healing (Medusheva et al., 2007).

Chitin and chitosan

The most common natural amino polysaccharide is chitin (polu-N-acetyl-glucosamine), which is readily accessible throughout the year like cellulose. It makes up the majority of the exoskeletons of insects, crustaceans, and vertebrates, and also the cell walls of fungi. Chitin is transformed into chitosan (poly-N-acetyl-glycosaminoglycan) via the alkaline deacetylation process and by reacting the shells of shrimps with sodium hydroxide (Morganti et al., 2011). Several chitin and chitosan compositions with local hemostatic, antimicrobial, antiinflammatory, and wound-healing characteristic have been developed, such as water-soluble chitin ointment for

wound-healing treatment (Han, 2005) and chitin-loaded silver nanoparticles as a bactericidal film for wound healing (Madhumathi et al., 2010).

15.5.1.2 Heteroglycans

Heteroglycans offer various potentials in the biomedical sector. Heteroglycans, namely pectins, agarose, alginates, gums, carrageenans, and glycosaminoglycans, are biodegradable, biocompatible, and possess unusual physicochemical properties, i.e., film/gel forming and thickening properties of electrostatic composites. The development of heteroglycan fibers in the nanometric range using electrospinning technology may be advantageous for drug delivery and also regenerative medicinal therapies (Lee et al., 2009).

Alginates

Alginates are long repeating-unit polysaccharides with varying concentrations of residues from D-mannuronic and L-guluronic acid that are (1-4)-linked. Due to their hemostatic qualities, alginate-based wound dressings are frequently applied on skin burns and exuding or bleeding wounds. Alginates such as calcium, calcium-sodium, collagen, and gelatin are extremely absorbent natural fiber dressing materials developed from processed algae.

Agar and agarose

Agar and agarose fibers are developed by wet-spinning technology and are mainly utilized in biomedical and biomaterial applications for wound healing. A solvent containing DMSO:water in a ratio of 9:1 was used to construct continuous fibers in an ethanol coagulation bath. Agarose fibers that were homogeneous and of smooth texture exhibited significant water-swelling capabilities of 400%–500% as well as tensile strength of 30–50 MPa. Agarose fibers have been shown to be superior for swelling in water than agar fibers. Meanwhile, agaropectin has been shown to have flexibility issues (Bao et al., 2010).

Carrageenan

Carrageenan or carrageenins are a family of natural linear polysaccharides that are extracted from red edible seaweeds. They offer several potentials in the pharmaceutical, biomaterial, and food industries for thickening, gelling, and stabilizing properties. PVP-KC hydrogels were created by subjecting a combination of water systems such as poly(N-vinyl-2-pyrrolidone), kappa-carrageenan (KC), potassium chloride, and PEG to various gamma radiation dosages. These hydrogels were evaluated on various factors such as

temperature, mechanical behavior, fluid uptake, swelling factor, pH, electrical conductivity, and bioadhesive property on the human skin to predict their potential in wound healing (Sen and Avcı, 2005).

15.5.2 Glycolipids

Glycolipids are the complex lipids comprising carbohydrates linked via a glycosidic bond. Their main qualities include providing stability to the cell membrane and enhancing cellular recognition, which is important in terms of cell immunity as it permits cells to form bonds to develop tissues. Patients suffering from skin burns and wounds can benefit from topical glycolipids therapy consisting of galactose liposomes because of the rapid uptake of neutrophils and macrophages. The ability of macrophages to release cytokines and growth factors promotes tissue remodeling and the repair mechanism which is a key approach to wound healing. When compared to a control group, an experiment on mutant mice using 1-3-galactosyl transferase revealed the beneficial response of −Gal liposome at a daily dose of 10 mg (Galili et al., 2010).

15.5.3 Proteoglycans

Proteoglycans are essential proteins, covalently linked with the glycosaminoglycan chain that have a significant amount of macromolecules in the composition of extracellular matrix. Neoproteoglycans are the most biocompatible and biodegradable synthetic glycoconjugates developed from essential nanomaterials, proteins, or polymers that are covalently linked to the glycosaminoglycan chain and connected with the cells and proteins. Conjugates such as protein glycosaminoglycan, nano-glycosaminoglycan, and polymer glycosaminoglycan complexes are the three basic forms of neoproteoglycan which possess in vivo and in vitro tissue-engineered applications (Weyers and Linhardt, 2013).

15.5.4 Proteins and peptides

15.5.4.1 Vegetal proteins

Vegetal proteins are proteins available naturally from plants. These include soya, pulses, seeds, certain grains etc. These foods contain all the amino acids in an acceptable quantity. The treatment of wounds and skin burns can also be aided by some vegetal proteins. An ex vivo study performed on excised skin of rat using a combinational biomaterial composite of soya protein and sago starch which was cross-linked with glutaraldehyde was

found to be effective in wound healing (Ramnath et al., 2012). Additionally, vegetal proteins such as soya and sodium caseinate-derived biomaterials offer significant advantages in wound healing and drug delivery due to their biocompatible and biodegradable natures (Silva et al., 2003).

15.5.4.2 Collagen

One of the most prevalent proteins found in the human body and skin is formed by fibroblasts and is known as collagen. Collagen offers several potential qualities such as enhanced wound-healing process at the cellular and molecular levels as well as aiding the development of new tissues and epithelialization of wounds. For the prevention and cure of partial/full-thickness wounds with low to high exudates, collagen dressings formulated from bovine, pig, or avian sources are mainly utilized. However, these dressings are avoided in severe skin burns and for the patients who are sensitive or allergic to these products (Murali et al., 2011). There have been many research works on the use of various collagen-based dressings and compositions for the treatment of wounds and burns, such as for deep wounds (collagen sponges), gingival wounds (collagen−glycosaminoglycan complex), oral wounds (resorbable collagen membrane), wound healing (DNA salmon−collagen film complex) (Shen et al., 2008), cutaneous wounds (collagen−minocycline hydrogels) (Ghica et al., 2011), skin grafting (collagen microfiber scaffolds) (Kempf et al., 2011for vascular grafts and wound repairing (collagen electrospun nanofiber scaffolds) (Fullana and Wnek, 2012), and modified collagen−alginic thermostable biopolymers for the treatment of wounds (Mitra et al., 2011).

Gelatin

Gelatin is a naturally available biopolymer mainly obtained from collagen, and also from various animal by-products. Nowadays, gelatin is mainly used in the pharmaceutical and biomedical industries for the development of drug-delivery applications and for wound healing due to its biocompatible and biodegradable dressings. To identify its healing properties, various gelatin-containing composition studies have been performed on the dorsal skin of rats, such as cross-linked gelatin-alginates, gelatin-hyaluronic acid sponges, and EGF-gelatin-based wound healing in conditions including excess tissue loss and nonhealed wounds, i.e., burns, diabetic foot ulcers, trauma, and static ulcers; bioresorbable gelatin films have also been used for the treatment of trauma and orthopedic injuries.

Keratin

The intermediary fibrin proteins present in vertebrate epithelia and corneous tissues such as hooves, horns, and claws are collectively referred to as keratin. Due to its potential to treat proteolytic injuries, keratin and its derivatives have been utilized in chronic wounds to speed up healing. Keratin-based novel wound dressings with optimum potential have demonstrated controlled release behavior of growth factors and antibiotics.

Silk fibroin

Silk fibrin offers exceptional characteristics in the wound-healing process such as adhesion, absorption of exudates as well as being biodegradable and biocompatible with less inflammatory responses. Additionally, silk fibroin is utilized for the management of skin grafts, artificial ligaments, tendons, etc. It also serves as an excellent candidate in regenerative medicinal therapies such as silk fibroin and chitosan complex scaffolds for tissue regeneration (Gobin et al., 2005), carbon nanotubes for wound healing, SF—alginate combinational sponges for full-thickness wounds, and SF film biomaterials for wound treatment (de Moraes and Beppu, 2013).

Bovine serum albumin (BSA)

BSA is a protein derived from cattle. Due to anionic charge, BSA act as an intermediate bridge between tissues and cells and also acts as a carrier to transport fatty acids, vitamins, hormones, etc. Because of its binding capabilities, it also acts as a scavenger for the removal of toxic material such as pyrogens from the medium. BSA nanofibers are developed from the globular proteins in BSA medium without utilizing any chemical cross-linkers. Because of the fibrous characteristic of BSA it possesses various benefits in wound healing, suturing, and wound closure. It is used in various biomedical and pharmaceutical applications due to its biocompatible, biodegradable, and effective mechanical qualities (Zhu et al., 2011).

Enzymes

Enzymes are proteins that offer several applications in wound healing. Proteolytic and fibrinolytic enzymes, along with collagenase and papain, are effectively utilized in the epithelialization of wounds. In pectin film applied for wound healing, the development of prostaglandin H was drastically enhanced (Dror et al., 2008). Lysostaphin, a cell lytic enzyme, was formulated as antiinfective bandages immobilized on electrospun fibers through a solution of cellulose, such as cellulose—chitosan and cellulose—

poly-methacrylate. However, enzymes are avoided in wound healing for patients affected by coagulation disorders (Miao et al., 2011).

15.5.5 Synthetic polymers

Synthetic polymers were developed chemically in laboratories, and are described as manmade polymers (Gobi et al., 2021). By increasing the mechanical and biocompatible potentials of individual components, synthetic and natural polymers can be used to create new kinds of materials.

A hydrophilic synthetic polymer, polyvinyl alcohol (PVA), is widely employed in a variety of biomedical applications (Gyles et al., 2017). PVA is possible due to the availability of hydroxyl molecules, which can help to form hydrogen bonds (Norouzi et al., 2021). Due to its poor hydrophilic properties, thick membrane, and inadequate flexibility, PVA is only occasionally used as a polymeric wound-dressing material (Venkataprasanna et al., 2020). A synthetic hydrophilic polymer is known as poly(ethylene glycol) (PEG) (Sahana and Rekha, 2018). Growth factors such as macromeres and epidermal growth factor are interlinked to each other through significant attraction. These can be used directly at the wound site. Mechanical, thermal, and PEG crystalline features are preserved by mixing polymer with chitosan and PLGA. Such PEG-based treatments are effective in diabetic wounds. These treatments speed up the healing process by promoting skin cell development, collagen deposition, and proliferation (Shahverdi et al., 2014). Methacrylic acid is a monomer used to develop the synthetic polymer known as poly(methacrylic acid) (PMAA). In order to merge bioactive compounds with carboxylic groups, such as drugs and inorganic nanoparticles, PMAA is highly recommended in biomedical applications due to its water-soluble and biocompatible nature (Lumbreras-Aguayo et al., 2019). This substances can alter noticeably in response to changes in the pH and iconic strength of the solution as well as having high swelling capabilities in water. N-vinylpyrrolidone (monomer) was used to develop a hydrophilic linear chain polymer known as polyvinylpyrrolidone (PVP) (Kausar, 2019). A lipophilic and semicrystalline synthetic polymer known as polycaprolactone (PCL) has significant crystalline and morphological properties (Mohamed and Yusoh, 2016). To enhance its mechanical capabilities, PCL has been formed by mixing with other polymers or combined with them. Another of the most widely utilized synthetic polymers in the biomedical sector is poly(lactic acid (PLA). Several other derivatives of PLA are available with its chiral structure, such as poly-L-lactide (PLLA) formed by L-polymerization and called L-lactide.

Electrospinning technology is the primary method to obtain synthetic polymers which have micropores and a highly specified surface area for the treatment of wounds and skin burns. Synthetic polymers for wound dressing offer occlusive or semiocclusive characteristics enabling them to act as a barrier to protect against the infiltration of microorganisms. They may be in the form of hydrogels, foams, or hydrocolloids. Exudates are entrapped by the polymer film which provides a moist environment to the wound. Various authors have developed synthetic polymer-based wound dressing materials, such as ciprofloxacin HCL-loaded polyurethane and dextran electrospun nanofiber. Carrageenan-hydrophilic polymer hydrogels, cellulose acetate, PLA, and PLGA infused with shikonin have been used for wound recovery due to their antimicrobial, antiinflammatory, and antitumor activities, in addition to PVP-based nanosilver alginate hydrogels. One study revealed that carboxy methyl-chitosan provides various in vitro and in vivo characteristics in wound healing, such as stimulation of fibroblasts and macrophages and the secretion of various cytokines.

15.6 Nanocomposites for wound healing

In the area of wound healing, an increasing number of novel nano-therapies have surfaced and are presently undergoing clinical research studies. Numerous nano tactics have been investigated focusing on various stages of wound repair, such as nanoparticles, nanocarriers, and nanomaterials. Nanoparticles (NPs) are one of the options that researchers are studying for wound healing due to their wide spectrum of antibacterial properties and quick efficiency with a minimum dose. Due to the inability to permit a cell barrier, conventional therapies for wound healing have limited success as compared to nanoparticles, which can permit entry effectively (Khan et al., 2019). Disruption of the cell membrane, changes to the genes, and inhibition of enzyme production are aspects of NPs' antimicrobial activity, which leads to cell apoptosis. In addition, nanomaterials (NMs) are smooth, flexible, and biocompatible wound-healing materials that act as a gas barrier, absorbent for exudates, and a shielding material against further damages or heat. There are two primary types of NMs used in wound healing: (1) NMs with inherent qualities useful for treating wounds and (2) NMs used as drug-delivery systems (Bhattacharya et al., 2019).

15.6.1 Nonpolymeric

There are several nonpolymeric NPs that are utilized in wound healing, including metal and metallic NPs, lipid NPs, and ceramic NPs, as discussed next.

15.6.1.1 Metal and metallic nanoparticles

Various metal-based NPs such as gold (AuNPs), copper (CuNPs), silver (AgNPs), zinc oxide (ZnO NPs), titanium dioxide (TiO_2), cerium oxide (CeO_2), yttrium oxide (Y_2O_3), and other metal-based NPs have been reported for their antibacterial and wound-healing properties. Silver has been used as a medicine for a very long time. For the management of open wounds, burns, and chronically infected wounds, many types of silver components, i.e., metallic silver, silver nitrate, and silver sulfadiazine are used currently (Rai et al., 2009). The use of AgNPs has recently drawn attention, particularly for the treatment of open wounds, as a result of the rise in pathogenic bacteria that are multidrug resistant and to reduce the use of antibiotics. Silver nanoparticles are the most researched nanomaterial of all nanoparticles because of their exceptional antibacterial properties. Silver NPs are more effective at demonstrating higher antibacterial property than traditional therapies because they have a large surface area to volume ratio, which improves their interaction with microbes. The phosphorus-containing compounds in microbial cells, such as DNA ,can also bind with silver NPs, as can sulfur-containing proteins anchored in bacterial membranes.

A study performed by Orlowski and co-workers formulated tannic acid modified silver NPs possessing higher antibacterial action against *P. aeruginosa* and *E. coli*. The data revealed that the prepared NPs showed better wound closure, formation of granulating tissues, and angiogenesis in a mouse wound model (Orlowski et al., 2018). Another study performed by Peng and co-workers developed CS-coated silver NPs. Their data showed that the prepared formulation possessed excellent biocompatibility and was effective against meticillin-resistant *S. aureus* in contrast to polyvinyl-coated silver NPs (Peng et al., 2017). Silver NPs with CS polyethylene glycol hydrogel have been produced as a treatment for diabetic chronic wounds (Masood et al., 2019).

15.6.1.2 Lipid nanoparticles

Researchers and scientists have become interested in lipid-based NPs recently due to their potential use as drug-delivery systems. In addition, lipid NPs can be modified to suit certain health issues and routes of administration. These systems are risk-free, economical, and provide protection to drugs from biological deterioration. Due to their minimal toxicity and excellent efficacy, lipid NPs are employed as drug-delivery carriers in sensitive tissues (Attama et al., 2012). Such lipid NPs include solid lipid nanoparticles (SLNs), nanostructured lipid carriers (NLCs) and drug−lipid conjugates.

In addition to reducing pain and infection, essential oil offers several properties in wound healing such as an antibacterial, relaxing, and quick recovery from wounds (Saporito et al., 2018). Although rosemary and eucalyptus leaf extract have the ability to heal wounds, these essential oil are naturally volatile and are rapidly broken down by oxidation, heat, light, and volatilization (Apostolides et al., 2013). Hence, SLN- and NLC-based carriers are employed that enclose these essential oils and maintain their biological activity (Gokce et al., 2012). A study by Saporito and co-workers (Saporito et al., 2018) developed eucalyptus and rosemary oil-loaded NLCs. They used coco butter and olive oil as solid and liquid lipids which possess higher natural stability, biocompatibility, and rapid wound-healing properties through dermal fibroblasts. This study revealed that the prepared formulation effectively provided higher healing and antimicrobial properties showing a synergistic effect between olive oil and eucalyptus oil.

15.6.1.3 Ceramic nanoparticles

Ceramic NPs represent one of the most commonly employed inorganic NPs for wound healing. These NPs are mostly known for their wound healing, tissue regeneration, and antibacterial properties (Urie et al., 2018). Nanohydroxyapatite and calcium triphosphate as ceramic NPs offer broad applications in drug delivery and wound healing processes. the sol—gel formulation method is generally used for the development of ceramic NPs. Furthermore, these NPs are extensively utilized in the development of tissue-engineered formulations. Various authors has revealed the potential of ceramic NPs, such as Deepthi and co-workers who described the use of ceramic-CS-based NPs for bone rejuvenation (Deepthi et al., 2016). When combined with CS, components such as hydroxyapatite, silicon dioxide, bioglass ceramic, titanium dioxide, and zirconium oxide formed nanoscaffolds that are very effective in regenerating bone. To cure bone abnormalities in traditional therapies, artificial materials were implanted surgically, although this had several negative side effects. Hence, ceramic nanoparticles are employed to clear the way for tissue regeneration to overcome these problems. A bioactive ceramics and bioresorbable polymer mixture creates an extracellular matrix for the healing of bone tissue.

15.6.2 Polymeric nanoparticles

In the current era, strategies for the treatment of chronic wounds have been developed to deliver drugs and biomolecules in bioresorbable polymeric NPs with controlled release, such as PLGA, alginate, gelatin, chitosan,

PEG, and polycaprolactones. Polymeric NPs avoid frequent dosing, extend the therapeutic effectiveness, and provide controlled drug delivery in wound healing (Masood, 2016).

15.6.2.1 Synthetic

PLGA offers one of the most widely used synthetic polymers due to its biodegradability, biocompatibility, hydrophobic property, and for entrapping the growth factor in chronic wound therapy among all polymeric NPs. It offers sustained drug release through NPs because it absorbs less water and enhances the degradation time (Masood, 2016). Additionally, the breakdown of PLGA yields lactate, which promotes pro-COL factors, angiogenesis, and the recruitment of endothelial cells to the wound site. A combinational therapy of PLGA—curcumin NPs revealed a twofold higher potential in wound healing than PLGA and curcumin alone.

Polyurethane is utilized to develop the bioresorbable polyester known as polycaprolactone (PCL). It is well known for its controlled intracellular reabsorption mechanism and its cell-specific responsiveness. In contrast to various available synthetic polymers, it is simple to use and can form a variety of nanostructures, including scaffolds and micro- and nano-carriers (Guarino et al., 2002). The antibacterial, antimicrobial, and wound-healing properties of PCL have been illustrated in numerous investigations to be enhanced by their combination with any metal or metal-based NPs. One study conducted on a skin model using zinc NPs which were developed by electrospun polycaprolactone provided scar-free wound healing by enhancing fibroblast proliferation (Augustine et al., 2014).

15.6.2.2 Natural

Chitosan (CS) is available from the shells of crustaceans and is made up of N-acetyl-D-glucosamine and randomly dispersed D-glucosamine. CS offers numerous potential in wound-healing applications, such as biodegradability, biocompatibility, cellular binding capacity, wound healing, etc. (Li et al., 2012). The study performed by Piran and co-workers developed electrospun PCL nanoscaffolds loaded with chitosan. The effect of the CS NPs scaffold topography and drug release behavior on skin fibroblasts has been investigated (Piran et al., 2018). Another prominent natural polymer used in wound healing is alginate, which is found in the cell wall of brown algae and which possesses maximum scaffold capacity. A study by Liao and co-workers developed porous alginate hydrogels. These hydrogels contains PCL, PEG, and calcium gluconate crystals which are effectively deposited

in the pores of microspheres. The data revealed that the prepared hydrogel effectively enhanced the growth of fibroblasts, which led to providing new areas for skin tissue engineering (Liao et al., 2018).

15.6.3 Hydrogels

Hydrogels are among the most prevalent wound-healing systems because they trap moisture at the wound surface, develop an optimum environment for healing, and keep the skin hydrated. They are easily formulated and also allow prolonged drug release. Chitosan, fibrin, hyaluronic acid, or synthetic polymer, either as cellulose compounds or poloxamers, can be used to make hydrogels. These hydrogels are able to create a cool and moist environment that promotes the wound-healing process as well as water vapor permeability and inhibiting microorganisms from entering the wound.

A study performed by Khorasani and co-workers developed a CS-ZnO-PVA-based hydrogel which progressively enhanced the antibacterial properties without any cellular toxicity (Khorasani et al., 2018). Another study performed by Hsu and co-workers developed gel-based adipose-derived stem cell hydrogels for the treatment of wounds. This in vivo study revealed enhanced wound healing on both mouse and porcine skin models (Hsu et al., 2019).

15.6.4 Nanofibers

Nanofibers (NFs) are the key nanomaterial utilized for the wound-healing process. NFs have a diameter of 10−100 nm and a large specific surface area (Abrigo et al., 2014). They are formulated using the process of electro-spinning technology, where various polymer solutions are processed into nanometric fibers using electric force. These fibers have the capability to create a porous network forming a mesh. Due to the tough network and higher surface area to volume ratio, NFs are suitable candidates to use as scaffolds. They can be synthesized from natural or synthetic polymers as well as carbon-based and semiconductor materials. These fibers are renowned for their use in biological sensing, wound dressing, drug delivery, and tissue engineering formulations along with regenerative drug therapies (Chen et al., 2017).

A study by Kandhasamy and co-workers developed a nanofiber scaffold using COL-coated ostholamide for wound treatment. The prepared formulation possessed excellent mechanical characteristic and antimicrobial property against *P. aeruginosa* and *S. aureus*. The prepared system offers

controlled delivery of ostholamide and provides stability against enzymatic degradation. In another study, a PLGA-aloe vera gel-growth factor scaffold was formed by electrospinning technology. In vivo studies on a mice model showed excellent wound-healing properties by reducing the inflammation (Garcia-Orue et al., 2017).

15.7 Conclusion and future perspectives

In pharmaceutical and biomedical applications, bioresorbable polymers offer excellent potential. Bioresorbable polymers for wound healing must be mechanically strong, have good antibacterial activity, and have hemostatic, water vapor permeability, appropriate gas exchange as well as higher free radical scavenging properties. Such characteristics can enhance the wound-healing process. Additionally, the dressing should be easy to remove after healing and should be nontoxic, biocompatible, nonallergic, biostable, and biodegradable. Natural and synthetic bioresorbable polymers offer their own advantages while treating wound. Many researchers and scientists have proved the capabilities of such polymers by encapsulating them in nanocomposites such as nanoparticles, nanocarriers, hydrogels, metal and metal oxide components, etc. for tissue regeneration, and healing of skin burns and wounds, particularly using in vitro models. Wound healing has attracted the attention of many researchers as it is difficult to treat chronic wounds. The market is constantly expanding, driven by the rise in the number of patients globally, requiring new tactics and materials. Polymer- and hydrogel-based dressings make up the majority of competitive technologies available today for advanced wound care. Advanced dressings typically serve a purpose beyond merely concealing and covering wounds. By using the bioactive qualities of polymers, it is feasible to speed up tissue remodeling and regeneration, improving skin conditions while minimizing the appearance or size of any associated scars.

Despite the broad variety of solutions already in the market, bioresorbable dressings have a low impact on the healing of complex and chronic wounds, although they remain essential components of acute wound care. Recently, enormous progress has been made in our understanding of the molecular mechanisms underlying wound healing, and we may now use this expertise to create novel therapeutic strategies for nonhealing wounds. Also, employing natural resources can effectively overcome these issues. Tissue engineering techniques use 3D hybrid scaffolds which are both synthetic and natural that interact with human cells

effectively. The possible advantages of this strategy include the capacity to increase the in vivo properties which enhance bone formation, reducing donor site morbidity, shortening the surgical time, and decreasing the technical difficulty of the repair. A 3D reconstruction will significantly reduce the amount of time needed for healing. Additionally, it ensures optimal contact between the graft and the recipient site for better integration. Another benefit is increased permeability with particular hybrid materials, which is essential for tissue remodelling and replacement. As a result, the blood can easily flow through the graft's internal chambers without any resistance. Hence, because of such tactics, the healing process is significantly enhanced because of cell attachments.

16.1 Introduction to bioresorbable polymers

Bioresorbable polymers are a category of polymers that experience metabolic degradation within the human body upon implantation. They include polylactide (PLA), polyglycolide (PGA), and copolymers of PLA/PGA. These polymers can be modified to attain specific mechanical properties and degradation, making them suitable for medical applications such as drug delivery, resorbable screws, anchors, etc. (Implantable Formulations, 1499).

Bioresorbable polymers are synthetic polymers which can be broken down (Fig. 16.1) into nontoxic elements and eliminated through natural metabolic pathways from the body. They have gained remarkable attention aimed at wound-healing applications due to their biocompatibility and

biodegradability. Nevertheless, bioresorbable polymers often exhibit lower mechanical properties and drug delivery capability for optimal wound healing compared to the requirements (Khot et al., 2021). To overcome these obstacles, researchers have recently discovered bioresorbable polymer/halloysite nanotube (HNT) blend composite wound dressings, which have good mechanical strength and improved drug delivery, and also enhanced antibacterial activity (Khot et al., 2021).

The bioresorbable polymers in the context of medicine could be a diversifying event regarding biomaterials. Biomaterials have the capability to restore function, related to joint replacement, fixation of fracture-related devices and dental or canal root implants, etc.; the success rates of biomaterials vary significantly and range from excellent in full replacement of the hip area to less successful rates of other types of body joints and parts; therefore biomaterials used in devices are being improved through a greater understanding of the related consequences [The National Institutes of Health (NIH) Consensus Development Program, 1982]. Recent research shows that the demand for bioresorbable polymer implants is growing continuously because of their biodegradability and unconventional implants ability in several applications according to duration of utilization for weeks to months as per the necessity (McKeen, 2014). However, the benefits of bioabsorbable implants have been improved in recent decades; mostly implants are produced using synthetic materials which results in problems related to toxicity and chronic inflammatory reactions, which can effectively be reduced through the use of natural materials (Pertici, 2017).

16.1.1 Properties of bioresorbable polymers

Bioresorbable polymers can also be understood as biodegradable or absorbable polymers as they are polymers that break down and can be absorbed by the body over time. They have shown significant interest in medical-related applications, including drug delivery, tissue reengineering, and implantable medical devices (Gleadall, 2015). Some of the highly desirable and noted properties of bioresorbable polymers are listed here.

(i) Biocompatibility: Bioresorbable polymers have been designed to be biocompatible, which ensures that they are nontoxic and do not cause an immune response when introduced into the body (Ulery et al., 2011).

(ii) Biodegradability: These polymers having the advantage of being broken down into smaller components size at the micro level over time through a process called hydrolysis. The degradation products

are typically water and carbon dioxide, which are naturally acting and occurring substances inside the body (Nanda et al., 2022).

(iii) Mechanical properties: The properties relevant to the mechanical strength of bioresorbable polymers usually vary and are dependent on the particular type of polymer used. They can be developed to produce varieties related to stiffness, elasticity, and strength which are suitable to be used in various applications (Alhanish and Ali, 2023).

(iv) Processing: Injection molding, solvent casting, and electrospinning are most common techniques associated with bioresorbable polymers processing (Casalini and Perale, 2012).

(v) Rate of degradation: Absorption of bioresorbable polymers depends on several factors such as body type, body condition, body parts, etc., and thus the degradation behavior also varies according to the polymer used, and the size and shape of the device (Pappalardo et al., 2019).

(vi) Biostability: This refers to the period of time during which any bioresorbable polymer product functions efficiently and maintains its mechanical properties until it finally begins to degrade (Wang and Wang, 2012).

Bioresorbable polymers are typically biocompatible and do not cause any harm to the body, although a few studies have suggested that the degradation products may cause inflammation in some cases. Meanwhile, the properties related to bioresorbable polymers make them very impressive and attractive materials for use in medical applications. However, care and serious consideration must be observed in the specific type of polymer used and the implantation site to ensure the maximum possible performance and safety (Deng et al., 2023).

16.1.2 Applications of bioresorbable polymers

Bioresorbable polymers have huge possibilities to be used in medical applications due to their ability to degrade or be absorbed within the body over time. Some widely used applications of bioresorbable polymers are listed here:

(i) Drug delivery: Bioresorbable polymers are employed for their targeted drug-delivery capability within the human body over a prolonged duration. They have been designed to degrade at an optimum time to control the release of drugs (Fig. 16.2).

(ii) Tissue reengineering: Bioresorbable polymers can be used to reengineer new tissue developments. These recreated products/scaffolds have to be

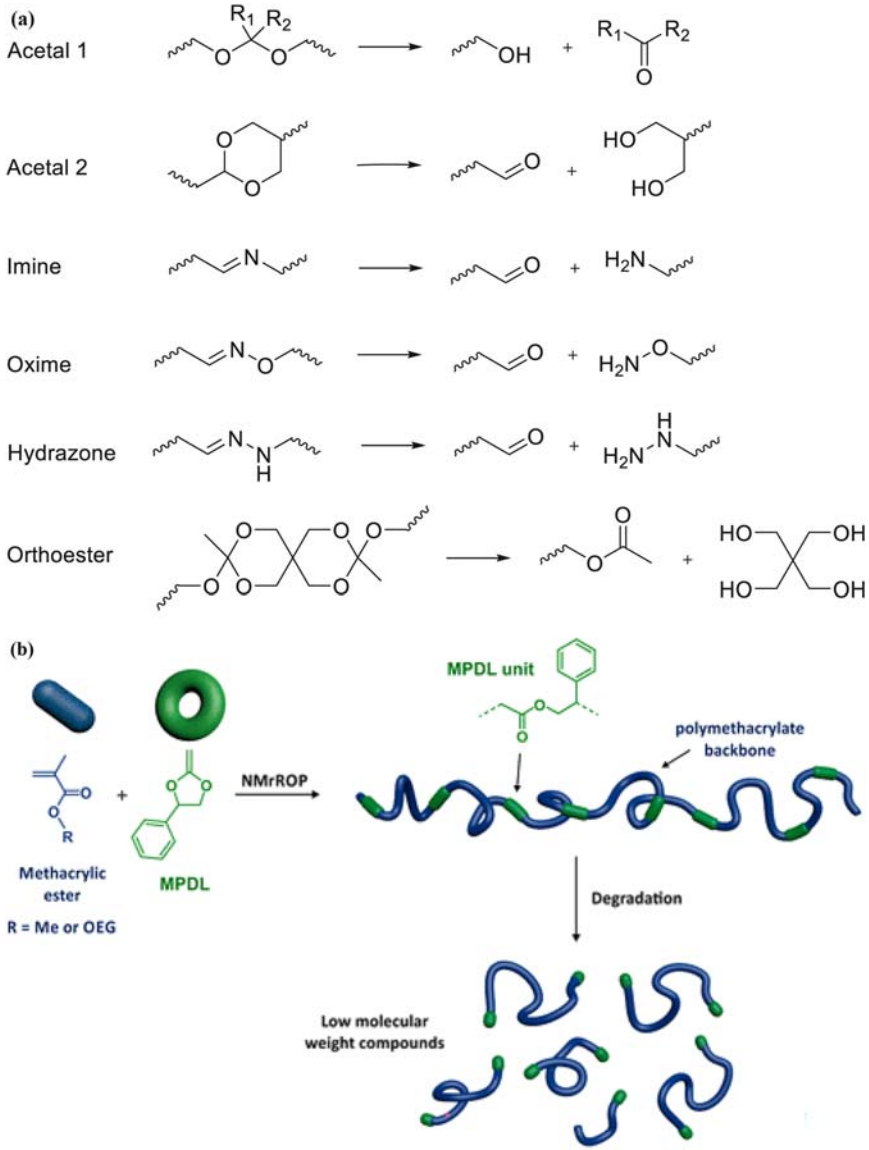

Figure 16.2 (a) Degradable functions and hydrolysis of common acids in an acidic aqueous atmosphere, (b) blending the degradable copolymers using nitroxide-mediated radical ring-opening copolymerization (NMrROP) with methacrylic esters and 2-methylene-4-phenyl-1,3-dioxolane (MPDL) as an ester-bound precursor incorporated into the copolymer backbone. *(Reproduced with permission from Rust et al. (2023).)*

implanted in the body and allow it to degrade according to a predefined time frame through behaving like functional tissue (Socci et al., 2023).

(iii) Surgical sutures: Bioresorbable polymers are used to develop surgical sutures which will break down over time, which eliminates any suture removal requirements and associated risk of infection (Afewerki et al., 2023).

(iv) Implants: Bioresorbable polymers are being used to create body part implants that degrade over a certain time period and are absorbed by the body. The main examples include screws, plates, and pins which have been used to repair fractured bones (Abbas et al., 2021; Bioresorbable Polymers Market to Expand, 2023).

(v) Stents: Advanced bioresorbable polymers are being used to develop stents that are inserted into blood vessels to allow smooth blood flow in the treatment of narrowed or blocked arteries and which degrades over time (Kim et al., 2021).

(vi) Wound dressings: Bioresorbable polymers can be used to develop wound dressings which will promote the healing capacity and be absorbed by the body over a predefined time frame (Nguyen et al., 2023).

The acceptable or desirable applications of bioresorbable polymers are having a wide range of opportunities therefore, it is yet to be explored for new materials development along with new fabrication processes inventions. The capability to self-degrade or be absorbed within the body heralds a demanding unconventional opportunity toward the traditional approach to permanent implants and devices, as it will reduce the risk of associated long-term medical complications and the need for additional surgeries.

16.2 Classifications of bioresorbable polymers

Bioresorbable polymers, also known as biodegradable polymers, belong to a category of polymers that undergo natural degradation processes in the body, resulting in harmless compounds (Hajebi et al., 2021). These polymers can be classified based on their chemical structure and origin.

Natural polymers: The polymers which are obtained from natural origins are called natural polymers (Fig. 16.3).

Examples include: animal, plant, or microbial origin, such as collagen, gelatin, chitosan, starch, and cellulose.

Synthetic polymers: Those polymers are developed or synthesized chemically in research laboratories are called synthetic polymers (Dirauf et al., 2022).

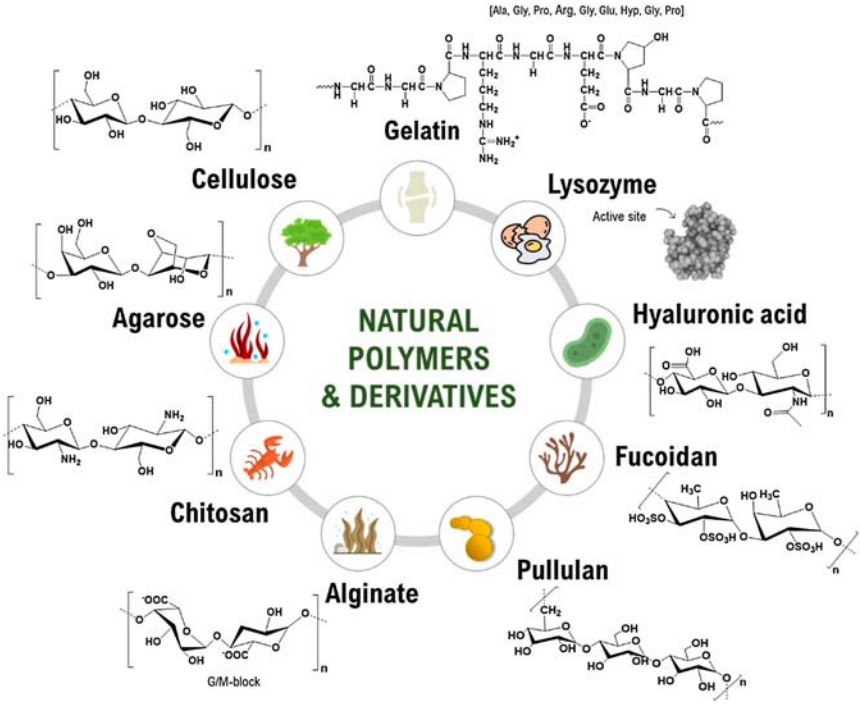

Figure 16.3 Examples of naturally available polymers with their potential derivatives. *(Reproduced with permission from Silva et al. (2021).)*

Examples include: PLA, PGA, polycaprolactone (PCL), and their co-polymers, etc.

Hybrid polymers: The polymers which are made by conjoining natural and synthetic polymers are called hybrid polymers (Zhiraslanovna Ozkan et al., 2018).

Examples include: silk fibroin and chitosan blends, collagen—PLA blends, and gelatin—PCL blends, etc.

Inorganic polymers: The polymers which are fabricated by inorganic elements such as silicon, phosphorus, and calcium are called inorganic polymers.

Examples include: bioactive glass and hydroxyapatite, etc.

Protein-based polymers: The polymers which are derived through proteins such as elastin, collagen, and silk are called protein-based polymers. These polymers are biocompatible and can also be broken down by enzymes in the body (Fig. 16.4).

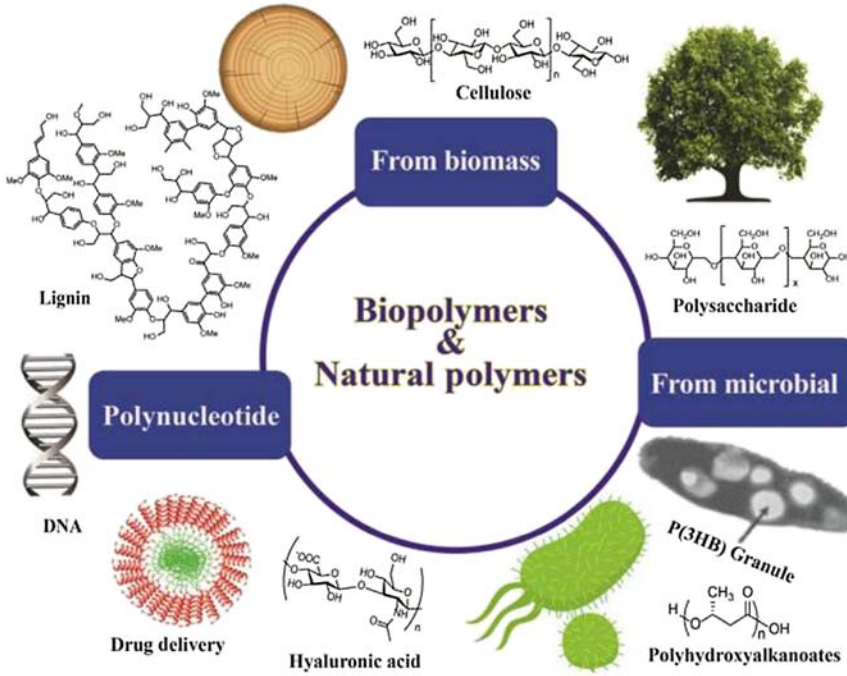

Figure 16.4 Some selective biopolymers with their classifications. *(Reproduced with permission from Alaswad et al. (2022).)*

16.3 Halloysite nanotubes

Halloysite nanotubes (HNTs) have gained major consideration in recent years due to their excellent properties (Table 16.1) and favorable applications. HNTs are tubular nanomaterials composed of hydrated aluminosilicate clay, characterized by an inner diameter of approximately 10−30 nm (Fig. 16.5), an outer diameter of 40−70 nm, and a length ranging between 200 and 2000 nm (Abdullayev and Lvov, 2013; Pereira et al., 2021).

16.3.1 Properties of HNTs

- **Biocompatibility**: HNTs exhibit the capability to be biocompatible which makes them favorable for biomedical applications (Lvov and Abdullayev, 2013).
- **High aspect ratio**: HNTs typically possess a high aspect ratio, meaning a higher ratio of surface area to volume. This characteristic makes HNTs an ideal choice for medical applications due to properties such as adsorption and catalysis (Wu et al., 2019).

Table 16.1 Common analytical data regarding HNTs for the fabrication of polymer nanocomposites.

HNT composition	$Al_2Si_2O_5(OH)_4 \cdot nH_2O$
HNT outer diameter	40–70 nm
HNT mean particle size in aqueous solution	143 nm
HNT pore space	14%–46.8%
HNT inner diameter	10–40 nm
HNT aspect ratio (L/D)	10–50
HNT length	0.2–2 μm
HNT density	2.14–2.59 g/cm^3
HNT particle size range in aqueous solution	50–400 nm
HNT lumen space	11%–39%
HNT average pore size	79.7–100.2 Å
HNT elastic modulus (theoretical value)	140 GPa (230–340 GPa)
HNT BET surface area	22.1–81.6 m^2/g
HNT structural water release temperature	400–600°C

Adapted with permission from Liu et al. (2014).

- **Thermal stability**: HNTs are thermally very stable and have a high melting point, thus making them highly suitable for high-temperature applications (Du et al., 2010).
- **Chemical stability**: HNTs are very chemically stable thus they have high demand in the field of drug deliveries and as reinforcement materials in polymer composites (Ganapathy et al., 2022).

16.3.2 Applications of HNTs

- **Drug delivery**: The utilization of HNTs in pharmaceuticals is in high demand because of their wide surface area and potential porosity (Guo et al., 2019; Santos et al., 2018).
- **Catalysis**: High aspect ratio and chemically stable properties increase HNT capability to be used as catalysis (Lvov et al., 2016a; Barman et al., 2020).
- **Reinforcement material**: HNTs have the capability to function as a reinforcing material in polymer composites, aiming to enhance their mechanical properties (Namathoti and Vakkalagadda, 2023).
- **Environmental remediation**: HNTs are helpful in controlling pollution due to their ability to adsorb pollutants and heavy metals from the atmosphere (Li et al., 2022).
- **Cosmetics development**: HNTs have been found to be suitable for use as cosmetics ingredients as natural fillers or adsorbents (Suh, 2015).

(2014).)*

16.4 Bioresorbable polymer-based HNT composites

Bioresorbable polymer-based HNT composites are an emerging area of research in nanomaterials development because of their ability to deliver the collective advantages of both HNTs and bioresorbable polymers. This ability appeals to their usability in several fields, such as biomedical products, drug deliveries, and tissue reengineering (Asghari et al., 2017). The integration of HNTs into bioresorbable polymer matrix would expand their mechanical, thermal, and biological characteristics. HNTs as a reinforcement material would enrich the stiffness, strength, and toughness of the polymer matrix (Cheng et al., 2020a). Numerous bioresorbable

polymers have recently been used to develop HNT- based composites, for example, poly-lactic acid, poly-glycolic acid, and poly-caprolactone. These composite-based investigations have revealed favorable outcomes in terms of mechanical properties, bio-medicine, and biodegradability. Research has shown that HNT and N,N′-ethylenebis (stearamide) in a weight ratio of 2.33:1, respectively, in a polymethylmethacrylate matrix improved the properties related to scratch resistance, mechanical properties, and the dispersion of nanoparticles in the matrix without losing other properties (Vuluga et al., 2018). Encapsulated aspirin drug into the HNT lumen in a weight ratio of 1:1 and 2:1 (HNTs/aspirin) was reinforced to the PLA matrix, and the results revealed that aspirin in a 1:1 ratio could be successfully loaded in the HNT lumen with successive release of aspirin from the nanocomposite as well as the addition of HNT increasing the mechanical properties which also aids in use HNT as a drug-eluting agent (Venkatesh et al., 2019).

16.5 Mechanical properties of HNT-reinforced polymer blends

The mechanical properties of polymer blends reinforced with HNTs are influenced by various factors, such as the type and quantity of polymer used, aspect ratio of HNTs, concentration of HNTs, and the processing techniques employed (Gaaz et al., 2017). The literature has evidenced that fabricated nanocomposite by the ultrasonification dispersion technique for HNT reinforced in five proportions (0, 1, 2, 3, and 4 by weight%) to lapox L-12 epoxy matrix delivered increased mechanical properties with the best mechanical properties found at 3 wt.% of HNT reinforcement which also revealed that properties can be modified by the filler present and the dispersion condition alteration (Ravichandran et al., 2019). A Takayanagi model-based research study on determining the modulus of HNT polymer nanocomposites evidenced that HNT reinforcement is not suitable for polymers for an HNT volume fraction and interphase depth less than 0.01 and 5 nm, respectively, although 2.88 relative modulus was found at the 0.04 proportion of HNT volume and at 20 nm interphase depth, which indicates that the lower values of the associated matrix modulus and degradation initiation are appropriate to reinforce, while a higher polymer's modulus results in poor strengthening and affects the system modulus significantly (Zare and Rhee, 2022). In this context, the mechanical properties of some nanocomposites are discussed in Table 16.2.

Table 16.2 The influence of variations in hexadecyl-tri-methyl-ammonium-bromide (HEDA), silane, and urea on the mechanical properties of HNT/polypropylene nanocomposites.

Blend composition	σ_b (MPa)	E (MPa)
Neat polypropylene	36.3 ± 0.4	1340 ± 45
Polypropylene + 5 wt.% untreated halloysite nanotubes	36.5 ± 0.4	1440 ± 84
Polypropylene + 5 wt.% halloysite nanotubes modified HEDA	36.5 ± 0.3	1547 ± 35
Polypropylene + 5 wt.% halloysite nanotubes modified silane	36.2 ± 0.6	1495 ± 65
Polypropylene + 5 wt.% halloysite nanotubes modified urea	36.5 ± 0.8	1449 ± 30

Adapted with permission from Khunova et al. (2013).

The higher aspect ratio of HNTs supports its high suitability for reinforcement in the polymer matrix. HNT integration into the polymer matrix may improve the properties related to mechanical strength. The consequences of HNT concentration over the mechanical strength of HNT-reinforced polymer nanocomposites have been examined and concluded that increasing the HNT concentration results in increased stiffness along with improved strength of the nanocomposite. Conversely, a higher concentration of HNTs can result in clustering, negatively affecting the mechanical properties of the nanocomposite. The impact of HNT concentration on mechanical properties is discussed in detail in Table 16.3.

The type of polymer used in the blend also has a significant impact on the mechanical properties calculation related to the composite and as evidenced by literature that PLA–HNT composites exhibit higher stiffness and strength than polyethylene glycol (PEG)–HNT composites (Naser et al., 2021; Nedaipour et al., 2020; Cavallaro et al., 2013). Processing methods also influence the properties of HNT–polymer blends as it has been observed that the solvent casting method can deliver more uniform dispersion of the NTs, leading to improved mechanical properties (Guo et al., 2009; Modesti et al., 2005; Esawi et al., 2010).

16.6 Antibacterial activity of HNT–polymer blends

Incorporating HNTs into polymer blends can enhance the antibacterial activity of the composite due to the integral antibacterial properties of

Table 16.3 Mean values of Young's modulus (E), yield stress (σ_Y), ultimate stress (σ_{break}), and elongation at break (ϵ_{break}) are reported for various concentrations of high-density polyethylene (HDPE)/halloysite nanotubes nanocomposites, and also for pure HDPE (Cecílio et al., 2023).

Specimen	HNT content (wt.%)	E (MPa)	σ_Y (MPa)	σ_{break} (MPa)	ϵ_{break} (%)
High-density polyethylene	0	415 ± 12	18.5 ± 0.4	40 ± 2	840 ± 50
[Halloysite nanotubes]−[methylaluminoxane (MAO)]-N5	5	440 ± 15	14.0 ± 0.5	28 ± 2	600 ± 60
[Halloysite nanotubes]−[methylaluminoxane] -N8	8	450 ± 18	15.0 ± 0.5	38 ± 4	740 ± 50
[Halloysite nanotubes]−[methylaluminoxane] -N15	15	475 ± 20	15.5 ± 0.6	43 ± 4	930 ± 60
[Halloysite nanotubes]−[methylaluminoxane] -N23	23	515 ± 20	17.0 ± 0.7	33 ± 4	770 ± 70
[Halloysite nanotubes]−[supported activator (SA)]-N5	5	555 ± 20	18.5 ± 0.5	41 ± 1	670 ± 40
[Halloysite nanotubes]−[supported activator]-N9	9	605 ± 20	19.0 ± 0.5	44 ± 1	730 ± 40
Halloysite nanotubes −[supported activator]-N16	16	680 ± 20	20.5 ± 0.8	44 ± 2	910 ± 60
Halloysite nanotubes−[supported activator]-N20	20	710 ± 25	20.5 ± 0.8	36 ± 3	840 ± 40

HNTs. A high aspect ratio of HNTs allows for interaction with bacterial cells, leading to disruption of their cell membrane and subsequent bacterial death. The concentration and aspect ratio of HNTs can affect their antibacterial activity. A research study on erythromycin (ERY)−HNT-reinforced polycaprolactone (PCL) matrix composite developed by the electrospinning method evaluated the antibacterial action on a sterile zone in place of poly-caprolactone nanofibers holding 7.0 wt.% halloysite nanotubes/erythromycin (Fig. 16.6) when used against *Escherichia coli* and *Staphylococcus aureus* bacteria (Table 16.4); an additional improvement of the mechanical properties was also accomplished (Khunová et al., 2022).

An investigation reported on developed nanocomposites of polydimethylsiloxane (PDMS)−halloysite nanotubes by solvent swelling (Table 16.5) and revealed that these nanocomposites have great potential for use as a coating over antibacterial invasive devices to prevent possible infections as the polydimethylsiloxane−HNT nanocomposite showed improved performance over commercial catheters at preventing bacterial growth (Fig. 16.7) and also revealed that a higher concentration of HNTs in the composite leads to higher antibacterial activity (Boyer et al., 2018).

16.7 Drug-delivery capacity of HNT−polymer blends

HNTs possess a higher aspect ratio and porosity, which supports their suitability for drug-delivery applications (Ahuja and Pathak, 2009). The incorporation of HNTs into polymer blends can enhance the drug-delivery capacity of the composite, and numerous researchers have investigated the applicability of HNT−polymer blends in regard to drug-delivery applications (Hasani et al., 2021). A drug-delivery system responsive to H_2O_2 was developed by integrating a hydrogel (based on halloysite) using the coprecipitation method, which exhibits a "turn-on" fluorescence characteristic upon exposure to H_2O_2. The investigation results revealed that the hydrogel initiated fragmentation when in contact with H_2O_2, with subsequent degradation ongoing, and in that way a responsive drug was released (Fig. 16.8). The drug discharge were increased at ($[H_2O_2] = 0.02\ \mu M$) physiological concentration, whereas more than 90% drug was released at ($[H_2O_2] = 200\ \mu M$) pathological concentration. Therefore, HNTs can be loaded for countless drug types and the drug discharge can be well-ordered by changing the HNT concentration. HNTs work as a reservoir for the drug and provide sustained discharge over time, leading to improved therapeutic efficacy (Cheng et al., 2020b).

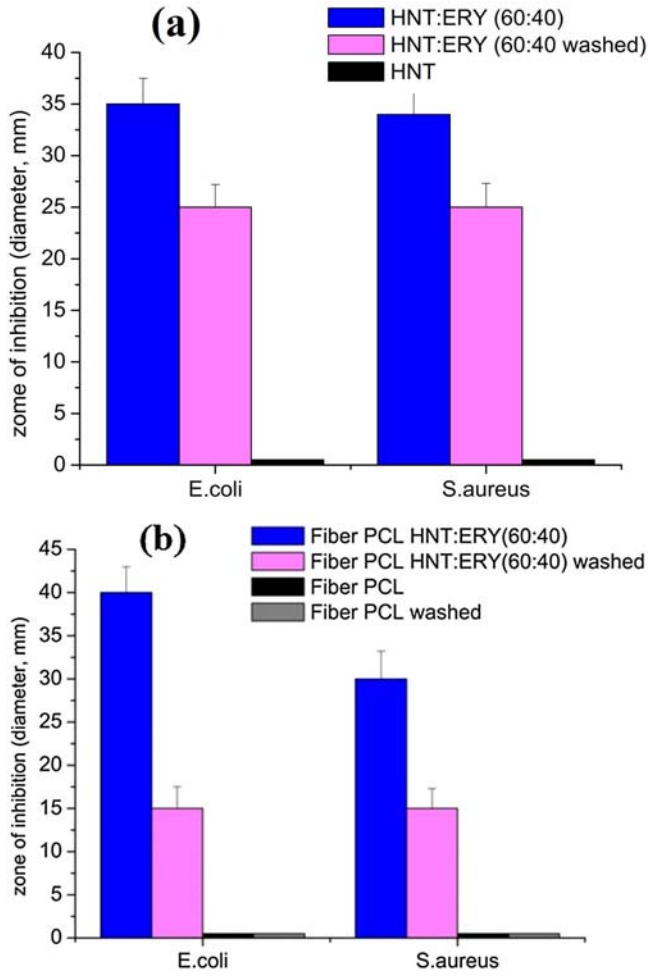

Figure 16.6 Disk diffusion-based examination of *Escherichia coli* and *Staphylococcus aureus* for the antibacterial effect of (a) halloysite nanotubes (HNTs) loaded with erythromycin, both before and after removing erythromycin from the external surface of HNTs, which was evaluated by measuring the inhibition zone diameter ± SE (standard error). (b) The antibacterial activity of poly-capro-lactone (PCL)/halloysite nanotube (HNT) fibers, with and without washing, and containing erythromycin was assessed by measuring the inhibition zone diameter ± SE (standard error) (Khunová et al., 2022).

HNTs have been investigated for their safe utilization and have been found to be relatively harmless for the human body and to prevent bacterial cell cultures in vivo (Lvov et al., 2016b). In this context, a related study of nanocomposites fabricated with chitosan−HNTs to deliver the drug

Drug loading of diclofenac has been confirmed on HNT nanotubes after XRD examination, while an FTIR report also illustrated the encapsulation of the drug (Paul et al., 2022). A discussion of loaded drugs with HNTs and the loading method is provided in Table 16.6.

Table 16.6 Utilization of halloysite nanotubes in drug delivery.

Drug	HNT and modifier	Advantages	Drug loading (wt.%)	Site of drug loading	Release rate (wt.%/mg g^{-1} h^{-1})	Release kinetics model	Application
Diclofenac sodium	Sodium alginate/ hydroxyapatite/ halloysite nanotube nanocomposite hydrogel beads	Cumulative discharge behavior	74.63 ± 1.65	Lumen	9.19 mg g^{-1} h^{-1}	–	Controlled drug delivery
Ibuprofen	APTES-modified HNT	Gradual release attributed to the robust electrostatic interaction and affinity	14.8	Lumen and partially on outer surface	–	Korsmeyer –Peppas model	Controlled discharge of drug
Aspirin	APTES modified or natural halloysite nanotubes	Enhanced loading capacity for aspirin	11.98	Lumen pores	–	Higuchi kinetic model	Controlled release of drug
Amoxicillin, brilliant green, chlorhexidine doxycycline, gentamicin sulfate, iodine, and potassium clavulanate	Halloysite nanotubes–PCL scaffolds	Promoters of structural integrity Suppression of bacterial growth	–	Lumen	–	–	Sutures and surgical dressings

16.8 Wound dressings based on HNT–polymer blends

Wound dressings include the constituents that contain ingredients that protect a wound, and can include a barrier to pathogens. Usually, the wound dressing should have suitable biodegradability to speed up the healing process in addition to preventing any threats related to infections and bacterial invasion (O'Donnell and Lau, 2006). Wound dressings are part of the wound care process to ensure healing. HNT composites can be used in wound dressing development due to their antibacterial capability, biocompatibility, and drug-carrying properties. Wound dressings can broadly be classified into two system, namely primary and secondary dressings. The first layer directly surrounds the wound area and is the primary wound dressing, while successive covering up of the primary dressing layer is known as secondary dressing (Stoica et al., 2020). Wound dressings can be categorized into four main types based on their applications: traditional passive dressings, skin substitutes, interactive artificial dressings, and bioactive dressings (Fig. 16.9) (Ndlovu et al., 2021).

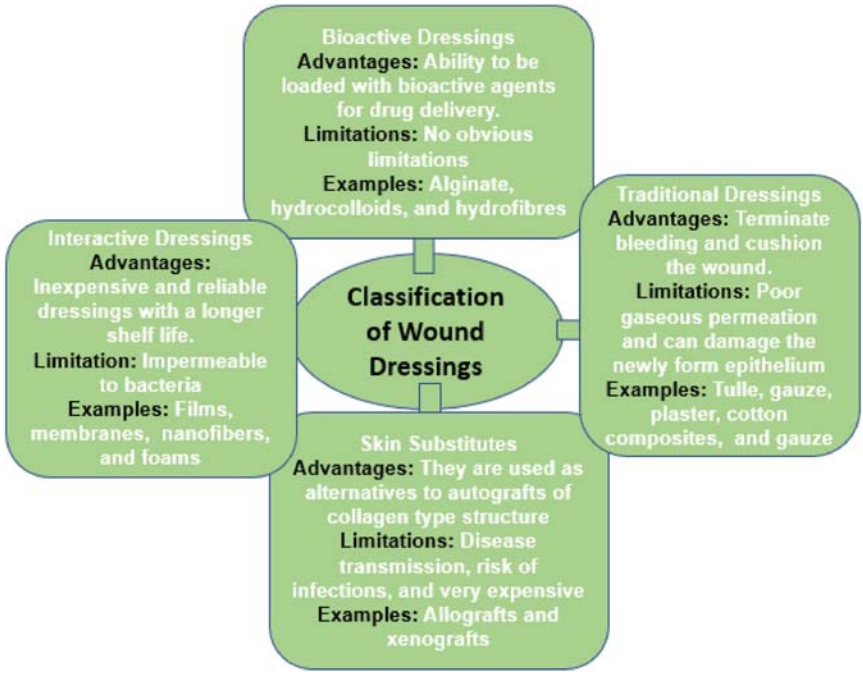

Figure 16.9 Wound dressing classifications. *(Reproduced with permission from Ndlovu et al. (2021).)*

The incorporation of HNTs into polymer blends can be a good option for wound dressing and healing processes (Fig. 16.10). A study on burn wound healing explored the use of a nanocomposite consisting of minocycline and APTES surface-modified HNTs to reinforce a PVA coating for wound dressing. The nanocomposites were thoroughly characterized using techniques such as FTIR, scanning electron microscopy (SEM), X-ray diffraction (XRD), zeta potential analysis, TGA, and field emission scanning electron microscopy (FESEM). Additionally, antibacterial tests and water absorption assessments were conducted to further examine the properties of the nanocomposites. The results revealed a tubular structure with uniformly distributed halloysite nanotubes and minocycline, along with sustained drug releasing, biodegradability and good water absorption capacity (Fig. 16.11) were observed, which is also apt for dealing with wound secretions to prevent infection. Minocycline incorporation with HNT-PVA showed enhanced antibacterial effects to Gram-positive and Gram-negative bacteria. This investigation supports HNT-PVA nanocomposite use regarding wound dressings for open or highly possibly infected wounds. The degradation rate of nanocomposite against the

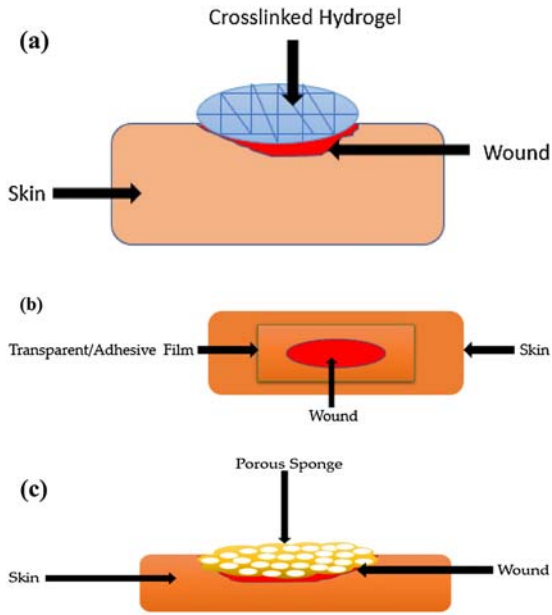

Figure 16.10 (a) Cross-linked hydrogel on skin wound, (b) utilization of transparent film dressing for skin wounds, (c) use of microporous sponge for skin wound treatment. *(Reproduced with permission from Ndlovu et al. (2021).)*

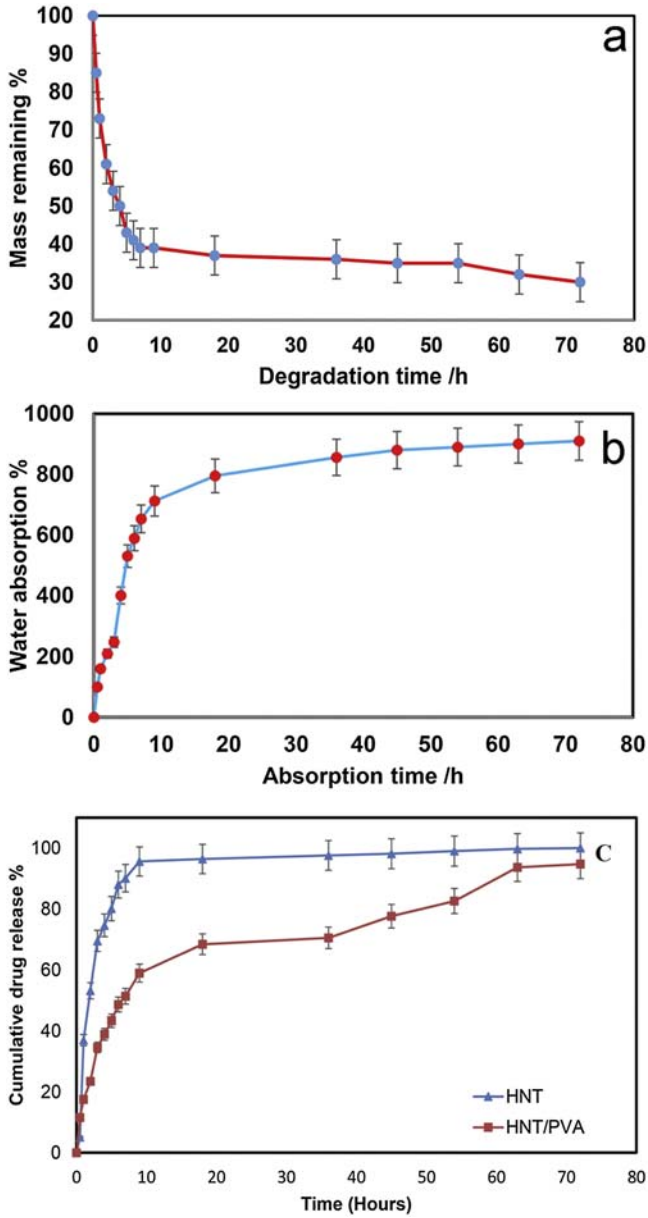

Figure 16.11 (a) Mass loss degradation (b) water absorption of halloysite nanotubes/PVA/minocycline nanocomposite in phosphate buffer saline, (c) in vitro drug discharge profile of halloysite nanotubes and halloysite nanotubes/PVA. *(Reproduced with permission from Mohebali et al. (2020).)*

absorption time can be seen in Fig. 16.9. Rapid degradation, for 8 h, shows the release of minocycline, whereas between 8 and 10 h breaking of polymer chains and sustained drug release occur for the next 3 days without much weight loss, which means that the proposed wound dressing could sustain its erection for up to a maximum of 3 days (Mohebali et al., 2020).

Therefore, HNT–polymer nanocomposites could be useful in wound dressing development, including films, fibers, hydrogels, etc. HNT–polymer-based wound dressings may deliver several benefits related to moisture retention, antibacterial activity, and as a drug carrier. Wound dressing is a part of tissue repair which means that wound healing can be considered as tissue reengineering (Cialdai et al., 2017; Wilkinson and Hardman, 2020). A study on wound dressing for skin healing for astronauts or skin injuries associated with space mission programs has been reported. The HNTs and thymol (Thy) integrated with poly 2-hydroxyethyl methacrylate (pHEMA) for developing nanocomposites further examined the chemical–physical properties to ensure Thy-HNT lumen integration and healing capacity because thymol accumulated with natural healing ingredients in addition to the drug release rate. The results revealed that the maximum swelling ability for 90 mg of dried sponge was 5.5 mg of Thy along with 62% of charged Thymol released in over a 1-week duration which indicated controlled drug release, and the calculation of efficiency in respect of drug released was calculated as follows (Zagni et al., 2023):

$$\text{Drug release efficiency } (\%) = \frac{\text{Mass released drug}}{\text{Mass loaded drug}} \times 100$$

Growth in cryogel swelling (Fig. 16.12) would support the burst effect which is very desirable in wound healing as a sustained release of drug prevents bacteria formation and infections (Fig. 16.13).

A nanocomposite sponge based on natural substances was developed to address injuries associated with the liver and tail of rats. This was achieved by combining carboxymethyl chitosan (CMC), sericin–silver nanoparticles (Ser-Ag), and halloysite nanotubes (Fig. 16.14). Different amounts of HNT powder (0.5, 1, and 2 g) were separately mixed with silver nitrate powder (8.5 mg) and a sericin solution (50 mL or approximately 0.1%). The resulting solutions (50 mL each) were then mixed with a carboxymethyl chitosan (CMC) solution (approximately 6%) to create the nanocomposite samples called CMC/Ser-Ag/HNT1, CMC/Ser-Ag/HNT2, and CMC/Ser-Ag/HNT4, as shown in Fig. 16.15. The investigation revealed that the

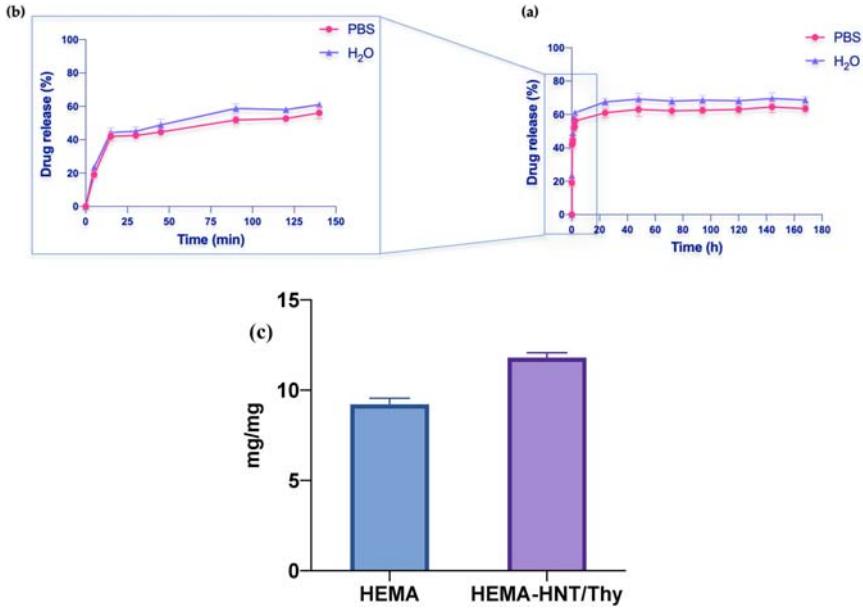

Figure 16.12 (a) Thymol release (%) from nanocomposite (hydroxyethyl methacrylate-HNT/thymol) within 1 week. (b) growth of thymol release (%) in the first 140 min. (c) Swelling capacity of hydroxyethyl-methacrylate and HEMA-HNT/thymol cryogels. *(Reproduced with permission from Zagni et al. (2023).)*

integration of HNTs into the CMC sponge resulted in a mechanical compressive strength of 100 kPa. Meanwhile, the hemostatic capacity (hemostasis time) was observed to be 15 ± 3 s and 12 ± 3 s in liver and caudal injuries, respectively. The sericin–silver nanoparticles (Ser-Ag) were found to be effective against bacteria such as *Escherichia coli* and *Staphylococcus aureus*. Additionally, experiments conducted on a full-thickness skin defect and injury model in rats confirmed the ability of the CMC/Ser-Ag/HNT4-based sponge to promote epithelialization and collagen formation. Immuno-fluorescence (IF) staining analyses revealed acceptable effectiveness for inflammation reduction after downregulating the expression of interleukin-6 (IL-6) along with improved angiogenesis after upregulating vascular endothelial growth factor (Li et al., 2023).

Ideally, achieving low cytotoxicity is important for promoting effective wound healing (Hao et al., 2022). In the case of the CMC/Ser-Ag/HNT4 group, minimal differences in cell survival were observed compared with the control group, and a low hemolysis rate (less than 5%) was observed, indicating low cytotoxicity and good hemo-compatibility

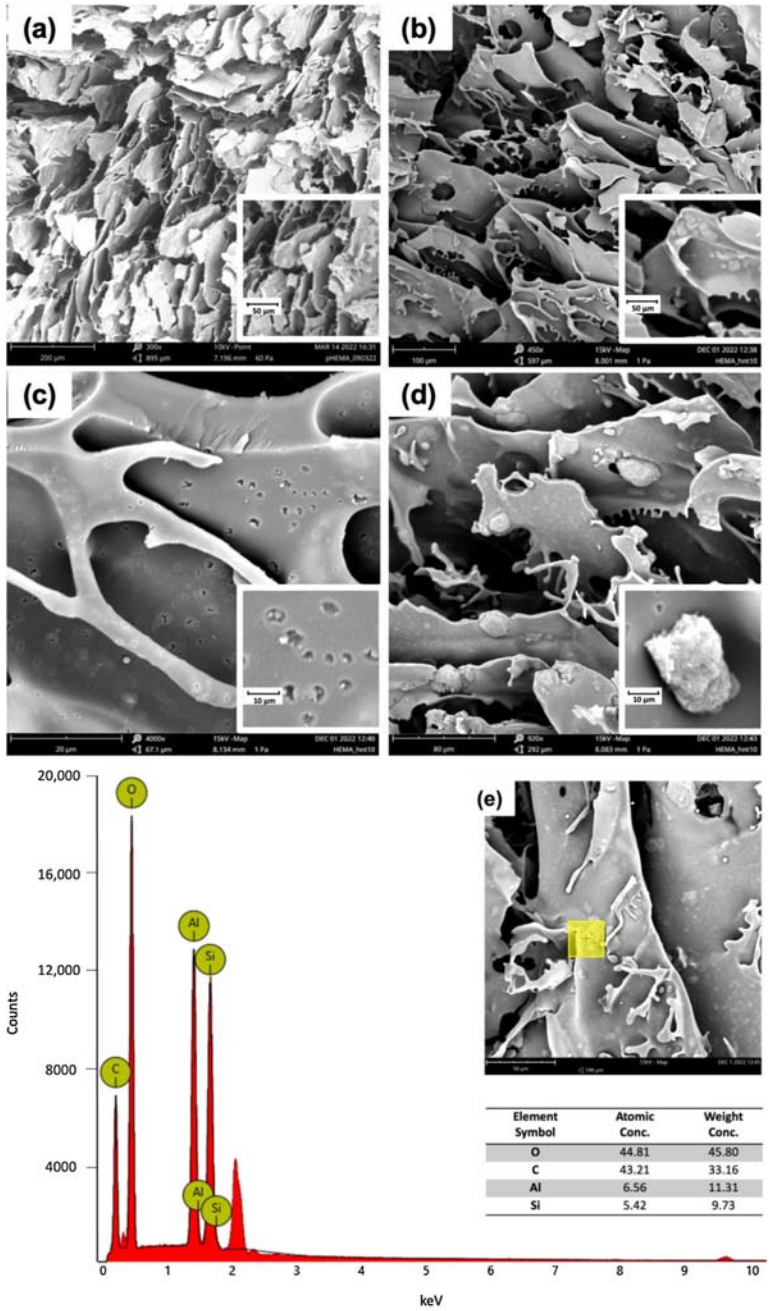

Figure 16.13 Scanning electron microscopy (SEM) images were captured to examine various samples, including: (a) cryogel of hydroxyethyl-methacrylate, (b) cryogel of hydroxyethyl-methacrylate with HNT/thymol, (c) inclusion of HNTs, (d) aggregates of halloysite, (e) energy-dispersive X-ray spectroscopy (EDX) analysis was performed on a selected area (indicated by a yellow square) of the hydroxyethyl-methacrylate with HNT/thymol cryogel. It is noteworthy that the presence of unlabeled peaks at 2.1 and 9.6 keV corresponds to gold, which was used to enhance conductivity during the examination. *(Reproduced with permission from Zagni et al. (2023).)*

(Chin et al., 2019; Wen et al., 2016). Effective control of bleeding is a crucial and desirable property of wound dressings, which is evidenced by the CMC/Ser-Ag/HNT4 sponge's high hemostatic effect (Udangawa et al., 2019; Yu et al., 2019a). Additionally, the CMC/Ser-Ag/HNT4 sponge has shown promising results in terms of timely bleeding control, antibacterial capability, and wound infection healing capability, as evidenced by a rat model of full-thickness skin defect wound healing (Matoori et al., 2021; Yu et al., 2019b). The CMC/Ser-Ag/HNT4 sponge has also shown the ability to promote the formation of newly created collagen fibers in wounds, which is favorable for wound healing (Chen et al., 2021).

An alginate-based wound dressing with vancomycin over the HNTs revealed that the release of vancomycin from gel is sustained with the integration of gelatin as compared to the incorporation of silica. The three samples were included in the research with the incorporation of vancomycin to HNTs, hydrochloric acid-activated HNTs (HNT-HCL), and 3-aminopropyl-trimethoxysilane-modified HNTs (HNT-APTS), respectively. However, the integration of gelatin in alginate gels is good for slowing the vancomycin-HNT-APTS drug release but resulted in poor antibacterial activity. On the other hand, encapsulated vancomycin-HNTs-APTS in alginate gel without gelatin showed good results in drug release capability and against microbacteria, which makes it a potential wound dressing material for treatment (Kurczewska et al., 2017).

Another study suggested that microfibrous mats have excellent biocompatibility along with sustained antimicrobial protection. The mat was prepared via the electrospinning method with tetracycline hydrochloride (TCH) loaded to the HNTs with regenerated silk fibroin (RSF) (Wu et al., 2021). Many more applications are available regarding HNT−polymer composite wound dressings, and some are included in Table 16.7.

16.9 Challenges and limitations of HNT−polymer blends

Despite the encouraging properties of HNTs and HNT−polymer blends, there are also some challenges and restrictions that require careful attention. The primary challenge is to succeed in uniform HNT distribution in the polymer. The agglomeration or random distribution of ingredients in the nanocomposite can have a significant impact on its mechanical, thermal, and optical properties. Modified HNTs' surface/structure could be an alternative to overcoming this challenge, but better optimization is

Table 16.7 HNT/polymer nanocomposite applications for wound healing.

Polymer composites	Drugs loading	Type of wound dressing/ healing
Poly(lactic-co-glycolic acid) (PLGA)	Tetracycline hydrochloride	Electrospun nanofiber mats
Poly(lactic-co-glycolic acid), chitosan	Amoxicillin	Electrospun nanofiber mats
Polyvinyl alcohol	Minocycline	Film
Cellulose ether, polyvinyl alcohol	Gentamicin sulfate	Electrospun nanofiber mats
PCL	Brilliant green, amoxicillin, and potassium clavulanate	Electrospun nanofiber mats
PCL, gelatin	NA	Electrospun nanofiber mats
Gelatin	Ciprofloxacin and polymyxin B sulfate	Film
Carrageenan	NA	Film
Chitosan	Doxorubicin	Hydrogel mold
Chitosan	NA	Sponges
Gelatin, sericin	Zinc and copper ions	Electrospun nanofiber mats
Poly(lactic-co-glycolic acid), chitosan	Minocycline	Film

necessary before this. Another challenge is the probable toxicity of HNTs. Although HNTs are generally considered biocompatible and nontoxic, using them in medical areas for a long time raises some concerns in a few cases. HNTs and the related drug's size, aspect ratio, and surface modification variation can affect the toxicity as per the available research reports. The cost and compatibility of polymers to HNTs are other considerable challenges that have been seen because HNTs are new in nanocomposites and thus the availability of HNTs and the best suitable polymer to incorporate with HNTs need to be explore.

16.10 Future prospects of HNT–polymer blends in biomedical applications

The excellent properties of HNT–polymer blends place HNT composites as a favorable material for biomedical engineering and medical applications.

There is an increasing necessity for modernization in tissue reengineering by HNT incorporation. HNT–polymer composites have exhibited great potential in creating scaffolds that reproduce the natural extracellular matrix, providing a suitable environment for cell growth and tissue regeneration. The higher aspect ratio and porosity characteristics of HNTs support and enhance the cell adhesion and production, resulting in enhanced tissue regeneration naturally. Improving the drug-loading capability for a variety of drugs would support safer cancer treatment in the future through HNT–polymers.

16.11 Conclusion

HNT-based composites have exhibited potential positive results for wound dressings and wound care applications. The integration of HNTs with bioresorbable polymer matrices exhibited significant enhancements in drug delivery and antibacterial activities. HNTs have a tubular structure with a higher aspect ratio, which supports their drug-loading capability and controlled release of drugs. Alteration of the synthesis methods enables control over the properties of HNTs, polymers, and composites for medical purposes. The biodegradability of HNT composites exhibits suitable degradation rates, gradual absorption, and elimination from the body. These characteristics reduce the repeated requirement for dressing removal, resulting in better patient comfort and wound care management. Further optimization of the blending process, achieving reliable dispersion of HNTs, and improving stability are desirable.

CHAPTER 17

Biobehavioral structure, elastic, optical, and thermoluminescence properties of $Al_xCa_{y-x}Nd_{01}P_{70}$ bioglasses

Ravi Kumar Guntu
Department of Physics, Sreenidhi Institute of Science and Technology, JNT University, Hyderabad, Telangana, India

17.1 Introduction

Well-known calcio-phosphates and their derivatives, such as calcio-orthophosphates, $Ca(PO_2)_4$, are used for a variety of biomedical applications, including bio-bones and implants (Jeong et al., 2019). On the other hand, calcio-phosphate glass of Nd^{3+} ions has been widely recognized for various photonic or white LED semiconducting applications (Flórez et al., 2009). Researchers have been looking for highly effective radiative-capable, highly elastic optical, and biocompatible materials for the past 20 years, up until the present (Guntu, 2020). By using optical and biocompatible procedures, the $Al_xCa_{y-x}Nd_{01}P_{70}$ materials were created and described in this way (Wang et al., 2021). It is generally known that white light applications require Nd^{3+} ions to have a desirable wavelength of 1.06 μm. In this manner, Nd_2O_3 is selected to improve optical phenomena in calcio-phosphate glasses (Guntu, 2020). For many industrial and opto-biomedical applications, Nd_2O_3-doped calcio-phosphate glasses are the most important glassy matrices (Pugliese et al., 2020).

The best options for dental and optical replacements are made of phosphate glass, which is currently used extensively in biomedical technology (Islam et al., 2017). As a result of the solid-state (diode-pumped) laser technology's recent, quick advancement, advanced improvements in unique class laser resources have achieved considerable prominence (Brauch et al., 2022). Lasing evaluations owing to Nd^{3+} ions ($\lambda \sim 1.06$ μm) are

Bioresorbable Polymers and their Composites

often helpful and meet practical needs. In order to achieve the desired properties for a successful implementation of high gain, the host material must be chosen appropriately. The prepared Nd_2O_3-doped P_2O_5 composite glasses are then thoroughly examined in the current work for their suitability for LED applications (Burtan-Gwizdala et al., 2023). Phosphate glasses usually have interdependent, amorphous structures and exhibit glass characteristics when heated to their melting point (Calahoo and Wondraczek, 2020). When it comes to opto-electronic and biomedical applications, P_2O_5 glasses are often dependable and known for their extensive creative and evolving use. Due to their strong optically stimulated luminescence, phosphate glasses with Al_2O_3 doping are typically utilized as dosimeters in radiation therapy and protection applications (Hirosawa et al., 2021). The development of a flexible, high-elastic bio-implant has drawn a great deal of interest due to its potential uses in areas including bio-bone, and also for uses that require its high elasticity and biocompatibility. $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses may be most helpful in this area to create noncorrosive, flexible, highly efficient, and biocompatible materials that are radiative competent materials (Anil Kumar et al., 2021). Finding an appropriate glass matrix with excellent glass-forming ability, and optical and biocompatible qualities thus has become a research hotspot in the disciplines of optical and biomedical applications.

17.2 Methods and measurements

Glass samples were prepared using the melt quenching process. The quantified chemical composition, i.e., $Al_xCa_{y-x}Nd_{01}P_{70}$, was chosen for present synthesis, where "x" varies as 0, 3, 5, 8, and 10 mol%, and $y = 29$ mol%. The following is a list of the detailed chemical composition.

$$\mathbf{A_0}\ 00Al_2O_3 + 29\ CaF_2 + 01\ Nd_2O_3 + 70\ P_2O_5$$

$$\mathbf{A_3}\ 03Al_2O_3 + 26\ CaF_2 + 01\ Nd_2O_3 + 70\ P_2O_5$$

$$\mathbf{A_5}\ 05Al_2O_3 + 24\ CaF_2 + 01\ Nd_2O_3 + 70\ P_2O_5$$

$$\mathbf{A_8}\ 08Al_2O_3 + 21\ CaF_2 + 01\ Nd_2O_3 + 70\ P_2O_5$$

$$\mathbf{A_{10}}\ 10Al_2O_3 + 19\ CaF_2 + 01\ Nd_2O_3 + 70\ P_2O_5$$

Agate mortar is used to mix AR grade 99% (Sigma Aldrich) pure chemicals, such as Nd_2O_3, CaF_2, Al_2O_3, and P_2O_5, in the appropriate

mol%. The necessary chemical ratios were fully combined using an agate mortar and then liquefied over the course of 30 min at a temperature of 1265°C in a silica crucible using an automatic programmed furnace. The prepared melt was discharged into a brass cast, and the samples were annealed in a muffle furnace that ran at a temperature of around 415°C. Measurements of prepared glass are dimensionally improved for both structural (thickness $\geq$0.5 cm, both length and breadth $\geq$1 cm) and optical (thickness = 0.2 cm, both length and breadth = 1 cm) characterization. All of the existing characterizations were completed with the following tools. Both weight and density were measured using a Scale Tech digital weighing scale (weighing capacity: 0–250 g; precision: 10^{-4} gm/cm^3). The XRD measurements were conducted using a Shimadzu XRD-7000, X-ray diffractometer (range: 0–80°C; precision: 0.1°C). Surface morphology and chemical analysis studies were conducted using the Hitachi S 3700N (precision: ±1 μm; range: 1–200 μm). Elastic measurements were performed using a WT-311D ultrasonic flaw detector (precision: 0.1°C; range: 0–80°C). For pH measurements, a Manti MT-101 (pH range: 0–14; precision: 0.1 pH) was employed. For DTA measurements, a Hitachi DTG-60 H (range: 27–1200°C; precision: 1°C) was employed. TL measurements were performed using a 137 cesium irradiation source and a Nucleonix TL/OSL Reader (range: 27–550°C; precision: 1°C). MAC OS Version 10.15.1 based 2.3 MAT Laband 2019 MAC Office software was used to plot all the figures.

17.3 Results and discussion

17.3.1 Structural studies

Fig. 17.1 reports $Al_xCa_{y-x}Nd_{01}P_{70}$ materials. Fig. 17.2 reports X-ray diffraction analysis of $Al_xCa_{y-x}Nd_{01}P_{70}$ materials. Chemical analyses of

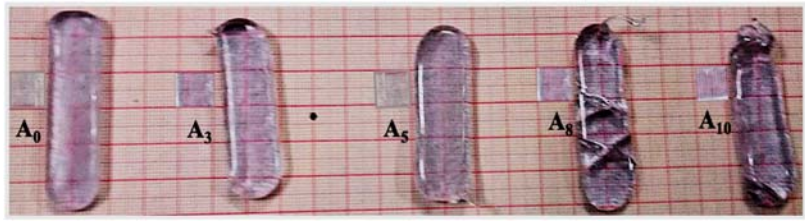

Figure 17.1 $Al_xCa_{y-x}Nd_{01}P_{70}$ glass materials, where, '*x*' varies as 0, 3, 5, 8 and 10 mol%; $y = 29$ mol%.

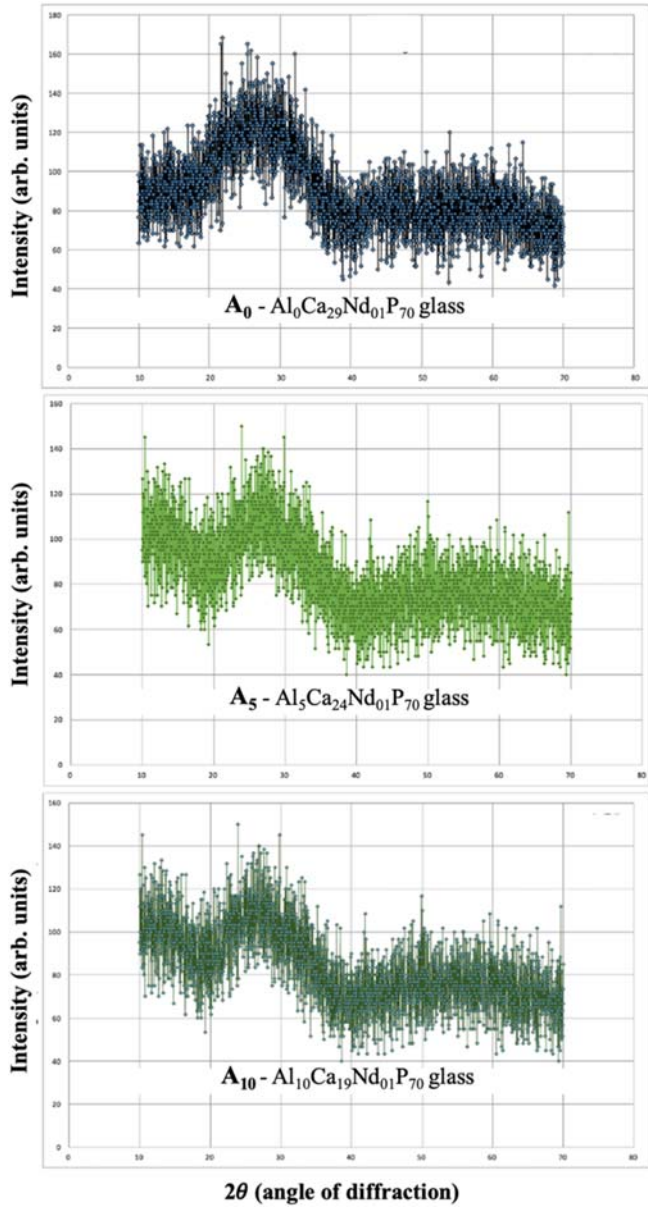

Figure 17.2 X-ray diffraction analysis of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses. The diffraction angles are taken up to an accuracy of ± 0.1 degree.

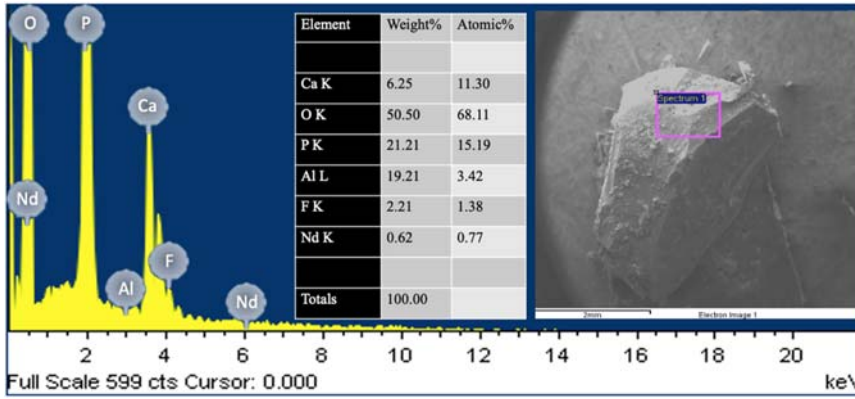

Figure 17.3 Chemical analysis of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses. Inset of the figure reports the surface morphology of sample A_5 recorded with 2 mm resolution.

$Al_xCa_{y-x}Nd_{01}P_{70}$ materials are shown in Fig. 17.3. The inset of the figure reports the surface morphology of sample code A_5. The results drawn from the X-ray diffraction reports reveal that the glass tests prepared are purely glassy (noncrystalline).

The evaluations of density and refractive index increase up to 5 mol% of Al_2O_3 concentration, however, the evaluations of molar volume follow an entirely different trend. Density was determined using the Archimedes method. Additional research was done on elastic characteristics including elastic modulus and microhardness of current glass testing. Microhardness (H) grades are ranked in the same order as Young's (Y) modulus assessments up to a concentration of 5 mol% Al_2O_3. Table 17.1 depicts both the physical and elastic parameter evolutions (Ravi Kumar, 2019). The evolution of the physical and elastic properties of the current glass series of tests were calculated using the following equations (Montoya-Quesada et al., 2020):

$$L = \rho V_L^2, \eta = \rho V_S^2, Y = (1+\sigma)2\eta, K = L - \frac{4}{3\eta}, \sigma = \frac{(L-2\eta)}{2(L-\eta)} \;\&$$

$$H = Y\frac{(1-2\sigma)}{6(1+\sigma)};$$

Fig. 17.4 illustrates the FT-IR spectra of $Al_xCa_{y-x}Nd_{01}P_{70}$ materials. All the absorbances at different wavenumber ranges suggest Ca-O (1410 cm^{-1}) units, phosphorus (1250, 1070 and 875 cm^{-1}) units, aluminum (710 and 440 cm^{-1}) octa- and tetrahedral units, and Nd-O (630 cm^{-1}) vibrations

Table 17.1 Summary of the elastic, thermal stability, optical, and thermoluminescence properties of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses.

Physical, elastic, and thermal stability analysis

(Gui et al., 2019; Guntu, 2019). DTA thermograms of existing glass materials are presented in Fig. 17.5. The evolutions of thermal stability are determined from DTA spectra and the values are observed to be decreasing with increasing concentration of Al_2O_3 up to 5 mol%. Phosphate glass nature of the present kind is quite different from the conduct of either pure phosphate or borate glass materials (Rajagukguk et al., 2019). Fig. 17.6 presents the structural analyses of existing glasses (Rama Krishna Chand et al., 2022). For the most part, the phosphate is a brief glass having PO_4 tetrahedron key units, and these units are interconnected through their corner sharing. The addition of Al_2O_3 to the phosphate cross-linkages and their tetrahedral units are made with Al_2O_3 chains supporting the P—O—Al linkages. Al_2O_3 is clearly not a straight glass at any rate in the case of a modernizer like CaF_2 as it gets into contact in the glass with both octahedral (AlO_6) and (AlO_4) tetrahedral units (Zhang and Liu, 2018).

The addition of calcium fluoride and alumina trioxide to existing phosphate glasses will liberate nonbridging oxygens. When Al_2O_3 is incorporated into phosphate glasses, the charge is exchanged for tetrahedral AlO_4 units. When the phosphate chains depolymerize and the pyramidal AlO_4 units withdraw, Al-O-Al connections are forced to form (Dimitriadis et al., 2020). The low magnitude of NBOs that were caused by variations in

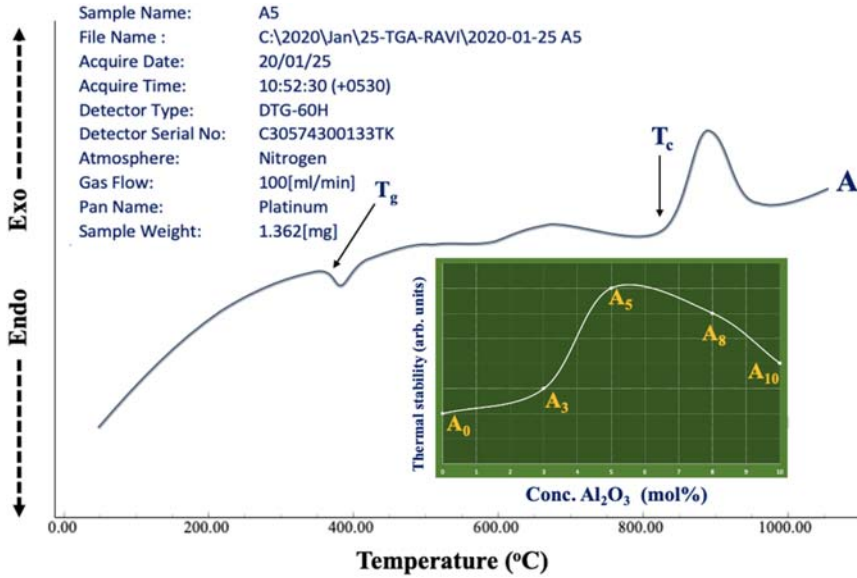

Figure 17.5 DTA spectrum of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses. Inset represents variation in thermal stability with Al_2O_3 concentration. The temperatures are taken up to an accuracy of ± 1°C.

the concentration of Al_2O_3 in the existing glass materials are affected by the addition of Nd_2O_3 to existing Al_2O_3 calcium phosphate glasses.

17.3.2 Thermoluminescence studies

Fig. 17.7 reports the thermoluminescence (TL) analysis (temperature ~ 27–375°C under 0, 15, and 30 min of γ-irradiation) of the present glasses. Existing glasses' TL glow curve intensities were shown to rise with increasing Al_2O_3 concentrations up to 5 mol%. The following are the formulae (Ravi Kumar, 2019; Guntu et al., 2020) that were utilized to determine the trap depth characteristics of preexisting glass samples:

$$E_\tau = C_\tau\left(\frac{KT_m^2}{\tau}\right) - b_\tau(2KT_m); E_\delta = C_\delta\left(\frac{KT_m^2}{\delta}\right) - b_\delta(2KT_m);$$

$$E_\omega = C_\omega\left(\frac{KT_m^2}{\omega}\right) - b_\omega(2KT_m);$$

where,

$$\tau = T_m - T_1; \delta = T_2 - T_m; \omega = T_2 - T_1;$$

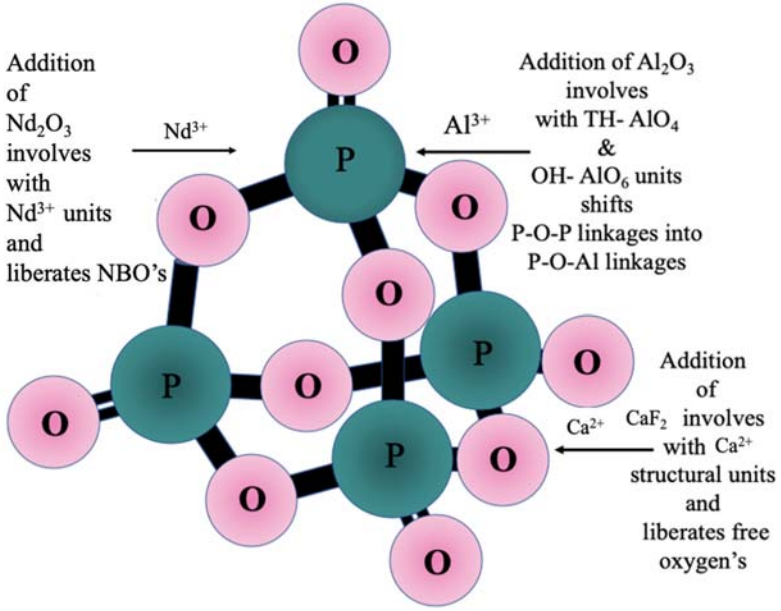

Figure 17.6 Molecular structure of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses. Mac-based Chem Draw Ultra version 12.0 was used to plot the figure.

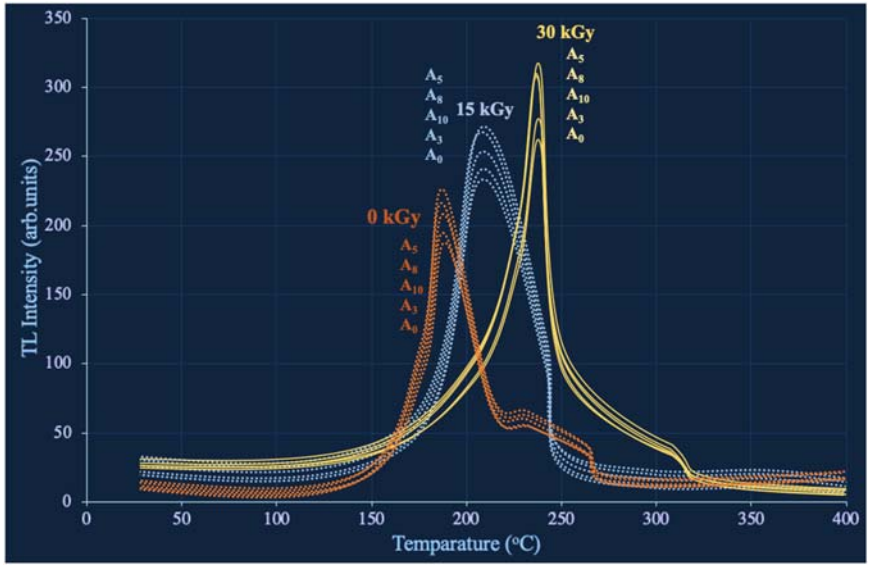

Figure 17.7 Thermoluminescence of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses recorded at various irradiation dose (0, 15, 30 kGy) range from room temperature to 400°C. The temperatures are taken up to an accuracy of ±0.1 C.

$$C_\tau = 1.510 + 3(\mu - 0.42);\ C_\delta = 0.976 + 7.3\ (\mu - 0.42);$$
$$C_\omega = 2.52 + 10.2(\mu - 0.42);$$
$$b_\tau = 1.510 + 3(\mu - 0.42);\ b_\delta = 0;\ b_\omega = 0;\ \mu = \frac{\delta}{\omega};$$

T_m—peak temperature maximum

μ_{sf}— shape symmetry factor

Table 17.1 presents the complete information regarding the TL measurements under 0, 15, and 30 kGy γ-irradiation doses. The results drawn from the TL measurements recommend that the induced electron and trap centers intensities both contribute to the unconventional referencing of TL output. Trap depth parameters such as A.E. (E_τ, E_δ, and E_ω) form symmetry ratios that are demonstrated to be ideal for the glass code with a concentration of 5 mol% Al_2O_3. The term "thermoluminescence" (TL) refers to the phenomena of light being produced by external heat energy. By adding the necessary irradiation, further traps were added. Analysis of TL investigations of existing materials was done under constant irradiation. Variations in the Ca^{2+} and Al^{3+} ion concentrations increase structural flaws such as interstitial areas or trap centers. Existing phosphate glasses include CaF_2, which along with all positive metal ions including Ca^{2+}, Al^{3+}, and Nd^{3+} ions, result in enhanced TL output when exposed to γ-irradiation. Under the proper γ-irradiation, Ca^{2+} ions of CaF_2 are oxidized into Ca^{3+} ions during this process. Additionally, this resulted in the release of electron mass, which can act as a trap and trigger enhanced thermoluminescence. Similarly, Nd^{3+} ions of Nd_2O_3 are oxidized to Nd^{4+} ions, which further results in trap centers that may be just below the conduction band of Nd^{3+}. The depth of the trap centers inside the existing materials was found to be ideal for the sample code "A5," which might work well with this TL mechanism. A higher number of produced Al-O-P connections along with an increase in the ratio of Al_2O_3 to CaF_2 might result in enhanced natural TL emission. The output intensities of the currently observed thermoluminescence may have increased the amount of Ca-O and Al-O bond connections and may be influenced by the site symmetry of both Ca^{2+} and Al^{3+} ions (Veerabhadra Rao et al., 2022). In this approach, the Ca atom with a larger surface area was oxidized first, followed by Nd, Ca, and Al atoms. In general, additional trap centers may be produced by atoms whose surface areas are totally exposed to the incoming radiation (Guntu, 2020). Asymmetry in glass is caused by the interionic interactions between the

Ca^{2+} and Nd^{3+} ions as well as the Al^{3+} ions, which affect minor orders of volume defects throughout the whole glass. The sample with a 5 mol% Al_2O_3 concentration exhibits the highest order of thermoluminescence and has the most surface area that can be exposed to Pb^{2+} and Nd^{3+} ions. According to all the observed TL experiments under the required gamma irradiation, the sample $\gamma\mathbf{A_5}$—is carried out most effectively for enhanced trap depth assessments and may be a helpful TL resource.

17.3.3 Optical studies

The variation in absorption strength as a function of frequency that happens when photonic energy is absorbed by the sample from the source is known as the absorption spectrum. With increasing Al_2O_3 content up to 5 mol%, the optical band edge (344.1 nm) of previous glass tests was shown to be growing. After that, the trend for OBE values is quite the opposite. Fig. 17.8 represents UV optical absorption spectra of existing glasses mixed with different concentrations of Al_2O_3 to reveal absorption bands such as $^4I_{9/2}$ (ground state) to the various excited states $^2G_{9/2} + {}^2D_{3/2} + {}^2K_{15/2}$, $^2G_{1/2} + {}^2G_{7/2}$, $^2H_{11/2}$,$^4G_{9/2}$, $^4G_{7/2}$, $^2P_{1/2} + {}^2D_{5/2}$, $^4F_{9/2}$, $^2F_{1/2} + {}^2H_{9/2}$ & $^4F_{3/2}$ (Rama Krishna Chand et al., 2022). All peak intensities were observed to be highest for the glass code $\mathbf{A_5}$. The deviation observed suggests that the most practical fit between theory and research represents

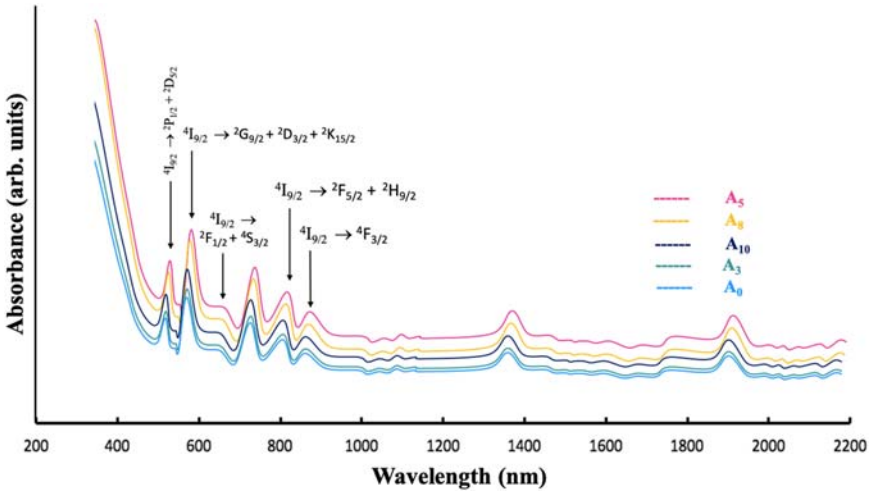

Figure 17.8 Optical absorption spectra of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses recorded at room temperature within the wavelength range of 200–2200 nm. The wavelengths are taken up to an accuracy of ±0.1 nm.

the applicability of J-O theory. JO parameter (Ω_λ) evaluation of existing glasses was found to be an increase $\Omega_2 > \Omega_4 > \Omega_6$ in the order. The following equivalence (Anil Kumar et al., 2021) was used to obtain f_{exp} (experimental oscillator strength), f_{cal} (calculated oscillator strength), and J-O intensity parameters of absorption transitions:

$$f_{exp} = 4.319 \times 10^{-9} \int \varepsilon(\nu) d\nu$$

$$f_{cal} = \frac{8\pi^2 mc\upsilon}{3h(2J+1)} \frac{(n^2+2)^2}{9n} \sum_{\lambda=2,4,6} \Omega_\lambda \langle \varphi J \| U^\lambda \| \varphi' J' \rangle^2$$

$$\delta_{rms} = \left[\frac{\sum \left(f_{exp} - f_{cal} \right)^2}{N-3} \right]^{\frac{1}{2}}$$

where, δ_{rms} is the root mean square deviation; ε (υ) is the molar absorptivity at frequency ν (in cm^{-1}); m is the mass of the electron; c is the velocity of light in a vacuum; ν is the wave number in cm^{-1}; h is Planck's constant; n is the refractive index; Ω_λ is the JO parameters; and $||U^\lambda||^2$ is the squared doubly reduced matrix elements of the unit tensor operator of the rank $\lambda = 2$, 4, and 6.

The overall number of transitions used in the fitting process is N. In most cases, a photon with energy "hv" interacts with electrons in the valence band and causes them to rise to the conduction band, spanning the band gap between the conduction and valance bands. Using the Mott and Davis hypothesis, one may calculate this band gap in materials. The absorption coefficient $\alpha(\nu)$ in terms of photon energy (h), as per the Mott and Davis theory, is given by

$$\alpha(\nu) = \frac{B(\mathrm{hv} - E_g)^n}{\mathrm{hv}}$$

where n is the index number depending on the kind of electronic transition, $n = 2$ and 1/2 corresponding to indirect and direct permitted transitions, respectively; B is the band tailing parameter; E_g is the optical band gap energy; and hv is the incident photon energy. The concentration of Nd_2O_3 dopant in the current study activity is set at 1 mol%. The Al_2O_3 concentration rises by 0, 3, 5, 8, and 10 mol%.

In the complete opposite direction, CaF_2 concentration dropped from 29 to 19 mol%. The optical absorption spectra of an $Al_xCa_{y-x}P_{70}$ glass host doped with 1 mol percent Nd_2O_3 were affected by different CaF_2 and

Al_2O_3 concentrations. Due of an imbalance in the interatomic interactions between the Ca^{2+} and Al^{3+} ions, the lattice of the current Nd_2O_3-doped phosphate glass host results in bonding defects. Additionally, this may cause tiny orders of gaps or fractures that, when they are opened, allow both Nd^{3+} and Ca^{2+} ions to be significantly influenced by gamma radiation, which would then improve the order of the trap centers. Similarly, more Nd^{3+} ions could be able to penetrate the second level of optical absorption if there was a greater surface area created by crystal defects in the phosphate glass lattice (Rama Krishna Chand et al., 2021). The incorporation of Nd_2O_3 into existing $Al_xCa_{y-x}P_{70}$ materials has an impact on the small size of trap centers and their dimensions, which were brought about by variations in Al_2O_3 and CaF_2 concentrations in the glass materials. Bonding defects and extra trapped centers created by gamma radiation improve all optical evolutions, suggesting the possibility of a second level of optical energy transformation. This happened on its own because photon energy from the provided optical energy filled the trap centers. The concentration of Nd_2O_3 dopant in the current study effort is set at 0.1 mol%. There is an increase in Al_2O_3 content from 0 to 10 mol%. Due of an imbalance in the interatomic interactions between the Ca^{2+} and Al^{3+} ions, the lattice of the current Nd_2O_3-doped $Al_xCa_{y-x}P_{70}$ glass host results in bonding defects. Additionally, this might result in tiny orders of gaps or fractures that, when opened, allow both Nd^{3+} and Ca^{2+} ions to be significantly influenced by gamma radiation, which would improve the order of trap centers. In a similar vein, more Nd^{3+} ions may be able to absorb light at the second level due to the phosphate lattice's increased surface area caused by crystal defects. And this is fairly high considering that the sample code has an Al_2O_3 content of 5 mol% (Guntu, 2019). These current glasses' luminescence spectra, which were captured at room temperature and stimulated at 350 and 850 nm, are shown in Fig. 17.9. The well-defined band $^4F_{3/2} \rightarrow {}^4I_{11/2}$ (1061 nm) was visible in the PL spectra. Peak intensities have been determined to be optimal for glass code A_5 out of all the available glass codes (Polymeris et al., 2017). It is suggested by the radiative evolutions, such as effective bandwidths of $\Delta\lambda \sim 39$ nm, stimulated emission cross-sections of $\sigma \sim 3.65 \times 10^{-20}\text{cm}^2$, transition probabilities of $A_t \sim 1635\ \text{s}^{-1}$, radiative lifetimes of $\tau_{rad} \sim 281\ \mu\text{s}$), and branching ratios of $\beta \sim 56\%$, that the sample code $\mathbf{A_5}$ is the useful 1.06 m emissive material (Swamy et al., 2014; Ivascu et al., 2011). The information on the luminous spectra of current glass testing is summarized in Table 17.1.

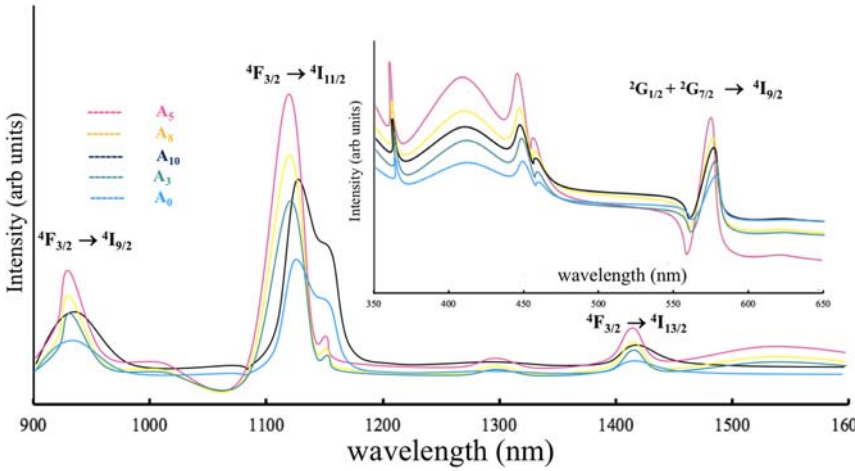

Figure 17.9 Photoluminescence spectra of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses recorded at room temperature within the wavelength range of 350–1600 nm and with excitation wavelengths of 300 and 850 nm. The wavelengths are taken up to an accuracy of ±0.1 nm.

17.3.4 Biocompatible studies

Figs. 17.10 and 17.11 address the X-ray diffraction, surface morphology, and chemical analyses of immersed existing glasses in simulated body fluid (SBF) for around 720 h (30 days) recorded at room temperature. The present study is about the results reported of vitro bioactive investigations, corresponding to the Al^{3+} ionic influence on $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses. The structural observations from Figs. 17.10 and 17.11 and degradation nature in SBF advised of a very thin layer of crystalline hydroxyapatite grains on the surfaces of existing materials. Hydroxyapatite $Ca_5(PO_4)_3$ crystal grains were observed at 25.3 degrees (0 0 2), 33.1 degree (2 1 1), 49.8 degrees (2 1 3), and 54.6 degrees (0 0 4); average dimensions of the crystallites were evaluated to be ~117 nm (JCPDS no. 09-0432). Degraded content evolutions of existing glasses in simulated fluid are estimated by weight loss and pH (Figs. 17.12 and 17.13) of the simulated fluid remaining (Anil Kumar et al., 2021). The weight loss and pH data, together with the hydroxyapatite deposition on the surface of the samples that was found to be more prevalent in sample code "A_5," indicate that the degrading nature is a function of the Al_2O_3 concentration rising up to 5 mol%. Additionally, the in vitro bioactive investigations of Al_2O_3 mixed current materials has shown the deposition of crystalline hydroxyapatite grains under the effect of Al^{3+} ions

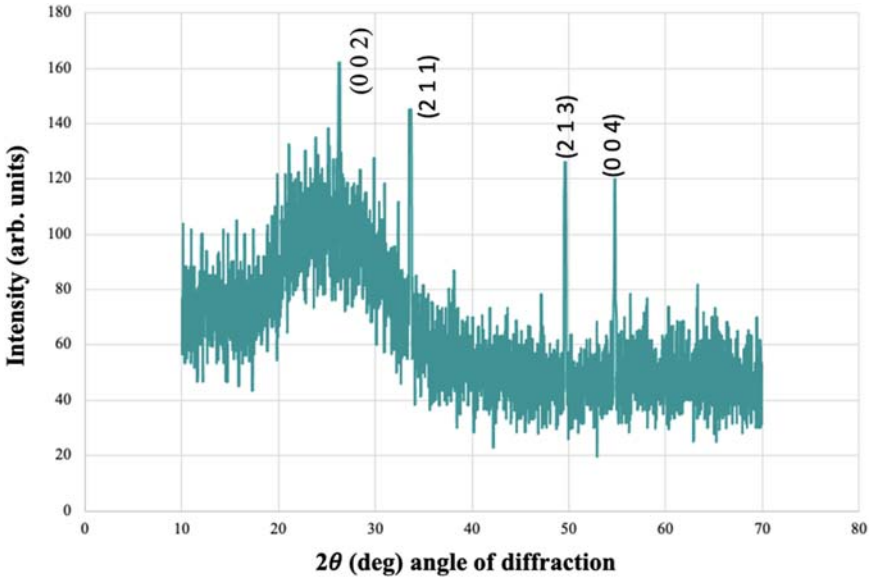

Figure 17.10 X-ray diffraction pattern of immersed sample code: A_5 in SBF of$Al_xCa_{y-x}Nd_{01}P_{70}$ glasses (JCPDS no. 09-0432). The diffraction angles are taken up to an accuracy of ±0.1°.

on the surfaces of the existing materials, which may be beneficial for a variety of advanced biomedical applications (Marghoub et al., 2019).

On the surface of glass materials, P_2O_5 often forms a layer of hydroxyapatite. The use of CaF_2 has the added benefit of speeding up the formation of the hydroxyapatite layer (Vijaya Kumari et al., 2019; Canillas et al., 2017). Together with P_2O_5, CaF_2 and CaO modify the structure of the glass network to create (calcium hydroxyapatite) $Ca_5(PO_4)_3(OH,F)$. The phosphate units' bonds are broken by oxygen from CaO, while Ca^{2+} ions are involved in SBF and create $Ca(OH)_2$. H_3PO_4 (phosphoric acid) deionizes H_2O in a simulated fluid by incorporating (Bai et al., 2017) P_2O_5.

$$5\ Ca\ (OH)_2 + 3\ H_3PO_4 \rightarrow Ca_5(PO_4)_3OH + 9\ H_2O$$

After soaking, neodymium ions, or Nd^{3+}, are quickly diffused from the glass and form apatite nucleation centers. Additionally, this accelerates the rate at which adjacent calcium and phosphate ions and trigonal neodymium ions interact. The supply of Ca^{2+} ions from the submerged glasses speeds up the development of apatite in the fluid. Al^{3+} ions interact with octahedral (AlO_6) and tetrahedral (AlO_4) units. It is anticipated that the tetrahedral

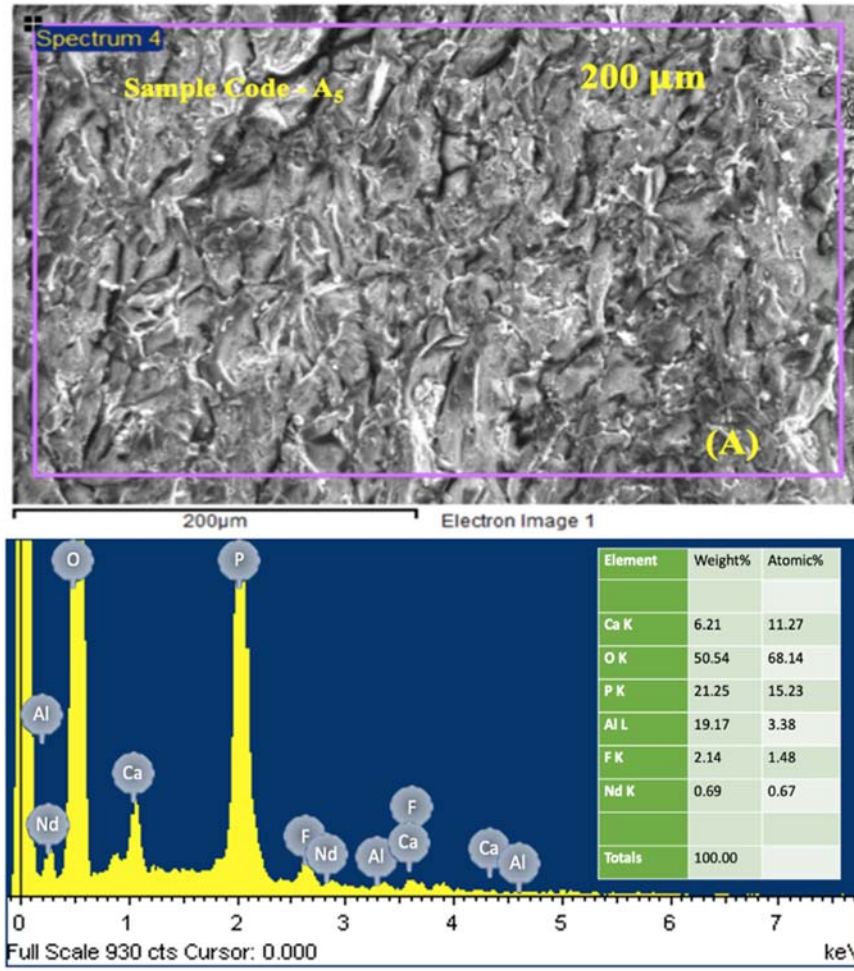

Figure 17.11 Chemical analysis of immersed sample code: A_5 in SBF of$Al_xCa_{y-x}Nd_{01}P_{70}$ glasses. Inset illustrates the surface morphology of sample A_5 recorded with 200 µm resolution.

AlO_4 ions will form a layer of Nd/Al by combining with Nd_2O_3 units (Liao et al., 2020; Perumal et al., 2019). Neodymium has a higher electronegativity than aluminum, therefore the Nd/Al layer can be considered to be in the form of Al^{3+}/Nd^{3+} to preserve the charge balance. Higher concentrations of OH- Al^{3+}ions would promote diffused Nd^{3+} ions, changing the tetrahedrally positioned locations of the aluminum ions (Asyikin et al., 2020; Gupta and Santhiya, 2017; Al-Bakhsh et al., 2019).

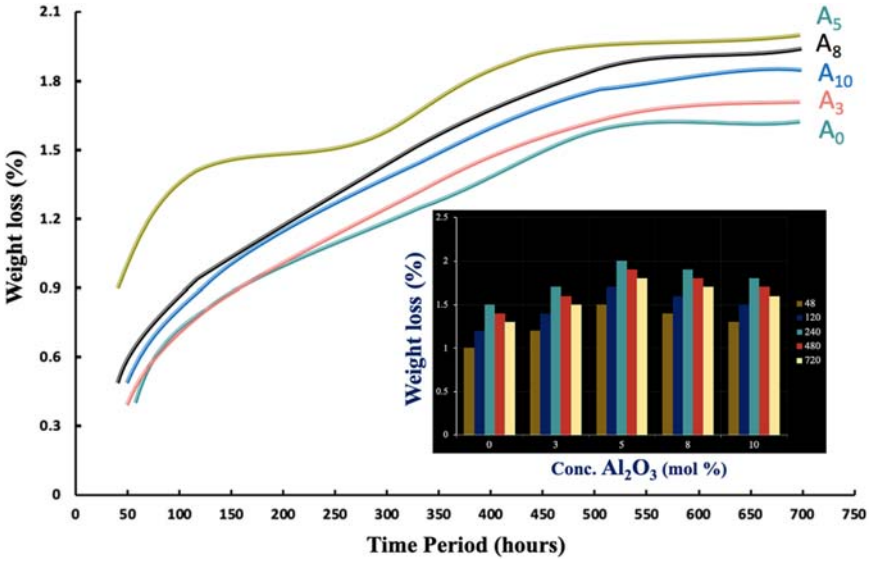

Figure 17.12 Variations in weight loss of immersed existing glasses in simulated body fluid with time in hours. Inset represents variations of weight loss of immersed samples in SBF with Al_2O_3 concentration at various intervals of time in hours.

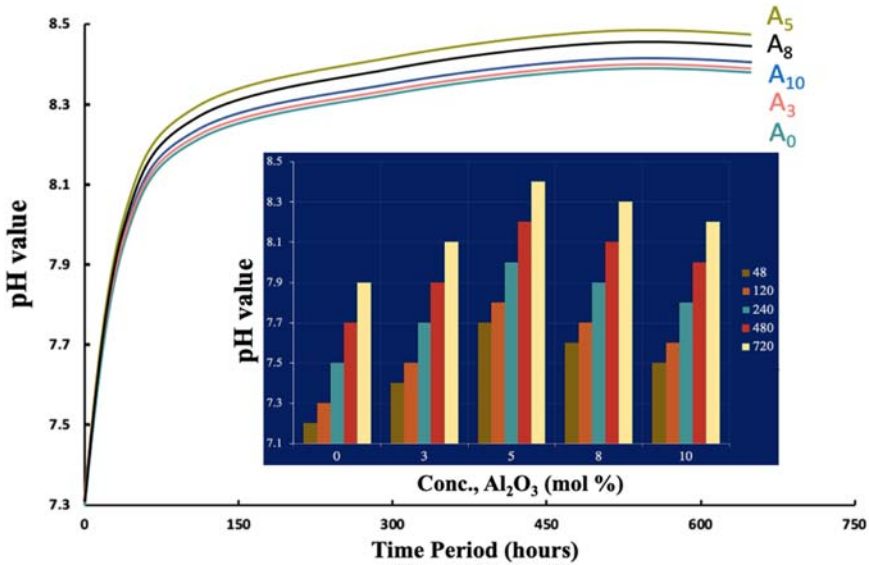

Figure 17.13 pH of SBF solution calculated at various time intervals of existing glasses. Inset represents the pH of residual solution calculated for each sample after immersion with Al_2O_3 concentration at various intervals of time in hours.

This causes a sample code "A5" to develop with the greatest concentration of hydroxyapatite. The changes in weight loss and pH of the leftover simulated fluid with Al_2O_3 concentration are strongly in favor of this hypothesis.

17.4 Summary and conclusion

We have selected $Al_xCa_{y-x}Nd_{01}P_{70}$ chemical make-up for standing analysis in order to prepare glass series. Bioactivity degradation and luminescent techniques are used to characterize existing samples.

- TL studies under different γ-irradiation dose ranges of $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses are reported. The sample code "A_5" exhibiting good low AE ($E_{\tau} \sim 0.997$, $E_{\delta} \sim 0.503$, and $E_{\omega} \sim 0.846$ eV) and shape symmetry factor (~ 0.489) is advised to be a useful TL asset.
- JO parameters (~ 9.31, 4.71, and 4.31×10^{-20}cm^2), bandwidth (~ 39 nm), stimulated emission cross-section (3.65×10^{-20}cm^2), radiative lifetime (~ 281 μs), and branching ratio ($\sim 56\%$) assessed by optical studies indicated that the $Al_xCa_{y-x}Nd_{01}P_{70}$ glasses are a useful optical resource.
- The in vitro bioactivity behaviors of existing materials are reported, and the disintegration rate in SBF materials is calculated. The structural results of post-immersed glasses, such as pH and weight loss plots, indicated the growth of carbonated crystal grains of the hydroxyapatite layer and the highest degradability for the sample code $\mathbf{A_5}$. Conclusively, the bioactive degradation studies reveal that the thin layer of embedded crystalline hydroxyapatite deposition on the surface of existing glassy materials might be a useful biomedical resource.

According to all structural, biological activity, and optical evaluations of the available glass resources, sample code "A_5" is the most beneficial material for both luminous and biological medical applications.

CHAPTER 18

A prospective utilization of biodegradable polymers for controlled drug-delivery applications

Dinesh Puri[1], Deepak Choudhary[2], Mohd Yasir[3], Rosaline Mishra[4], Sanjay Sharma[5], Radha Goel[6] and Praveen Kumar Gaur[4]

18.1 Introduction

The approval of the first biodegradable suture in the 1960s opened a new vista of use of polymers in the medical world. Polymers play a very important role in the release of hydrophilic and hydrophobic drug substances.

Depending on the origin of biodegradable polymers, they can be divided into two categories: natural and synthetic polymers. There are several advantages to synthetic polymers over natural polymers in terms of mechanical and degradation properties. However, due to excellent biocompatibility and biodegradation, natural polymers remain the first choice of researchers (Piskin, 1995; Middleton and Tipton, 2000).

Biodegradation is a process in which polymers are decomposed by the action of enzymes and/or chemicals, through a living organism such as bacteria or fungi. Sometimes environmental factors including abiotic reactions such as oxidation, hydrolysis, and photodegradation, can also alter the polymer nature, which could affect the biocompatibiliy and biodegradation (Albertsson and Karlsson, 1996). Drug targeting without affect other sites in the body remains a challenge for researchers and these polymers play an important role in delivering drugs to a particular site in a

controlled manner (Kwon and Furgeson, 2007). Over a long period of time, biodegradable polymeric materials have been the choice of researchers for drug delivery due to their remarkable properties such as biocompatibility and biodegradability, with minimal toxicity or side effects (Heller, 1980). These polymers can be used in controlled drug delivery, implants, sutures, macroscopic drug depots, injectable micro- and nano-scale drug delivery. Over the last few years, biodegradable polymers with high molecular weight such as heparin, hyaluronic acid, dextran, pullulan, etc. have been utilized for designing controlled drug-delivery systems, especially for incorporating protein- or nucleic acid-based drugs, but these polymers display slow degradation in an in vivo system and hence may accumulate in the tissue site. To overcome this issue, low-molecular-weight biodegradable polymers have gained increased attention in controlled-release formulation development due to their greater permeability, solubility, and association efficiency because of their smaller particle size.

These polymers are utilized to design various polymeric nano drug-delivery systems, such as microspheres or microcapsules. In microspheres, the drug is encapsulated in a polymeric shell, while in nanocapsules, the drug is dispersed in a polymeric matrix (Idrees et al., 2020). Both types of nanomedicine carriers are presented in Fig. 18.1. Depending upon the target organ, a suitable biodegradable polymer can be selected as a drug-delivery carrier to deliver the drug to a specific site/organ in a controlled manner. Biodegradable polymers can be used in both topical and systemic delivery of drug release. Although these polymers are the choice of researchers, there may be a challenge for researchers to use biodegradable polymers in drug delivery due to compatibility issues of the polymer with

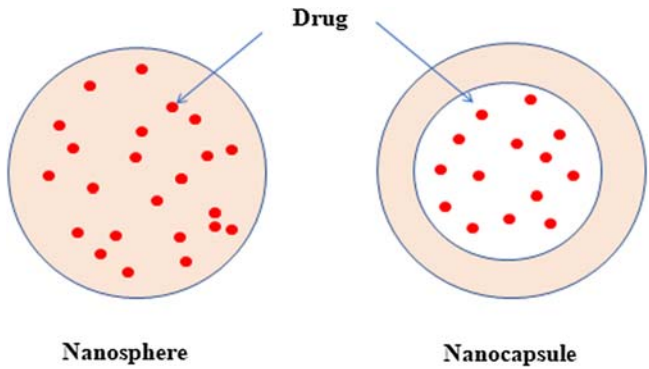

Figure 18.1 Types of nanomedicine.

body tissue (Kwon and Furgeson, 2007; Heller, 1980). Controlled drug-delivery systems are the area where biodegradable polymers are applied to control the release pattern of drugs (Brannon-Peppas, 1995; Gültekin and Değim, 2013). The FDA has also approved a number of polymers for use in controlled drug delivery and these mostly have amide, ester, and anhydride linkages that could be easily degraded (Osorno et al., 2021; Prajapati et al., 2019). Factors such as the mechanical properties, rate of degradation, biocompatibility, stability. and cost of polymers are among the criteria for the selection of polymers (Gunatillake et al., 2006).

18.2 Classification of biodegradable polymers for CDDS

There are many distinct types of biodegradable polymers used for drug delivery. Polymers can be divided into two groups according to their origin: natural and synthetic (Asghari et al., 2017; Deb et al., 2018; Dmour and Taha, 2018). A detailed classification of biodegradable polymers is provided in Fig. 18.2. Both natural and synthetic biodegradable polymers have various advantages such as biodegradability, compatibility, low toxicity, control, or/and sustained-release properties including specific targeted drug-delivery approaches (Doppalapudi et al., 2016). Some of the chemical structures of polymers are provided in Fig. 18.3.

Synthetic polymers are superior to natural polymers due to the contamination of microbes, batch-wise variation, and hydration of natural polymers in an uncontrolled manner (Gavasane, 2014). The side effects of drugs may be reduced by using biodegradable polymers in the formulation of nanomedicines. Biocompatible and harmless by-products are produced during the degradation of these polymers (Idrees et al., 2020).

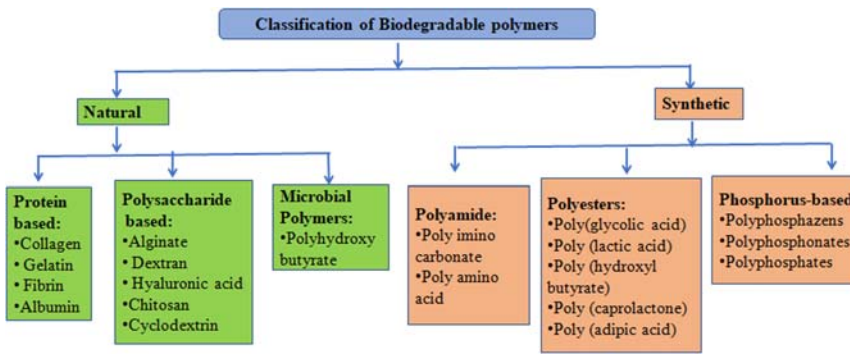

Figure 18.2 Classification of biodegradable polymers.

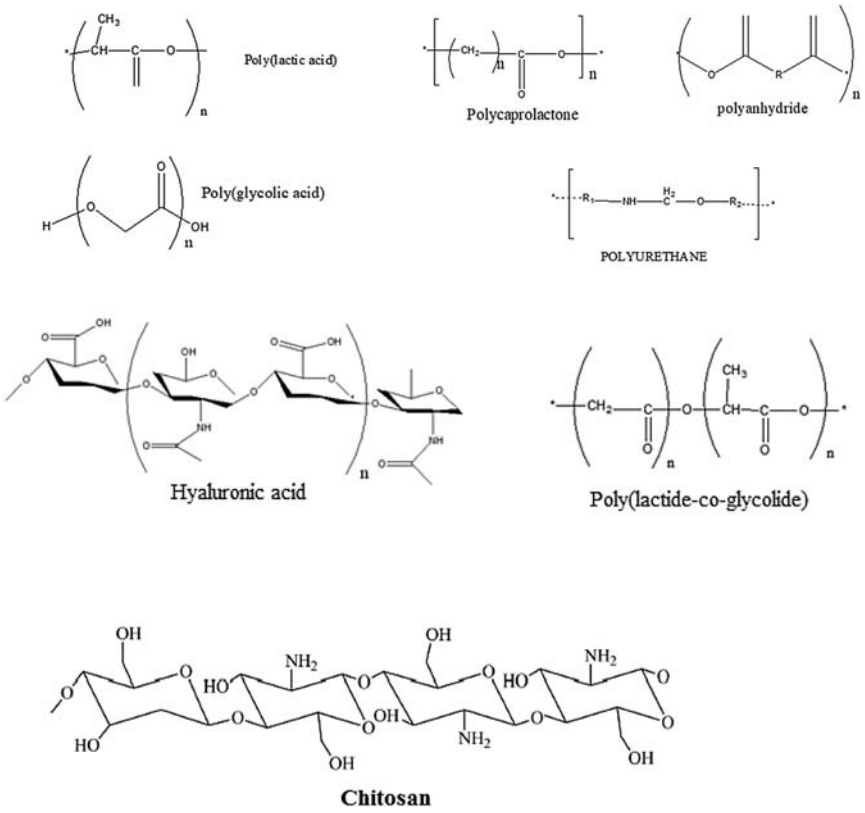

Figure 18.3 Examples of biodegradable polymers with chemical structures.

18.2.1 Collagen

Collagen has been widely applied in drug-delivery systems as well as in tissue engineering due to its excellent biocompatibility, moldability, mechanical properties, and easy modification with low antigenicity (Kwon and Furgeson, 2007; Lee et al., 2001; Wallace and Rosenblatt, 2003). It is practically insoluble in water, although its solubility can be increased by lowering the solutions' pH (Dmour and Taha, 2018). Rathore et al. fabricated collagen-based nanoparticles to increase the therapeutic effect of silymarin against cerebral neuronal injury. The results showed the remarkable effects on a group treated with nano-silymarin compared to a group treated with

silymarin (Rathore et al., 2020). Wallace et al. formulated collagen gel for the sustained release of therapeutic agents (Wallace and Rosenblatt, 2003). Nicklas et al. prepared hydrogel of collagen-loaded nanoparticles for prolonged release (up to 24 h) of estradiol (Nicklas et al., 2009). Nagarajan et al. fabricated solid collagen nanoparticles of theophylline through an electrospray deposition method. Cross-linking of collagen molecules helps in the controlled release of theophylline (Nagarajan et al., 2014).

18.2.2 Gelatin

Gelatin is a widely used polymer obtained by partial acid—base hydrolysis of animal collagen (Kumari et al., 2010). Due to its versatile features, it can be used to design various carrier systems such as microparticles, nanoparticles, fibers, and hydrogel (Foox and Zilberman, 2015). Its biodegradable, bioactive, and nontoxic properties makes it suitable for use in controlled release (Elzoghby, 2013). Mannan-coated gelatin nanoparticles showed sustained-release results of didanosine for up to 24 h, and, due to its sustained action, the frequency of administration was reduced which could lead to increased patient compliance (Kaur et al., 2008). The release of sulfamethoxazole was controlled by gelatin nanoparticles (100—300 nm) for up to 10 h (Bajpai and Choubey, 2005). Insulin release was controlled by the synthesis of gelatin-based nanoparticles (Goswami et al., 2009).

18.2.3 Chitosan

Chitosan is a biopolymer which shows potential application in drug-delivery systems (Kamaly et al., 2016). Chitin is changed to the natural polymer chitosan by an alkaline deacetylation process. Its non-toxic, biocompatible, and biodegradable properties make it a viable polymer for both established and cutting-edge drug delivery, gene delivery, and other medical applications (Foox and Zilberman, 2015; Elzoghby, 2013). It is used extensively in wound healing (Kim et al., 2007), oral drug delivery (Fonte et al., 2015), gene delivery (Molinaro et al., 2013), and pulmonary drug delivery (Benediktsdóttir et al., 2014). Membranes used in hemodialysis are a significant biomedical material of the 21st century due to their numerous uses, such as in artificial skin or bioactive wound dressings (Kaur et al., 2008). Chitosan that has undergone chemical modification can be

used to regulate the drug-release profile of bioactive compounds (Prabaharan, 2008). Lactic acid grafted chitosan nanoparticles showed high encapsulation efficiency with prolonged release of protein for up to 4 weeks (Bhattarai et al., 2006). Polyelectrolyte complex gel beads containing Ibuprofen were prepared by phosphorylated chitosan for controlled release through oral administration (Phyu Phyu et al., 2003). Phosphorous-containing chitosan-based beads were developed for the controlled release of indometacin (Jayakumar et al., 2006). Different chitosan polyelectrolyte complex-based microparticles of antibacterials for persistent and effective lung infection have been developed. A controlled drug device was developed using the graft copolymerization technique (Mishra et al., 2017). Drug release of up to 24 h was achieved by chitosan nanoparticles of cyclosporin A (De Campos et al., 2001). Chitosan-based nanoparticles of amiodarone completely released the drug in 14 days (Buyuk1 et al., 2020). Extended release of metronidazole was obtained through bionanocomposite beads of chitosan/graphene oxide (Kumar et al., 2021). Controlled release of Ketorolac tromethamine was obtained by cellulose nanofibrils/chitosan-based transdermal drug delivery (Sarkar et al., 2017). In vitro release of itraconazole was seen for 24 h using chitosan nanoparticles (Jafarinejad et al., 2012). Estradiol chitosan nanoparticles (Wang et al., 2008) and bioavailability and brain targeting of rivastigmine could be improved through the synthesis of nanoparticles using chitosan (Fazil et al., 2012). The hydrogel of a controlled drug-release system dependent on pH-sensitive chitosan and polyvinyl pyrrolidone for the administration of amoxicillin was created (De Campos et al., 2001). To regulate the release, chitosan and gum arabic were used to create insulin nanoparticles using the ionic gelation method (Buyuk1 et al., 2020). Chitosan-based mucoadhesive liposomes were created for localized sustained release of two model medicines of fluorescein isothiocyanate dextran with molecular weights of 4000 and 20,000 Da (Kumar et al., 2021).

18.2.4 Alginate

The polysaccharide known as alginate, which is derived from brown seaweeds, is made up of a series of two (1—4)-linked monomers called L-guluronate (G) and D-mannuronate (M) (Sarkar et al., 2017). Alginic acid is hydrated at low pH, resulting in the production of a high-viscosity acid gel that can be crucial in the creation of a formulation with controlled release

(Jafarinejad et al., 2012). The release of insulin for oral delivery was considerably delayed by a nanoemulsion coated with alginate/chitosan (Wang et al., 2008). Sustained drug delivery of indometacin was obtained through alginate-encapsulated mesoporous silica nanospheres (Hu et al., 2014). The release of vancomycin was controlled (22 μg per day for 14 days) by preparing lyophilized microparticles of chitosan−alginate polymers (Unagolla and Jayasuriya, 2018). An orally controlled release system of the macromolecular drug Blue Dextran was developed in the form of alginate gel beads (Kim and Lee, 1992). Hydrocortisone hemisuccinate-containing alginate microparticles were prepared for colonic drug delivery (Samak et al., 2017). Zn^{2+}-cross-linked alginate was used to prepare microparticles for delivery of bovine serum albumin through a spray-drying process (Karimi et al., 2016).

18.2.5 Albumin

Albumin protein plays a vital role as a biodegradable nanodrug carrier in the pharmaceutical field. Its versatile properties of targeted delivery capacity with nontoxicity and nonimmunogenicity make it attractive for researchers in treatments against tumor cells (Elzoghby, 2013; Karimi et al., 2016). A variety of albumins are used in various biomedical applications, including ovalbumin which is obtained from egg white, bovine serum albumin, human serum albumin, and rat serum album (Peters, 1985). Curcumin- (Kim et al., 2011) and doxorubicin-loaded (Dreis et al., 2007) human serum albumin nanoparticles were prepared which showed a greater therapeutic effect against cancer cells.

18.2.6 Polyhydroxybutyrate

Polyhydroxybutyrate is a bioderived polyester intracellular polymer which is synthesized for the source of carbon and energy in bacteria (Li et al., 2007; Suriyamongkol et al., 2007). Microspheres of rifampicin (Kassab et al., 1997), microspheres and microcapsules containing tetracycline (Gursel, 1999), and Tramadol-encapsulated microspheres showed drug release for more than 6 days (Salman et al., 2003), and curcumin nanoparticles (Aguilar-Rabiela et al., 2020) were prepared using polyhydroxybutyrate.

18.2.7 Polyamides

Polymers made up of repeating units that are linked by amide bonds are called polyamides. These may be natural like proteins or synthetic like

nylon (Boddu et al., 2021). Gachard et al. prepared a benzocaine controlled-release matrix using covalently linked N-protected poly(L-crystal-L-cystine) and poly(adipoyl-L-lysine) (Gachard et al., 1997). Nanoparticles for the controlled release of celecoxib were prepared using new s-triazine polyamides which contain glycine and thioglycolic acid (Khattab et al., 2016).

18.2.8 Polyesters

Due to the presence of a hydrolysable ester linkage in the backbone of the polyester family it is mostly used in controlled-release formulations. Poly-glycolic-acid, poly-lactic-acid, poly-hydroxyl-butyrate, poly-caprolactone, and poly-adipic acid are examples of polyesters which are used in formulations (Bhise et al., 2007; Jerbić, 2018; Christensen et al., 2007). Sustained-release microspheres of Nimesulide were prepared by polylactic acid (Freitas and Marchetti, 2005). Nanoparticles prepared by polylactic acid can retain the drug for at least 24 h in dermatotherapy (Rancan et al., 2009). Poly(lactic-co-glycolic acid) can also be used for controlled drug release (Hines and Kaplan, 2013), it is an FDA- and EMA-approved polymer for parenteral administration and is used for many hydrophilic and hydrophobic drugs (Danhier et al., 2012). Curcumin-loaded nanoparticles for prostate gland treatment were prepared by PLGA (Yallapu et al., 2012). Poly(caprolactone) can be used for the preparation of microspheres and nanospheres (Sinha et al., 2004) such as insulin-loaded particles for controlled drug release (Mukerjee et al., 2007), hollow nanoparticles (Park et al., 2019a), Holmium-165-loaded microspheres (Geraldes et al., 2011), theophylline nanoparticles (Jelvehgari et al. 2010), and repaglinide microspheres (Jagdish et al., 2009). Poly(glycerol adipate) was used for the preparation of nanoparticles of nonsteroidal antiinflammatory drugs (Wahab et al., 2012).

18.2.9 Phosphorus-based polymers

Phosphazenes and phosphoester are two major classes that contain phosphorus and are used for nanoformulations. Polyphosphazenes are a new class of biodegradable polymer because they can control deterioration and structural flexibility (Lakshmi et al., 2003; Ni et al., 2020; Ullah et al., 2017) and they have been tested and used as a controlled-release agent for several drugs (Schacht et al., 1996). Like the controlled release of polyphosphazene

microspheres of insulin (Caliceti et al., 2000), there are sustained-release polymeric nanocarriers of indometacin (Zhang et al., 2006) and indometacin micelle (Ni et al., 2020) for arthritis.

18.3 Application of biodegradable polymers in drug delivery

18.3.1 Mucoadhesive drug release

To increase the therapeutic action and medication plasma concentration, mucoadhesive dosage forms are employed to deliver a regulated rate of release through longer retention at the site of application (Ni et al., 2020; Ullah et al., 2017). Chitosan has been widely utilized as a mucoadhesive polymer because of its good biodegradability and biocompatibility (Schacht et al., 1996). For the treatment of bladder cancer, Moustafa et al. produced mucoadhesive nanodiamonds coated with chitosan (Caliceti et al., 2000). Modified boronated chitosan was created by Kolawole et al. and employed as a mucoadhesive polymer for intravesical medication delivery (Zhang et al., 2006). Dexamethasone–glycol chitosan (Dex-GCS) nanoparticles with mucoadhesive properties were created by Yu et al. for prolonged precorneal duration ocular medication administration (Alagha et al., 2020). Alagha et al. developed porous mucoadhesive biosponges of dexamethasone for oral mucositis by using collage, chitosan, and a blend of both. In vitro drug release has shown that a formulation based on a collagen–chitosan (1:1) blend can control release for up to 10 h (Alagha et al., 2020).

18.3.2 Controlled drug-delivery release

This type of system delivers the drug at a predetermined rate for a specific time and solves the problem related to conventional drug-delivery systems (Adepu and Ramakrishna, 2021). Buyuk et al. synthesized amiodarone-loaded chitosan nanoparticles which completely released the drug by the end of 14 days (Buyuk et al., 2020). Sorasitthiyanukarn et al. prepared chitosan/alginate nanoparticles for oral delivery of curcumin diglutaric acid (CG) for carcinogenic therapy. In their study, they found that CG-loaded chitosan/alginate nanoparticles showed sustained release after 24 h for all conditions (Sorasitthiyanukarn et al., 2018). Maghsoudi et al. prepared nanoparticles of curcumin using different polysaccharides including chitosan, alginate, and starch for anticarcinogenic activity.

Curcumin was released for 96 h from nanoparticles during an in vitro study (Maghsoudi et al., 2017). Agnohotri and Aminabhavi achieved controlled release of clozapine for up to 12 h through fabrication of nanoparticles based on chitosan (Agnihotri and Aminabhavi, 2004). Yang et al. formulated controlled-release steroidal saponins (SS)-loaded microspheres which showed retarded release of SS during an in vitro release study (Yang et al., 2019). Terzopoulou et al. prepared collagen-based curcumin patches for psoriasis topical therapy. Within the first burst, the release of curcumin continued and after 24 h, it had reached 55% (Terzopoulou et al., 2020). Poly 3-hydroxybutyrate biopolymer was used to produce films by Villegas et al., who achieved controlled release for the appropriate duration (about 14 days) (Fu and Kao, 2010). For the treatment of prostate cancer, Guo et al. created PLGA nanoparticles that were loaded with bicalutamide. The outcome demonstrated that the medication was released gradually, with 60% of the drug released by the end of 96 h at pH 7.4 (Alexis et al., 2004). Vancomycin was delivered under controlled conditions using poly(caprolactone) by Rai et al. to treat MSRA infection (Amkraut et al., 1989). Naproxen subcutaneous implants based on polyphosphazene were created by Conforti et al. for regulated release over a 28-day period (Conforti et al., 1996).

18.4 Mechanism involved in controlled release through polymers

Drug molecules are normally transported from the polymer matrix to the exterior before they eventually enter the surrounding environment (Uhrich et al., 1999).

To produce a steady-state drug concentration in the therapeutic range and maintain it for a longer length of time, a controlled/sustained drug delivery system is primarily desired (Dash et al. 2010; Mohamed Rizwan and Damodharan, 2020). These systems create an efficient and well-tolerated concentration release per unit time from carriers, and the drug behaves like zero-order kinetics (Ammala, 2013). The qualities of the drug, additives, and polymers, as well as their ratio in composition and interactions between components (physical and/or chemical), could all have an impact on the drug release profile (Langer and Peppas, 1983; Terzopoulou et al., 2020). Depending on how the drug molecules are released from the delivery system, multiple subcategories of the controlled drug-release mechanism may exist. These can be enumerated as follows: degradation-controlled release, diffusion-controlled release, erosion-controlled release, osmotic

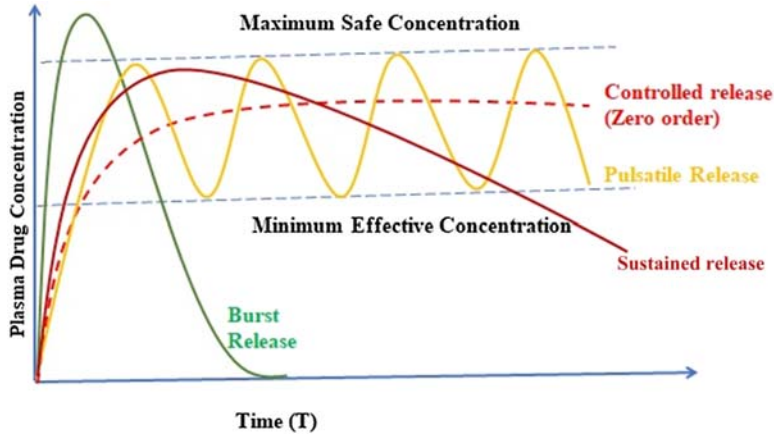

Figure 18.4 Plasma drug concentration—time curve for different release types.

pump-controlled release, and solvent-controlled release (Yun et al., 2015; Ammala, 2013; Blasi, 2019). Fig. 18.4 illustrates a plasma drug concentration versus time curve. Its shows the relation of release through burst of polymer, release in a controlled manner (zero order), sustained manner, and release in a pulsatile manner. Between the maximum safe concentration (MSC) and minimum effective concentration (MEC) there is the therapeutic range. A drug shows a toxic effect when the plasma concentration goes beyond the MSC and there is no therapeutic effect shown when the plasma concentration does not reach the MEC.

18.4.1 Dissolution controlled release

In dissolution controlled release, drugs are either coated or encapsulated within slowly dissolving polymers. These systems are mostly used in the production of enteric-coated dosage forms and drugs with high water solubility and dissolution rate. The steady-state dissolution process is described by the Noyes—Whitney equation. These formulations may be further divided into two types: matrix system (monolithic system) as in Fig. 18.5 and reservoir system (polymeric membrane) as in Fig. 18.6. In the matrix dissolution system, active pharmaceutical ingredients are uniformly distributed in the polymer matrix and molecules of API are released as the polymer matrix gets dissolved. In the reservoir system, drug molecules are coated or encapsulated by a rate-limiting polymer. The release of API molecules depends on the thickness and dissolution rate of the surrounding polymer membrane.

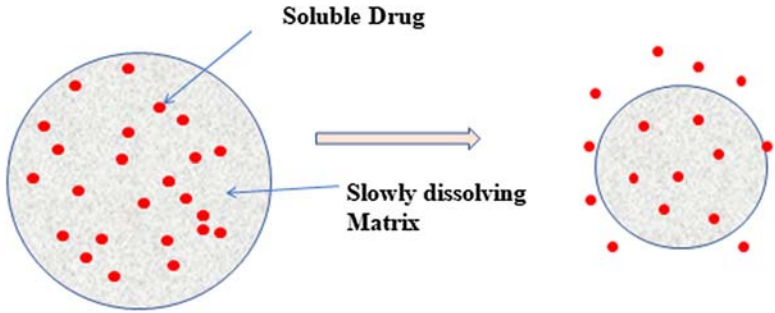

Figure 18.5 Drug release in the matrix system.

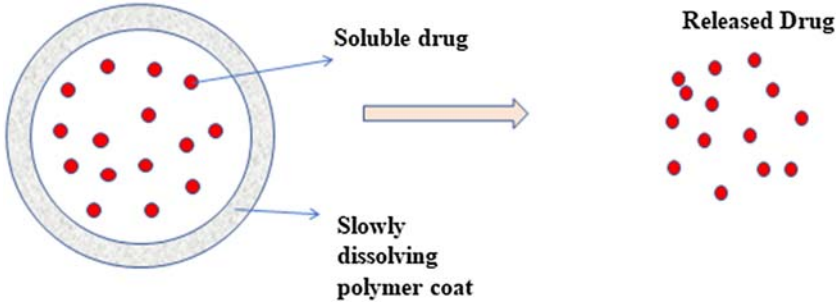

Figure 18.6 Drug release in the reservoir system.

18.4.2 Diffusion controlled-release

In a controlled-release system, drugs are mostly released through the diffusion method. In these systems, the drug is either dispersed within a polymeric matrix or encapsulated in it. Fig. 18.7 shows the release of drug through a diffusion mechanism where the drug is dissolved and dispersed in the polymer matrix. As per Fick's first law, the concentration gradient acts as a drive force for the movement of drug molecules through polymer matrices. Parameters including porosity, level of cross-linking, swelling behavior of polymers, and size of drug molecules play an important role in drug release (Alexis et al., 2004; Fu and Kao, 2010).

18.4.3 Degradation controlled release

This is the process by which polymers are broken down and the medicine is released at the needed location in the body. Polymer chains are split into oligomers and monomers during this process. Biodegradable polymers have linkages like ester and amide that may be broken down by enzymes or hydrolysis. Polymers are degraded to create physiologically acceptable

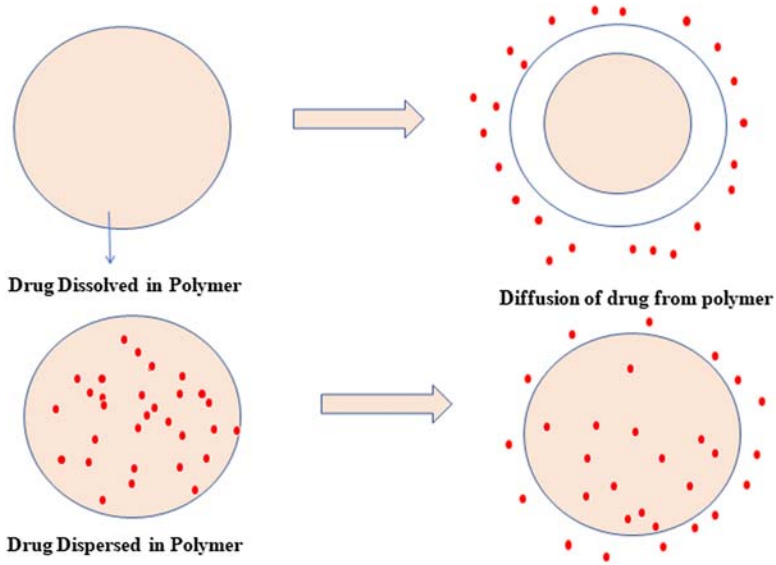

Figure 18.7 Release of drug through the diffusion mechanism.

agents, which are then eliminated from the body via a normal metabolic process. Surface and bulk degradation are the two types of deterioration (Fu and Kao, 2010).

18.4.4 Osmotic pumping release

Drug release can be controlled by application of one of the fundamental principles of biology: osmosis. A drug-delivery system which is based on osmosis can deliver drugs in an effective manner. In this system, osmotic pressure is created by the influx of water into a nonswelling system which is responsible for the transport of drug. Osmogens and semipermeable membranes are components in the design of an osmotically driven drug-delivery system (Amkraut et al., 1989; Conforti et al., 1996). A typical osmotic pump is shown in Fig. 18.8.

18.4.5 Erosion controlled release

The medicine is released in this sort of system as a result of the physical erosion/disintegration of polymers. Enzymes, hydrolysis, oxidation, or pH changes that lead to fragmentation can all contribute to polymer erosion. Polymers can experience either surface erosion (Fig. 18.9) or bulk erosion (Fig. 18.10), depending on the erosion mechanism (Hrkach and Langer, 2020). In surface erosion, polymers are degraded from the surface of the

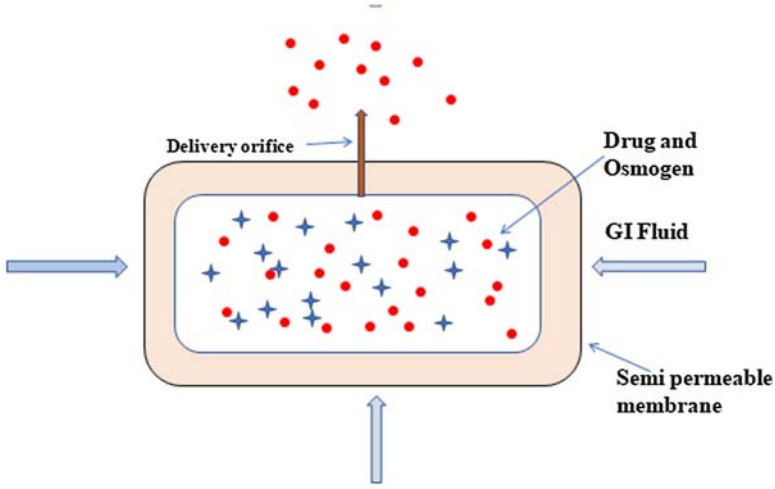

Figure 18.8 Release of drug through an osmotic pump.

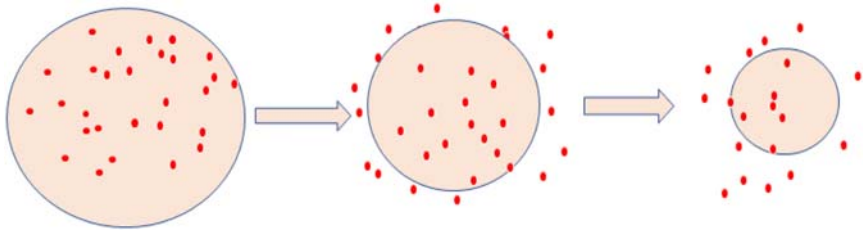

Figure 18.9 Release of drug through surface erosion polymer.

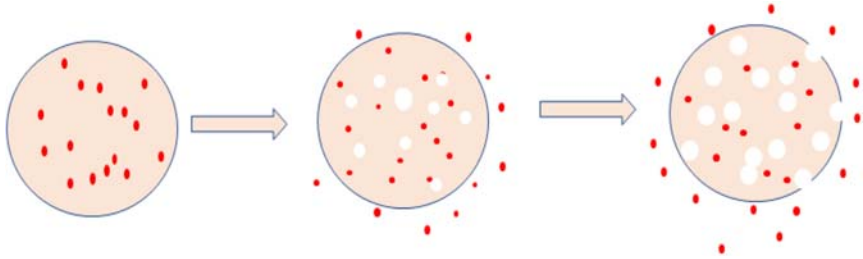

Figure 18.10 Release of drug through bulk erosion polymer.

matrix to the interior part, which occurs when the rate of erosion is greater than penetration of water in the system. When the rate of penetration of water is greater than the rate of erosion it results in bulk erosion where the whole matrix is starts to hydrolyze (Uhrich et al., 1999).

18.5 Release kinetic

Drug release kinetics depend upon the composition of the formulation, which includes the types of polymer, matrix system, method of preparation, and dissolution media. A kinetic model is further dependent upon the R^2 value. A zero-order kinetic model is used in controlled drug-delivery devices. Table 18.1 shows the release kinetic model with the respective equation which could be useful to evaluate the best-fitting model dependent upon the highest R^2 value.

18.6 Examples of commercially available biodegradable polymer base products

Several advantages over synthetic polymers make biodegradable polymers a choice for controlled drug delivery (Ammala, 2013). The theory of a drug-delivery system working in a controlled manner was introduced in 1952 as the sustained release formulation made by Smith Klein and during the first generation (1950–80) many oral and controlled releases were applied for clinical applications (Helfand and Cowen, 1983; Yun et al., 2015). Some of the commercial products available in the market are included in Table 18.2.

Table 18.1 Best-fitting models which are applied for kinetic release in drug delivery (Dash et al. 2010; Mohamed Rizwan and Damodharan, 2020).

S. no.	Kinetic model	Equation	Inference
1	Zero order	$WR = K0\ t \pm b$	Model with highest R^2 is consider as the best-fitting model
2	First order	$\ln (WL) = \ln W0 - K1\ t$	
3	Higuchi's model	$WR = K_H\ t^{1/2}$	
4	Korsmeyer–Peppas model	$\text{Log } (M_t/M\infty) = \log k + n \log t$	

Abbreviations: *WR*, quantity of drug released at the sampling time *t*; *WL*, quantity of drug remaining to be released at the sampling time *t*; *W0*, an initial quantity of drug; *K*, release rate constant of drug; *MT*, quantity of drug released up to time *t*; $M\infty$, total quantity of drug released up to time *t*.

Table 18.2 Examples of some commercially available products.

18.7 Conclusion

Controlled medication may be delivered, by choosing the appropriate biodegradable polymers, to the target organ or other sites. Synthetic or natural biodegradable polymers can increase the therapeutic effectiveness of drug-delivery systems. The future application of biodegradable polymers in the development of regulated medication delivery. The most often utilized polymers in nanoformulation currently are collagen, PLGA, and PLA. Future advancements in science and technology may result in the creation of a variety of these molecules that could be used as potential medication carriers. A recent advancement in nanotechnology has also enabled stabilizing revolutionary molecular imprinting and drug-delivery system creation. Continuous research in the area of nano-technology may lead to the creation of new opportunities for regulated and targeted medication delivery.

CHAPTER 19

Bioresorbable polymer-based sensors for medical applications

Thirumalaivasan Natesan[1], Senthilkumar Nangan[2] and Ramasubburayan Ramasamy[3]

[1]Department of Periodontics, Saveetha Dental College and Hospitals, Saveetha Institute of Medical and Technical Sciences (SIMATS), Saveetha University, Chennai, Tamil Nadu, India; [2]Department of Chemistry, Graphic Era (Deemed to be University), Dehradun, Uttarakhand, India; [3]Marine Biomedical Research Laboratory & Environmental Toxicology Unit, Department of Prosthodontics, Saveetha Dental College and Hospitals (SIMATS), Saveetha University, Chennai, Tamil Nadu, India

19.1 Introduction

The impact of bioresorbable polymer-based sensors on the medical technology landscape has been significant (Zhao et al., 2008; Arif et al., 2022; Ghaffari et al., 2021). These sensors offer real-time monitoring of physiological parameters, addressing issues with conventional sensors such as invasiveness and waste management. They are designed to be biocompatible and naturally degrade within the body, eliminating the need for secondary surgeries for removal (Kamrani and Fleck, 2019). Advancements in materials science, particularly bioresorbable polymers, drive their development. Bioresorbable polymers undergo a two-phase degradation process in the body, breaking down into fragments and then being metabolized by cellular mechanisms. This process is utilized to create sensors that can be implanted, function, and dissolve naturally, reducing complications (Sahandi Zangabad et al., 2023; Feng et al., 2022). These polymers enhance sensor functionalities and extend operational lifespan in the body. They offer benefits such as reduced infection risks, targeted treatment, and environmental sustainability.

Introduced in the 1970s, bioresorbable polymers have evolved in medical applications, including sutures made of materials like poly(glycolic acid), poly(lactic acid), and polydioxanone. Incorporating them into sensors presents challenges in biocompatibility and controlled degradation (Allizond et al., 2022). Customization requires knowledge of material science, sensor design, and biology. Bioresorbable sensors offer continuous

Bioresorbable Polymers and their Composites

monitoring without surgical removal, improving patient experience (Ashammakhi et al., 2021; Nie et al., 2022). However, challenges like biocompatibility must be addressed for wider adoption. This chapter discusses bioresorbable polymer-based sensors, emphasizing their adaptability in healthcare. It explores their use in drug-delivery systems, with degradation rate influencing release kinetics. The sensors also address sustainability concerns by being biodegradable, offering an eco-friendly alternative to nonbiodegradable sensors (Won et al., 2021; Morsada et al., 2021; Islam et al., 2022).

The topics that are covered in this chapter include: (i) the essential principles of biodegradable polymers and their pertinent physiochemical attributes for medical utilization, (ii) a comprehensive review of current biodegradable sensing devices, classified according to their healthcare functionalities such as cardiac surveillance, glycemic level monitoring, and ophthalmic pressure assessment, (iii) a synopsis of the manufacturing methodologies employed in crafting sensors based on biodegradable polymers, (iv) mechanical sensing devices, and (v) analytical sensing devices.

19.2 The essential principles of biodegradable polymers and their pertinent physiochemical attributes for medical utilization

The medical technology sector is currently experiencing significant changes, largely attributable to the emergence of bioresorbable polymers. These materials are engineered to naturally disintegrate within the human body (Luzi et al., 2019). Their unique physiological and chemical traits make them essential for various medical uses. Therefore, gaining an in-depth comprehension of bioresorbable polymers and their physicochemical attributes is vital for both scholars in the field and healthcare professionals (Karade et al., 2021). To begin with the foundational concepts, bioresorbable polymers consist of extended molecular chains that the body can metabolize through its own physiological processes. These polymers often contain ester, ether, or anhydride linkages that are prone to hydrolytic breakdown (González et al., 2023; Xu et al., 2023). This hydrolysis leads to their eventual transformation into simpler compounds like water and carbon dioxide, which are then naturally eliminated from the body. This feature of being metabolizable distinguishes them sharply from nonbioresorbable materials such as metals, which persist within the body unless they are surgically extracted (Lin et al., 2023).

In contemporary healthcare applications, bioresorbable polymers have emerged as a focal point of interest, thanks in part to their distinct physicochemical attributes. This section offers a foundational understanding of these polymers and their significance in medical settings. Known for their ability to biologically decompose over a specific time frame, bioresorbable polymers negate the requirement for surgical extraction (Zielińska et al., 2023; Aguirre et al., 2023). This characteristic renders them highly applicable across various medical domains, such as controlled drug release, tissue scaffolding, and implantable medical equipment. A deeper understanding of their physicochemical traits, including degradation rates, mechanical stability, biocompatibility, and tissue interactions, is imperative to harness their full capabilities (Johansson et al., 2023). Through such insights, bioresorbable polymers hold the promise to transform the future of medical procedures and technologies. This section aims to offer an exhaustive exploration of the foundational elements and attributes of bioresorbable polymers, highlighting their potential utility and setting the stage for future innovations in medical science and engineering (Gandla et al., 2023).

Dissolvable sensors are emerging as critical tools in healthcare diagnostics and monitoring, showcasing advantages over their nondissolvable counterparts. These sensors are biologically safe, minimize environmental waste, and allow for distant tracking without requiring surgical removal (Ziesmer, 2023). This section organizes such sensors into categories based on their applications in healthcare, such as heart monitoring, glucose level assessment, and eye pressure tracking. The integration of these sensors is transformative for medical practices, enabling real-time data collection within the body and posing minimal environmental risks due to their biodegradable nature (Monge et al., 2023). This chapter outlines the various applications of dissolvable sensors, emphasizing their role in modern healthcare. These sensors are an innovative development, resolving issues related to implant removal and reducing medical waste. Their versatility makes them invaluable assets in healthcare, adaptable to specific needs, materials, and functionalities (Ramezani and Mohd Ripin, 2023; Tovar-Lopez, 2023).

The field of medical technology is undergoing significant changes, largely facilitated by the advent of bioresorbable polymers. These are materials engineered to naturally break down within the human body and exhibit characteristics that make them highly desirable for medical use (Aziz et al., 2023). A deep understanding of the core elements and physicochemical properties of these polymers is essential for both scholars in

the field and healthcare professionals. Bioresorbable polymers are complex molecular constructs that can be naturally processed by the body. They often contain bonds like esters, ethers, or anhydrides, which are prone to hydrolytic reactions (Sharma and Shankar, 2023). Through hydrolysis, these materials decompose into simpler compounds such as water and carbon dioxide, which are easily eliminated from the body. This is in stark contrast to nonbioresorbable materials like metals, which remain in the body unless they are physically removed. The physicochemical attributes of these bioresorbable polymers are influenced by various factors. For instance, molecular weight plays a significant role; polymers with higher molecular weights usually exhibit slower rates of degradation and greater stability. This makes them well-suited for long-term medical applications, such as bone implants. Additionally, the affinity of these polymers for water—whether they are hydrophilic or hydrophobic—also affects their rate of degradation. Hydrophilic polymers tend to break down more quickly due to increased water absorption, making them ideal for short-term uses such as drug-delivery systems. On the other hand, hydrophobic polymers are more suitable for applications requiring a slower degradation rate (Li et al., 2023; Giubilini et al., 2023).

The degree of crystallinity in polymers is a crucial factor; polymers with semicrystalline structures exhibit enhanced mechanical resilience, yet their rate of decomposition is slower due to the closely packed molecular formations. The glass transition temperature, which signifies the change from a glass-like to an elastic state, influences both the material's mechanical properties and its rate of degradation. Attributes like tensile strength, elasticity, and the ability to withstand compression are especially relevant in applications requiring load-bearing capacity, such as orthopedic implants. Various techniques like copolymerization, blending, or the introduction of additives allow for the fine-tuning of these features (Kim et al., 2023). Striking a balance between the material's mechanical capabilities and its rate of degradation is a complex, yet crucial, consideration in the development of polymers for medical usage.

In the realm of medication delivery, the dynamics governing how a healing compound is released from a polymer framework are critical. These dynamics are shaped by both how quickly the polymer breaks down and the diffusion characteristics of the drug. Certain polymers can be engineered to react to external signals such as temperature fluctuations or changes in acidity, facilitating precise regulation of medication release. In addition, the external attributes of the polymer play a significant role in its biocompatibility,

affecting how cells adhere and grow on it. Adjusting variables like surface texture, electrical charge, and chemical functionalities can either promote integration with bodily tissues or reduce bacterial attachment, depending on the medical objective (Pourmadadi et al., 2023; Princen et al., 2023). It is also crucial to ensure that any substances produced during the polymer's breakdown in the body are harmless and can be either metabolized or expelled easily. Understanding how these breakdown products are processed by the body is therefore a key consideration in selecting and designing polymers that are absorbed back into the body after serving their purpose. For example, polymers like polylactic acid (PLA) break down into lactic acid, a substance naturally found in the body, thus minimizing risks related to toxicity. Additionally, the method used to sterilize the polymer must be compatible; autoclaving may not be suitable for all such polymers, as it could alter their molecular structure and overall properties. On an ecological note, the ability of these polymers to biodegrade naturally helps to mitigate the issue of medical waste, setting them apart from traditional, nonbiodegradable materials (Lérida-Viso et al., 2023).

In essence, the various physical and chemical properties of biodegradable polymers, including factors like molecular mass, affinity for water, structural organization, mechanical features, rate of decomposition, and compatibility with biological systems, are crucial for their applications in healthcare. A deep grasp of these core attributes provides a foundation for improving both the effectiveness and the safety of medical devices, pharmaceutical delivery systems, and scaffolds for tissue regeneration (Priya et al., 2023; Sharma et al., 2023). As a result, in-depth scholarly research and stringent clinical evaluations are indispensable for unlocking the full potential of these innovative substances in the medical field.

19.3 A comprehensive review of current biodegradable sensing devices, classified according to their healthcare functionalities such as cardiac surveillance, glycemic level monitoring, and ophthalmic pressure assessment

The emergence of sensors that can be naturally absorbed by the body marks a transformative moment in medical diagnostic and surveillance technologies. Made from materials that are not only compatible with biological systems but also capable of breaking down naturally, these

devices offer the convenience of continuous data monitoring without necessitating additional surgeries for their removal (Munirathinam et al., 2023). This section offers an exhaustive review of these absorbable sensors, organizing them according to specific medical uses such as heart rate monitoring, blood sugar level tracking, and measuring pressure within the eye. For each category, detailed discussions are provided to explain the operational principles, constituent materials, and technologies that these sensors employ (Shen et al., 2023; Govindasamy and Thirumalaivasan). Furthermore, the chapter incorporates comparative assessments to outline the strengths and weaknesses of different kinds of sensors.

Advancements in medical technology have significantly elevated the standard of healthcare by facilitating early detection and continuous monitoring for optimized therapies. Sensors that are bioresorbable are particularly noteworthy, as they are both biocompatible and temporary, dissolving over a period of time to mitigate risks such as infections. This section provides a comprehensive examination of these sensors, organizing them based on their use-cases, such as monitoring heart activity, measuring blood sugar levels, and assessing intraocular pressure (Hosseini et al., 2021; Dash et al., 2019). This systematic categorization serves as a guide for healthcare practitioners to choose the most suitable sensors, while also highlighting existing obstacles and prospective advancements.

19.3.1 Cardiac monitoring

Innovations in bioresorbable sensors have led to a new era for heart monitoring, offering advantages not available with conventional implantable devices. Typically made from eco-friendly materials like polylactic acid (PLA) and polyglycolic acid (PGA), these sensors are constructed to decompose naturally within the human body, eliminating the necessity for surgical removal (Shanmugam et al., 2023). These sensors are adept at capturing crucial heart-related metrics such as electrical patterns and variations in heart rate, providing a holistic assessment of cardiovascular health. Additionally, they can be designed to deliver medications in a regulated fashion, thereby augmenting existing treatment methods. When placed in proximity to the heart, these devices track essential cardiovascular data such as heart rate and blood flow, eventually disintegrating naturally to avoid any further surgical procedures. Some of these cutting-edge sensors come with multifunctional capabilities, allowing for both the dispensation of medication and real-time tracking of cardiac functions, leading to a more cohesive treatment plan (Teijido et al., 2023). All in all, the emergence of

bioresorbable sensors has revolutionized the monitoring and treatment of heart-related disorders by providing real-time, minimally invasive options facilitated by materials that are biologically degradable, like PLA and PGA.

19.3.2 Blood glucose sensing

Implantable sensors made from materials that naturally degrade have revolutionized the field of diabetes management by offering a noninvasive, user-oriented solution for continuous blood sugar measurement. Unlike traditional glucose monitoring methods that require frequent finger pricking, these implantable sensors are placed beneath the skin and provide uninterrupted monitoring capabilities. Fabricated from materials like biodegradable polymers and soluble conductive materials, these sensors naturally disintegrate over time, eliminating the need for surgical removal. Constant monitoring of blood glucose levels is often challenging with existing technologies; however, these degradable sensors offer an appealing alternative (Zhu et al., 2023; Anand, 2023). They allow for subcutaneous implantation and wirelessly transmit data to external devices for immediate assessment. Some advanced models can even deliver insulin, acting as an artificial pancreas. The inherent biodegradability of these sensors circumvents the need for surgical extraction, providing a lasting solution for diabetes management. Moreover, these cutting-edge sensors address a key challenge in diabetes care: the discomfort and hassle associated with frequent blood tests. They employ enzyme-based electrochemical detection techniques, anchoring enzymes like glucose oxidase onto biodegradable platforms such as chitosan (Wang et al., 2023a; Bilal et al., 2023). This allows for accurate and targeted glucose detection, while the sensor naturally disintegrates after a set period. Consequently, these sensors enhance patient compliance and contribute to an overall improvement in their quality of life.

19.3.3 Intraocular pressure measurement

Consistent monitoring of intraocular pressure (IOP) is crucial for the effective management of glaucoma. Bioabsorbable sensors offer an advantageous means for such surveillance. In contrast to conventional techniques that often involve invasive procedures and yield periodic data, these sensors provide constant measurements and are designed to naturally break down after implantation. Created from biocompatible substances like polycaprolactone (PCL), the sensors are minimally intrusive while remaining highly compatible with biological tissues. Utilizing state-of-the-art materials such as bioabsorbable silicon and hydrogels, the sensors have appropriate

mechanical properties and undergo a regulated disintegration process (Liu et al., 2023a; Venkatesan et al., 2023). These devices offer a more convenient alternative to irregular and often uncomfortable hospital visits, as they can be embedded within the eye to enable continuous remote IOP tracking and timely clinical interventions. Capable of detecting pressure changes, these sensors ultimately disintegrate without inducing any adverse effects, allowing for more accurate modifications in the glaucoma treatment regimen (Molaei et al., 2018).

Dissolvable sensors represent a revolutionary step forward in medical diagnostic and monitoring technology, acting as an eco-friendly alternative to conventional sensors while also reducing electronic pollution. Utilized across a wide spectrum of healthcare uses from monitoring heart activity to measuring blood sugar levels and evaluating eye pressure, these sensors are integral to a more patient-centric model of healthcare. Benefiting from the latest developments in materials science, these sensors fulfill a range of medical necessities and simultaneously tackle environmental degradation through their ability to break down naturally. Although significant strides have been made, challenges persist in optimizing sensor longevity, data precision, and biological compatibility (Molaei et al., 2018; Nan et al., 2023; Nangan et al., 2023). By providing cutting-edge, eco-conscious, and patient-oriented solutions, dissolvable sensors are paving the way for advanced medical monitoring systems. This summary outlines the current range of uses and aspires to galvanize additional scholarly investigation into this burgeoning area.

19.4 An overview of the fabrication techniques for bioresorbable polymer-based sensors

Biodegradable sensors made from polymers are gaining attention for their applications in healthcare diagnostics, pharmaceutical delivery, and environmental monitoring. These sensors are environmentally responsible as they decompose naturally, thereby reducing electronic waste and providing a sustainable option. The effectiveness of these devices is closely tied to the manufacturing processes employed. This section aims to comprehensively assess the various production methods that are essential for improving the functionality and performance of such sensors (Yang et al., 2022). The field of sensors made from polymers that can be naturally broken down by the body has experienced significant expansion lately, paving the way for novel healthcare applications including drug delivery and ongoing monitoring of

vital signs. One distinctive advantage is that these materials degrade naturally, obviating the need for additional surgeries to remove them, which consequently reduces the long-term health implications. The cornerstone of their adaptability and efficacy is primarily rooted in the manufacturing processes used.

The increasing significance of sensors made from bioresorbable polymers in the medical field is paving the way for advanced scientific inquiries. These devices, compatible with biological systems, offer considerable advantages such as eliminating the requirement for subsequent surgeries and reducing risks commonly linked with implanted mechanisms. However, ample opportunities exist for ongoing research aimed at enhancing their performance features and diversifying their use-cases (La Mattina et al., 2020). The rapidly advancing field of sensors made from bioresorbable polymers has captured considerable attention in healthcare circles. These insertable instruments have a variety of functions, including continuous health surveillance and medication delivery, and they are organically metabolized by the body over a period of time. While they offer numerous inherent benefits such as a lower risk of infection and eliminating the necessity for surgical removal, there remain unexplored areas of research that could enhance their performance and extend their applications in healthcare settings (Boutry et al., 2012). This section seeks to explore these potential areas of study, focusing specifically on groundbreaking technological developments that could transform the domain of medical sensors.

19.4.1 Solvent casting

One of the earliest and simplest approaches is solvent casting, which finds frequent application in producing flat, film-like structures. In this method, an organic solvent is utilized to dissolve a polymer, followed by the introduction of active components such as therapeutic agents or sensing elements. After thorough mixing, the solution is poured onto a mold and allowed to undergo evaporation, resulting in the formation of a solidified film. Although straightforward in execution, solvent casting often gives rise to uneven component distribution, thereby restricting its utility in intricate devices (Beygisangchin et al., 2021). Solvent casting represents a direct and cost-effective strategy for manufacturing bioresorbable sensors. In this procedure, the polymer is initially dissolved within a suitable solvent to create a uniform solution. This liquid is subsequently cast into a mold resembling the desired sensor configuration, followed by solvent evaporation, culminating in the development of a solidified framework.

This method permits a notable level of customization; however, it may necessitate the use of harmful solvents that require complete evaporation (Revia et al., 2022; Lu et al., 2023).

Among the widely employed fabrication methodologies, solvent casting stands out as a prominent technique. This process involves dissolving the polymer in a suitable solvent and then casting it into a mold to achieve the desired shape. Once the solvent undergoes evaporation, the polymer solidifies and can be integrated with other sensor components (Borbolla-Jiménez et al., 2023). Solvent casting's popularity stems from its simplicity, although it does have limitations regarding the complexity of structures that can be effectively produced.

19.4.2 Electrospinning

Electrospinning stands as a widely employed method, particularly for the production of fibrous structures. This technique involves expelling a polymer solution through a syringe under the application of high voltage, resulting in the formation of micro- or nanofibers. These fibers can subsequently be manipulated or aligned into specific arrangements, offering significant benefits for sensing applications that necessitate ample surface area. The principle underlying electrospinning is rooted in harnessing electrical forces to generate fibers from a polymer solution or melt. By supplying a high voltage, the polymer solution becomes charged, forming what is known as a Taylor cone. As droplets emerge from this cone, they move toward a collector that is grounded, undergoing solidification in the process, thus transforming into fibers (Naveenkumar et al., 2023; Cao et al., 2023). This technique proves particularly proficient in crafting nanofibrous sensors, which exhibit a heightened surface area and expedited biodegradation. Electrospinning enables the creation of nanofibers, which boast remarkable surface-to-volume ratios, thereby enhancing the sensitivity of sensors. Through the application of an electric field, a polymer solution is expelled via a needle, yielding delicate fibers that accumulate on a grounded surface. Despite its advantages, electrospinning demands specialized equipment and can consume significant amounts of energy (Chakrapani et al., 2023). Nonetheless, it allows for the incorporation of diverse functional components into the polymer matrix, expanding its range of potential applications.

19.4.3 3D printing

The emergence of 3D printing technologies has facilitated the manufacturing of intricate shapes with a remarkable level of accuracy. The selection of 3D

printing method, whether it is fused deposition modeling (FDM) or stereolithography (SLA), dictates the compatibility with different types of polymer materials. This approach offers substantial customization options and is well-suited for swift prototyping, albeit with some constraints on material choices due to printer limitations. The utilization of additive manufacturing methods, such as 3D printing, has also been adapted for crafting bioresorbable sensors (Shilar et al., 2023). Leveraging meticulous precision and step-by-step assembly, 3D printing empowers the generation of intricate shapes and internal configurations. This technique proves particularly advantageous for tailoring designs to specific patients or customized applications. However, it requires advanced design software and can be time-intensive for large-scale production. Recent progressions in 3D printing technology have elevated its popularity as a means to produce bioresorbable sensors. This technique facilitates the creation of intricate three-dimensional structures that can be precisely customized for distinct purposes (Dew, 2023). Furthermore, 3D printing expedites prototype development, enabling faster cycles of iteration in the design process.

19.4.4 Photolithography

Photolithography, a fundamental process in microfabrication, utilizes ultraviolet (UV) light in conjunction with a photosensitive material to delineate intricate geometric configurations onto a substrate. In the realm of bioresorbable sensors, the utilization of photolithography enables the creation of complex structures possessing remarkable spatial resolution. This characteristic is indispensable for the production of diminutive implantable devices. Initially conceived as a technique for semiconductor manufacturing, photolithography has been ingeniously modified to cater to the demands of bioresorbable sensor fabrication (CS and Kandasubramanian, 2023). The methodology encompasses the deposition of a photosensitive polymer layer onto the substrate, which is subsequently subjected to UV exposure through a mask. Following this exposure, a development process ensues wherein the regions that were illuminated are selectively removed. This meticulous procedure culminates in the preservation of an exacting pattern on the substrate (Wang et al., 2023b). It is worth noting that the precision achieved through this approach is exceptional; however, its implementation can incur substantial costs. Consequently, its application is primarily tailored to scenarios demanding intricate patterns and uncompromising precision on a smaller scale.

Photolithography stands as a sophisticated technique that affords the capability to intricately pattern sensor constituents onto a polymer substrate. By utilizing UV light to induce chemical modifications in the photosensitive polymer layer, a template of intricate designs is rendered (Alowakennu et al., 2023). While this method is conventionally associated with the semiconductor industry, its adaptation to bioresorbable polymers underscores its versatility and pertinence in the context of emerging technologies.

19.4.5 Coating and layering techniques

This approach encompasses the sequential application of positively and negatively charged polymers onto a surface, achieved through electrostatic interactions. This process offers meticulous management over thickness and composition, enabling the integration of diverse functional materials into the sensor. Nonetheless, while effective, this method can require significant labor and is influenced by environmental factors such as pH and ionic strength. The procedure entails the successive deposition of polyelectrolytes with opposing charges onto a substrate (Kogularasu et al., 2023). This technique empowers precise manipulation of the sensor's thickness and accommodates multiple layers of distinct materials. This proves beneficial in intricate drug-delivery scenarios where varying release patterns are sought after. Coating methodologies often complement alternative fabrication techniques (Qureshi and Niazi, 2023). For instance, a sensor might undergo fabrication using photolithography, followed by a coating of biocompatible material through chemical vapor deposition. Layering approaches serve to introduce supplementary functionalities, such as coatings that respond selectively to particular biological markers.

The field of bioresorbable polymer-based sensor fabrication faces various challenges, including scalability, cost-effectiveness, and the integration of functional elements without compromising biocompatibility or performance. Advances in nanotechnology, material science, and computational modeling are expected to significantly impact future developments. Despite the advances in fabrication techniques, challenges remain in terms of scalability, reproducibility, and the integration of multiple functionalities within a single sensor (Pathak et al., 2023). Further research is needed to develop more efficient fabrication methods that can meet the growing demands for more sophisticated sensing capabilities.

The fabrication methods employed for bioresorbable polymer-based sensors encompass a diverse array, each offering distinct advantages and

limitations. Gaining a comprehensive grasp of these techniques stands as a pivotal factor in propelling the technology forward and broadening its applications within healthcare and other domains. As the field continues to mature, it is foreseeable that novel methodologies and hybrid approaches will come to the forefront, thereby paving the way for bioresorbable sensors that are more efficacious and versatile in nature. To summarize, the techniques used in fabricating bioresorbable polymer-based sensors exhibit diversity, with each method conferring unique benefits and challenges. The selection of a specific approach frequently hinges upon the intended application, material attributes, and the desired traits of the sensor (Ligon et al., 2017). The ongoing pursuit of research endeavors serves to continually innovate these techniques, aiming to enhance the functional aspects, scalability, and biocompatibility of these groundbreaking devices.

In conclusion, the potential harbored by bioresorbable polymer-based sensors for revolutionizing medical diagnostics and treatment is substantial. The trajectory of future research in this realm encompasses a multidimensional scope, necessitating an interdisciplinary approach that involves domains such as materials science, computer science, engineering, and ethical considerations. With the persistent advancement of technology, the outlook is promising for these transient, biocompatible devices to assume an increasingly pivotal role in healthcare, thereby significantly elevating patient outcomes and overall medical efficiency.

19.5 Physical sensors

Monitoring physiological conditions within the human body is significantly facilitated by the use of pressure and strain sensors. For healthcare surveillance, sensors with degradable materials and capacitive configurations have been engineered. These innovative sensors have uses in various domains, including electronic skin technology and malleable robotics. They employ a variety of structural designs that make use of disintegrable dielectric substances, as well as piezoelectric, piezocapacitive, and piezoresistive components. These monitoring devices are carefully positioned in specific body parts such as the brain, eyes, and muscles, primarily to mitigate the risks associated with elevated intracranial pressure following surgical interventions. As a case in point, a cordless sensor made of biodegradable materials was developed using principles of resonant frequency. This particular sensor featured zinc and iron bilayers, electrodeposited to function as conductive parallel plates. These conductive plates were distanced by

a layer of poly-L-lactic acid (PLLA) and sealed within a shell of polycaprolactone (PCL) (Banitaba et al., 2023). Air within the sensor interacted with a meticulously designed inductor coil. When external pressure impacted the sensor, the spacing within its capacitive assembly was reduced, causing a detectable alteration in the circuit's resonant frequency. This shift was remotely observed through an external coil situated outside the human body.

The transducer displayed a frequency reaction that corresponded linearly with the pressure exerted upon it. Sensitivity metrics were roughly gauged at 290 kHz/kPa over a span of 0–20 kPa. For assessing long-term reliability, the sensor was tested in an isotonic sodium chloride solution. Initial findings suggest that the sensor operated effectively for close to 107 h in this environment, eventually breaking down fully near the 170-hour mark. This pioneering technique in crafting biodegradable pressure-sensitive devices offers noteworthy advantages for noninvasive healthcare diagnostics and shows promise for future medical applications (Stewart et al., 2018). In a different but related vein, a pressure-sensitive device engineered for internal bodily placement has been introduced. This sensor is particularly designed for physiological pressure tracking in diverse body organs such as the brain, lungs, eyes, and heart. Its main constituent is piezoelectric poly(L-lactic acid) (PLLA), which gains its piezoelectric characteristics through thermal processing under mechanical stress to realign the polymer structures. Following this, the film undergoes precise sectioning to further optimize its piezoelectric characteristics. The architecture of the sensor includes dual layers of the piezoelectric PLLA material, sandwiched between miniature biodegradable Mo/Mg electrodes. These components are encased in layers of polylactic acid (PLA). The sensor's performance metrics are notable, capable of identifying minor variances in pressure in the range of 0–18 kPa. It manifests two separate sensitivity thresholds: the first is 75 mV/kPa for the 0–2 kPa pressure interval, and the second is 14 mV/kPa for the 3–18 kPa range. Importantly, the sensor's sensitivity can be calibrated by manipulating the number of PLLA layers used in its construction (Annese et al., 2014).

The sensor exhibits stable functionality by operating continuously for roughly 4 days in both regulated laboratory conditions with a 37°C phosphate-buffered saline (PBS) solution and a pH level of 7.4, as well as when it is surgically positioned in the back region of mice. Following this period, the sensor begins its process of deterioration, culminating in its complete dissolution. The entire disintegration process for the sensor takes

approximately 8 days, although full decomposition takes several weeks. In this context, the importance of the thickness of the sensor's casing made of polylactic acid (PLA) is highlighted as it plays a crucial role in affecting the speed of the sensor's breakdown (Lee et al., 2022). A separate example of a biodegradable pressure sensor is a single-use capacitive patch designed for heart rate monitoring. This particular sensor employs a dielectric layer made of poly(glycerol sebacate) (PGS) with a microstructured design, and this layer is sandwiched between two magnesium-based electrodes to form the capacitive system.

A novel methodology was used to create a biodegradable sensing device by leveraging POMaC and PHB/PHV materials, each with a 10 μm thickness, as well as a PLLA-based coiled spacer. The sensor was designed to wrap around a rat's femoral artery, situating the softer POMaC layer in contact with the vessel for a minimally invasive mechanical link to the arterial wall. The operational performance of the sensing device relied on changes in capacitance, which were detected in the picoFarad range. These changes were generated by the expansion and contraction of blood vessels. Such fluctuations led to alterations in the resonant frequency of an LCR electrical circuit, which could be remotely detected via a coupling mechanism with an external reading coil (Chen and Wang, 2002). Approximately 1 week after implantation, a noticeable reduction in the sensor's signal was recorded.

In a noteworthy development, Boutry and colleagues made substantial contributions to the field of biodegradable and implantable sensors with capacitive functionalities. The sensor is ingeniously engineered to enable real-time assessments of mechanical stresses on tendons as well as the deformation experienced by tissue post-surgery. The design of the sensor is versatile, allowing it to expand and thus simultaneously record both strain and pressure metrics during the healing of tendons. The device is built as a dual-layered system. The first layer features a specialized dielectric layer made of PGS, combined with magnesium (Mg) electrodes, which is focused on pressure measurement (Ruth and Bao, 2020). The second layer employs a different configuration, using interlocking Mg electrodes mounted on a PLLA base to capture strain data.

Evaluating the in vitro breakdown characteristics involved immersing the sensing apparatus in a saline solution buffered to a pH of 7.4, and maintained at a temperature of 37°C. In this setting, the apparatus exhibited consistent functionality over a 2–3-week period. When implanted into the dorsum of a rodent, the device continued to deliver reliable readings for

more than 3.5 weeks. Remarkably, the sensing mechanism displayed quick reaction times within the scope of milliseconds and excellent sensitivity, with the capability to sense as low as 0.4% strain and pressure comparable to the force generated by a single salt grain (12 Pa). A key feature of this sensing design is its ability to combine both pressure and strain metrics without the need for a separate interface (Guex et al., 2021). This innovation offers the possibility for tailored rehabilitation plans suited to individual needs.

A pressure sensor constructed from sustainable materials, namely a combination of glycine amino acid and chitosan polymer, has been designed for applications in wearables, such as for use beneath wound dressings to track pressure fluctuations. The creation process utilized electron-beam evaporation to apply gold electrodes to both surfaces of the glycine–chitosan film, adhering to a thickness standard of 10/90 nm (Hosseini et al., 2020). The sensor demonstrated a sensitivity of 2.82 ± 0.2 mV per kPa and was effective within a pressure range of 5–60 kPa. To evaluate its biodegradability, electrodes made of magnesium (Mg) were integrated into the sensor. These electrodes completely broke down when submerged in a phosphate-buffered saline solution with a pH level of 7.4, followed by the gradual dissolution of the remaining film material in subsequent days. The addition of chitosan to the composite not only improved the film's flexibility but also influenced the crystallization of glycine into its β-phase, a form known for its elevated piezoelectric constant.

In the realm of healthcare surveillance, thermal sensors are indispensable for both immediate and distance-based assessments of bodily heat levels. These instruments are especially effective for keeping track of temperatures within the brain and at wound sites, the latter of which is an indicator for potential infection. Generally, these sensors operate on the principle of piezoresistive compounds, leveraging the intrinsic relationship between electrical resistance and temperature. Two primary categories of sensor behavior exist: those with a positive temperature coefficient (PTC), where an uptick in temperature leads to higher resistance, and those with a negative temperature coefficient (NTC), where resistance dwindles as temperature ascends. PTC-based sensors are commonly employed in functions such as safeguarding against excess electrical current, self-adjusting heating systems, and miniature switch sensors (Liu et al., 2023b; Steinegger et al., 2020). On the other hand, NTC-based materials are apt for creating highly flexible thermistors that are incorporated into

wearable devices for thermal sensing, spatial temperature distribution, and thermal adjustments.

In a self-directed scientific investigation focusing on eco-friendly electronic devices, researchers employed the technique of femtosecond laser direct writing (FsLDW) to create unique graphene formations on organic materials such as leaves and wood. Using ultraviolet femtosecond lasers, they were able to concentrate heat production, which resulted in the carbonization of the components within the wood (Lee et al., 2023). Through repeated carbonization processes, distinctive laser-induced graphene patterns were successfully achieved. A prototype temperature sensor was constructed on a dried leaf that had an estimated thickness of 100 μm. This sensor exhibited a negative temperature coefficient of −0.08% per degree Celsius. In a similar manner, a related sensor was developed on a wooden surface, showing results comparable to the leaf-based sensor but with a longer response and recovery time.

In a novel scientific study, researchers engineered an eco-friendly photonic device capable of measuring factors such as tissue oxygen levels, temperature, and neuronal activity. The device was constructed with materials that are biologically absorbable, encompassing silicon-based unijunction light detectors, tricolor sensors with silicon P—N junctions, a layered optical filter, and optical fibers composed of poly(lactic-co-glycolic acid) (PLGA). To analyze the concentrations of silicon and zinc in various mouse tissues over a period of 7 days, analytical techniques such as inductively coupled plasma optical emission spectrometry (ICP-OES) and inductively coupled plasma mass spectrometry (ICP-MS) were employed (Hassan et al., 2023). The initial findings indicated an uptick in the levels of these elements in the kidneys, pointing toward renal elimination as the likely excretion pathway. Moreover, the device's light sensor, based on a silicon nanomembrane, was observed to fully break down within 2 weeks when immersed in a phosphate-buffered saline solution maintained at 37°C. The sensor's temperature-sensitive resistance allowed for precise monitoring of tissue temperature fluctuations, achieving a resolution nearly as accurate as 0.1°C.

Recent progress in optical sensor technology has concentrated on the continuous monitoring of pressure and temperature within the skull. The sensor is engineered to detect variations in the size of air pockets or alterations in the properties of photonic crystal arrays. These changes are triggered by the pressure-driven movements of the silicon nitride monolayer (Si-NM) diaphragm. Such movements cause a shift in the resonant

peak located in the reflection spectrum. The same sensor configuration is also capable of assessing temperature changes by observing alterations in the refractive index of silicon (Zhang et al., 2015). Notably, the sensor exhibited a temperature response rate of 0.090 nm per degree Celsius and a sensitivity to pressure changes at 3.8 nm per mmHg. When subjected to a PBS solution at a temperature of 37°C, the sensor was observed to completely disintegrate in approximately 195 days.

19.6 Chemical sensors

Chemical detection instruments are crucial for gathering information from biological markers in the human body, enabling the instantaneous and nonintrusive tracking of health metrics such as sugar concentration, acid–base equilibrium, levels of nitric oxide, and assorted ions. While studies have successfully shown that eco-friendly, biodegradable sensors can perform as well as their nonbiodegradable equivalents, there is a noticeable absence of exhaustive studies that focus on the creation and effectiveness of these biodegradable chemical sensors in ongoing healthcare monitoring scenarios. Addressing the obstacles in developing such sensors requires ensuring their operational integrity in physiological conditions without the need for protective casings, as well as their precise identification of targeted chemicals, even in the presence of other biologically active substances (Li and Wen, 2020).

Recent strides have been made in surmounting multiple obstacles in the field of sensor technology. One notable breakthrough has been the development of an electrochemical sensor strip composed of chitosan that is capable of dopamine detection. This device utilizes elements like chitosan, along with reduced graphene oxide and graphene, to enhance its sensitivity. This optimizes the sensor to identify dopamine concentrations as minimal as 10 ppm, making it well-suited for internal bodily applications. In another independent research endeavor, a humidity sensor was crafted using environmentally sustainable and biodegradable materials, particularly polysaccharides. The construction involved the layering of a chitosan–lignin blend in a 9:1 ratio onto a flexible PI substrate through spin-coating methods. This resulted in a sensor layer with an approximate thickness of 20 μm (Prabhu et al., 2022). Once Mg/Fe electrodes were integrated into this layer, the sensor displayed remarkable sensitivity toward humidity changes. This heightened sensitivity was linked to the formation of hydrogen bond networks between the water molecules and

the polysaccharides, which led to improved conductivity in humid environments. The sensor's compatibility with biological systems was verified through cytotoxicity tests that examined its interaction with human skin fibroblasts and human umbilical vein endothelial cells using the biocomposite film.

In a novel technique, experts harnessed the silk of spider egg sacs (SESS) to form an interference chamber inside a single-mode fiber (SMF). Variability in surrounding humidity led to shifts in the SESS diameter, which in turn modified the length of the interferometric cavity, resulting in a redshift in the spectral interference. This special quality made it possible to gauge humidity levels, with greater sensitivity emerging as the ambient humidity increased. Peak sensitivity reached 0.99 nm/%RH in the 90%–99% humidity range (Farahani et al., 2014). Within the arena of nanocomposite technology, investigators developed specialized composites consisting of zein, graphene oxide (Z-GO), Laponite, and carbon nanotubes (CNTs) using drop-casting methods. Created explicitly for detecting gliadin, a protein connected to autoimmune diseases, these composite structures showed a considerable improvement in detection performance compared to electrodes coated solely with pure zein (Martínez et al., 2017). Among the range of nanomaterials used, the composites that incorporated CNTs showed the strongest detection signals due to CNTs' innate ability to act as a binding agent for functional groups. These collective advantages led to superior sensor functionality, achieving an impressively low detection limit of as little as 0.5 ppm.

19.7 Conclusion

The advent of bioresorbable polymer-based sensors represents a groundbreaking shift in medical technology, specifically in the realms of minimally invasive procedures and personalized healthcare. Comprising naturally derived polymers like cellulose, chitosan, and alginates, as well as synthetic materials like polylactic acid (PLA) and polyglycolic acid (PGA), these sensors offer a multitude of clinical applications. They have particularly demonstrated their efficacy in orthopedics, where they can monitor stress and strain on implants and bones, and in cardiovascular care, where they assess parameters including blood flow, heart rate, and arterial conditions. The inherent capability of these materials to undergo bioresorption eliminates the need for additional surgical interventions to remove the sensors, thereby reducing medical costs and patient discomfort. Their biodegradable

nature not only alleviates the environmental burden but also contributes to a more cost-effective healthcare system. Ongoing research is geared toward fine-tuning the bioresorption rates and optimizing the longevity of these polymers, with the fields of miniaturization and materials science serving as catalysts for future advancements. In sum, bioresorbable polymer sensors are not merely a technological novelty but a substantive advancement that harmonizes with broader healthcare and environmental goals. They serve as a testament to the merging of medical innovation with ecological responsibility and patient-centric care. Their potential for further development and integration into mainstream medical practices holds promise for a future where medical monitoring is both efficient and less invasive.

Anionic ring opening polymerizations (ROPs), 65–66
Anterior cruciate ligament (ACL), 266
Antibacterial activity of halloysite nanotube (HNT)–polymer blends, 395–397, 399t
Antibacterial properties of halloysite nanotube (HNT), 395–397
Application(s)
  artificial skin, 268
  bioabsorbable polymers, 264–271
  bioresorbable tissue scaffold, 135–138
  bone tissue engineering, 270–271
  drug-delivery devices, 268–270
  implants for temporary fixation, 264–268
  ligament/tendon tissue engineering, 271
  neurosurgery, 266–267
  orthopedics, 264–266
  plastic surgery, 267–268
  tissue engineering, 270–271
Aqueous-soluble polymers, 154–155
Artificial bioabsorbable polymers, 261–262, 271
Artificial skin, application in, 268
Atomistic molecular dynamics simulations (aMDs), 174
Augmentation rhinoplasty, 267–268

Aureobasidium pullulans, 365
Azotobacter, 6–7

B

BAB block copolymers, 283–284
Bacillus
  B. cereus, 108–109
  B. pumilus, 108–109
Bacterial pigment prodigiosin (PG), 120
Baker and Lonsdale model, 235
Barium (Ba^{2+}), 151
Barrier membranes, 45
Basic fibroblast factor (bFGF), 261–262
Benzoic acid, 219–220
Best-fitting model, 242, 243t–247t
Beta-tricalcium phosphate (beta-TCP), 132–133
Bioabsorbable polymers, 259–260, 262–263, 265–266
  application, 264–271
    drug-delivery devices, 268–270
    implants for temporary fixation, 264–268
    tissue engineering, 270–271
  characteristics as implants, 262–263
    biocompatibility, 262
    degradability/absorbability, 263
    eliminable toxicity, 263
    sufficient mechanical strength, 262–263
  fixators, 264–265
Bioabsorbable sensors, 475–476
Bioabsorbable silicon, 475–476
Bioactive molecules, 366
Bio-based polymers, 63
Biocompatibility, 63, 71, 73, 109–110, 262, 386, 391, 443–444, 472–473
  of poly(lactic acid) (PLA) /poly(L-lactic acid) (PLLA) composites, 92
Biodegradability, 386–387, 443–444
  of poly(lactic acid) (PLA) /poly(L-lactic acid) (PLLA) composites, 92
Biodegradable polylactic-co-glycolic acid (PLGA) polymers, 299
Biodegradable polymers, 213–215, 386–387, 389, 443–445, 454–455
  application in drug delivery, 451–452
  classification for CDDS, 445–451
    albumin, 449
    alginate, 448–449
    chitosan, 447–448
    collagen, 446–447
    gelatin, 447
    phosphorus-based polymers, 450–451
    polyamides, 449–450
    polyesters, 450
    polyhydroxybutyrate, 449
  commercially available biodegradable polymer base products, 457
  materials, 85
Biodegradable sensing devices, 473–476
  blood glucose sensing, 475
  cardiac monitoring, 474–475
  intraocular pressure (IOP) measurement, 475–476
Biodegradable sensors, 476–477
Biodegradation process, 3–4, 443–444
Bioengineering, 24–28
Biofabrication, 101
Bio-fibers, 28–33
Bioglass 45S5, 294–295
Biological acceptability, 262
Biological adaptability, 262
Biological functionality, 67
Biological methods, 13
Biomaterials, 353, 386

Glutaraldehyde (GA), 157–159
Glycemic level monitoring, 473–476
Glycine amino acid, 484
Glycolic acid (GA), 325
Glycolipids, 368
Glycosaminoglycans (GAGs), 24–28
Gold nanoparticles (AuNPs), 373
Gompertz model, 238–239
Grafted chains on surface, 185
Grafting of bone, 76–77
Graphene oxide (GO), 71–72, 152–153, 159, 487
Graphite nanoplatelets (GNP), 51–52
Guided bone regeneration (GBR), 45

H

Halloysite nanotube (HNT), 385–386, 391–392, 408–409
  antibacterial activity, 395–397
  applications, 392
    biomedical, 413–414
  bioresorbable polymer-based, 393–394
  challenges and limitations, 412–413
  drug-delivery capacity, 397–400
  properties, 391–392
    reinforced polymer blends mechanical, 394–395
  wound dressings based on, 405–412
Healing compounds, 72–73
Healthcare surveillance, 481–482
Heart disease, 55
Heparin, 206–207
Heteroglycans, 367–368
Hexamethylene diisocyanate (HMDI), 336–337
1,6-Hexamethylene diisocyanate, 154–155
1,6-Hexane dibromide, 154–155
High aspect ratio, 391
High-energy irradiation crosslinking technique, 156–157
High-intensity, 156–157
High-modulus composite scaffold, 127
Higuchi's model, 229–231
Hixson and Crowell's cube root law, 231–232
Hopfenburg model, 236–237
Hot pressing method, 14
Human dental pulp stem cells (hDPSCs), 75
Human mesenchymal stem cells (hMSCs), 94–95
Hyaluronan bioresorbable composite, 57
Hyaluronic acid methacrylate (HAMA), 147–148
Hyaluronic acid-modified hydrogels, 34–36
Hybrid polymers, 390
Hybrid techniques, 134
Hydrazides, 8
Hydrochloric acid-activated halloysite nanotube (HNT-HCL), 412
Hydrogel(s), 147–148, 164, 338–339, 376, 475–476
  applications, 340t
  cross-linking, 148–157
  drying method, 159
  fabrication techniques, 157–165
    mold casting, 157–159
    nanoparticle-templated nanogel fabrication, 159–161
    physically and chemically cross-linked hydrogels, 158t
    prilling or laminar jet break-up, 159
    rheological toolbox, 164–165
    three-dimensional printing (3DP), 161–164
  networks, 147–148
  preparation methods, 339

chemical cross-linking, 341t
physical cross-linking, 342t
Hydrogen bonding (H-bonding), cross-linking by, 152–153
Hydrolysis, 386–387
Hydrophilic compounds, 343
Hydrophilic polymers, 471–472
Hydrophilic synthetic polymer, 371
Hydrophilicity, 328–329
Hydrophobic polymers, 471–472
Hydrophobicity/hydrophilicity, 328–329
Hydroxyapatite (HA), 55, 74–75, 112–113, 117, 133
Hydroxyapatite poly-L-lactide (HPLLA), 265
3-Hydroxybutyrate (3-HB), 119
3-Hydroxyhexanoate (3-HHx), 119
Hydroxyl (OH) groups, 152–155
Hydroxyl propyl methyl cellulose (HPMC), 216–217
3-Hydroxyvalerate (3-HV), 119
Hypoxia-inducible factor-1 (HIF-1), 360–361

I

Ibuprofen (IBP), 127
Illicium verum polymeric nanoparticles, 215
Immuno-fluorescence (IF), 408–409
Implantable medical devices, 74–77
Implantable sensors, 475
Implants, 389
application for temporary fixation, 264–268
In situ polymerization, 14–15
In vitro methods of bioresorbability evaluation, 12–13
biological methods, 13
physico-chemical methods, 12–13
In-vitro three-dimension (3D) cancer models, 207–208
Inductively coupled plasma mass spectrometry (ICP-MS), 485
Inductively coupled plasma optical emission spectrometry (ICP-OES), 485
Inferior vena cava (IVC), 136–137
Inflammation, 355, 357–358
Initiator, 65
Injection molding, 126–128, 387
Inorganic nanoparticles, 304
based composites, 304–312
Inorganic polymers, 390
Inorganic salts, 200–201
Integrated biomedical devices, 47
Integrated stretchable gold-doped graphene microneedles, 57
Interdigitated dressing electrodes, 41
Interleukin-6 (IL-6), 408–409
Intramolecular double rebridging (IDR), 172
Intraocular pressure (IOP) measurement, 475–476
Iodixanol, 54–55
Isopropyl groups, 187

K

Kappa carrageenan (KC), 367–368
Kef-based hybrid scaffolds, 94
Keratin, 370
Korea Advanced Institute of Science and Technology (KAIST), 208–209
Korsmeyer–Peppas model, 233–235

L

L-guluronate (G), 448–449
L-lactide/trimethylene carbonate copolymer (PLLA-TMC), 134
L-lysine-coated magnetite (Lys@Fe_3O_4), 70
Laboratory-scale tools, 204–204
Lactic acid (LA), 9, 325, 447–448
monomers, 87
Lactide, 86
Lactide-ethanol ester-1myr3-trimethylene carbonate (LA-GA-TMC), 260
Laminar jet break-up, 159
Laminate stacking process, 14–15
Laponite, 487
Large-amplitude oscillatory shear flow (LAOS), 164–165
Laser cutting technology, 43

Layering techniques, 480–481
Lead chloride, 219–220
Levonorgestrel (LNG) -loaded microspheres, 228
Ligament tissue engineering application, 271
Linear models, polynomial equation for, 239–240
Lipid nanoparticles, 373–374
Lipophilic planar matrix system, 229–230
Liquid photosensitive resin, 50
Lithography, 41–43, 126, 134
Lower critical solution temperature (LCST), 184, 187
Lyophilization, 333–336
Lysostaphin, 370–371

M

Macro-molecular modeling methodologies, 171
Magnesium (Mg), 137–138, 151, 483–484
  based polylactic acid bioresorbable membranes, 14
  iodine encapsulated with polyanhydride composites, 48
Magnetic nanoparticles (MNPs), 117, 304
Magnetic resonance imaging (MRI), 117–119
Magnetite nanoparticles, 117–119
Mannan-coated gelatin nanoparticles, 447
Manufacturing technology, 260–261
Mathematical models, need for and objectives of, 221
Matrix composition, 11
Matrix-derived factor-1 α (SDF-1 α), 261–262
Maxillofacial surgery, 263
Maximum safe concentration (MSC), 452–453
Mechanical properties of bioresorbable polymers, 387
Mechanical strength, 76–77
Medical applications, 87–88, 92, 107, 109, 116
  biodegradable sensing devices, 473–476
  bioresorbable polymer-based sensors
    fabrication techniques, 476–481
    pertinent physiochemical attributes for medical utilization, 470–473
  chemical sensors, 486–487
  physical sensors, 481–486
Medical devices, 55–56
  bioresorbable polymers, 330, 331t
Medical field, 23–24, 28
Medical interventions, performance of bioresorbable materials in, 33–37
Medical protective equipment, application of electrospun nanofiber membranes in, 205–209
Medical sector
  poly(lactic acid) (PLA)/poly-L-lactide (PLLA) composites applications, 92–98
  polycaprolactone (PCL)
    applications in different, 68–77
    based composites advantages, 67
    challenges and future of, 77
Medical technology, 471–472
Medical utilization, biodegradable polymers and pertinent physiochemical attributes for, 470–473
Medications, 360–361
  delivery, 472–473
Melt compounding, 91
Melt extrusion, 129
Melt processing methods, 91
Membranes, 200–201
Meshes developments, 98
Meso scale (MS) modeling method, 171, 186–187
Metal oxides, 137–138
Metallic nanoparticles, 373
Metallic stents, 95–96
Metals, 332, 363–364
  based NPs, 373
  nanoparticles, 373
Methacrylates, 8
Methacrylic acid, 371
Methotrexate (MTX), 229

Metropolis Monte Carlo (MC), 173
Michael addition, 155
Microcontact printing, 134
Microelectromechanical systems-based implants, 4–5
Microhardness (H) grades, 425
Micro-molding, 55–57
Microneedles (MNs), 55–56
Microparticles (MP), 284, 341–346
Microspheres, 444–445
Minimum effective concentration (MEC), 452–453
Minitab (software), 239
Model–dependent approach, 223–239
  Baker and Lonsdale model, 235
  Brazel and Peppas model, 235–236
  first-order model, 228–229
  Gompertz model, 238–239
  Higuchi's model, 229–231
  Hixson and Crowell's cube root law, 231–232
  Hopfenburg model, 236–237
  kinetic release models, 224t–227t
  Korsmeyer–Peppas model, 233–235
  Peppas–Sahlin model, 238
  Weibull model, 237–238
  zero-order model, 223–228
Model–independent approach, 241–242
Modified Higuchi's model, 235
Mold casting, 157–159
Molding process, 127–128
Molecular dynamics (MD), 171, 174–175
Molecular mechanics (MM), 171
Molecular modeling, 169
  polymers
    molecular simulation methods for designing polymers, 171–175
    polymer-based smart nanocarriers applications, 175–188
Molecular simulation for designing polymers methods, 171–175
  molecular dynamics, 174–175
  Monte Carlo (MC)
    computer software, 173
    simulation with, 172
Molecular weight, 11, 329–330
Molybdenum (Mo), 46
Molybdenum disulfide (MoS_2) bioresorbable sensor, 48
Monte Carlo (MC), 171
  computer software, 173
  moves, 172
  simulation with, 172
Mott theory, 433
Mucoadhesive drug release, 451
Multifunctional poly(lactic acid) (PLA) polymers, 101
Multifunctional polymeric nanocarriers, 177
Multiple scale simulations of sensitive polymers, 186–188
  polymers
    with pH response in simulations, 186–188
    with photo-response in simulations, 187–188
    with temperature response in simulations, 187
  simulations of responsive polymers, 188
Multivariate analysis of variance (MANOVA), 223, 242
Multivariate approach, 223
Multiwalled carbon nanotubes (MWCNTs), 114

N

N,N -ethylenebis (stearamide), 393–394
Nano-bioactive glass, 137–138
Nanocarriers, 450–451
Nanocomposites for wound healing, 372–377
  nonpolymeric nanoparticles, 372–374
  polymeric nanoparticles, 374–376
Nano-drug-delivery systems (NDDSs), 213
Nanofibers (NFs), 295, 376–377, 198–198, 198–198, 203–204, 206–207
Nano-glycosaminoglycan, 368
Nano-hydroxyapatite (n-HA), 94
Nanomaterials (NMs), 372
Nanomedicine, 444–445

Nanometer-sized hydrogels or nanogels, 159–161
Nano/microparticles, 57–58
Nanoparticles (NP), 67, 284, 341–346, 372, 449–450
  Ag-chitosan/polycaprolactone (PCL) composite, 71–72
  nanoparticle-templated nanogel fabrication, 159–161
Nanoprecipitation, 344
Nanostructured lipid carriers (NLCs), 373
Nanotechnology, 101
National Institutes of Health (NIH), 386
Natural bioabsorbable polymers, 214, 260–262, 271
Natural bioresorbable materials, 5–8
  alginates, 6–7
  cellulose, 7–8
  chitin and chitosan, 5–6
Natural fibers, 24–28
Natural polymeric nanoparticles, 375–376
Natural polymers, 24–28, 116, 268, 364–365, 389, 443
Natural substances, 363–364
Needle-free technology, 204–205
Negative temperature coefficient (NTC), 484–485
Neodymium ions, 436–439
Neoproteoglycans, 368
Neural stem cells (NSCs), 295
Neural tissue engineering, 14
Neurosurgery, application in, 266–267
Nonconventional techniques, 134
Non-Fickian type drug transport mechanisms, 234
Nonlinear regression models, 240–241
Nonpolymeric nanoparticles, 372–374. *See also* Polymeric nanoparticles
  ceramic nanoparticles, 374
  lipid nanoparticles, 373–374
  metal and metallic nanoparticles, 373
Nonsteroidal antiinflammatory drugs (NSAIDs), 361
Norfoxacin (NOR), 98
Novel bioabsorbable drug-eluting scaffold, 269–270
Nucleophilic addition reaction (nGTMH), 95
Nutrition, 362

O

Oil-in-water (O/W) emulsion, 149–150
One-pot process, 336–337
Ophthalmic pressure assessment, 473–476
Oral diseases, 75
Oregano essential oil (OEO), 72
Organic solvent, 477–478
Organism degradation, 10
Orthopedics
  application, 264–266
  implants, 96–97
    absorbable implant coating application, 269
Osmotic pumping release, 455
Oxygenation, 356–357

P

Particle leaching, 129–130
Particulate structures, 57–58
Peppas–Sahlin model, 238
Peptides, 368–371
Pertinent physiochemical attributes for medical utilization, 470–473
Phosphate buffer solution (PBS), 16–17, 482–483
Phosphate glass fibers (PGFs), 93, 421–422, 425–428
Phosphazenes, 450–451
Phosphoester, 450–451
Phosphorus-based polymers, 450–451
Photo-response in simulations, polymers with, 187–188
Photo-responsive polymers, 187–188
Photoinitiators, 155–156
Photolithography, 479–480
Photoluminescence spectra of $Al_xCa_{y-x}Nd_{01}P_{70}$, 435f
Photopolymerization, cross-linking by, 155–156
pH-responsive polymers, 186

Physical cross-linkers, 149–153. *See* Chemical cross-linking
cross-linking
charge interactions, 151
crystallization, 152
hydrogen bonding (H-bonding), 152–153
stereocomplexation, 149–151
Physical sensors, 481–486
Physically cross-linked hydrogels, 149
Physico-chemical methods, 12–13
Plastic surgery, application in, 267–268
Pluronic F127, 161–162
Poly(acrylamide) (PAM), 147–148
Polyacrylic acid (PAA), 147–148, 156–157, 186
Poly(α-esters), 63, 215
Polyamides, 449–450
Polyanhydride (PA), 46, 85, 215
Polycaprolactone (PCL), 10, 47, 54, 63, 74–75, 85, 115, 131–132, 138, 261–262, 267–268, 371, 375, 390, 395–397, 475–476, 481–482
advantages in medical sector, 67
biological functionality, 67
drug-delivery carrier, 67
mechanical properties, 67
based composites, 67
biopolymer composites, 63–64
challenges and future in medical sector, 77
development and synthesis of, 64–66
polycondensation, 64–65
ring-opening polymerization, 65–66
different medical sectors applications, 68–77
application fields of copolymers and, 68f
drug-delivery application, 71–72
implantable medical devices, 74–77
tissue engineering, 68–70
wound healing/dressing, 72–74
ibuprofen (IBP), 127
oregano oil/gelatin scaffolds, 72
PCL-sulfated chitosan, 53
polymers, 71
Polycondensation, 64–65
reaction for polycaprolactone (PCL) synthesis, 65f
Polydimethylsiloxane (PDMS), 395–397, 399t
Polydioxanone (PDS), 215
Poly(D-lactide) (PDLLA), 149–150, 269
Polydopamine (PDA), 54
Polyelectrolyte composite nanoparticles (PCNs), 261–262
Polyesters, 450
Poly(ester anhydride) polymeric nanoparticles, 215
Polyethylene (PE), 28–33, 173
Polyethylene glycol (PEG), 9, 71–73, 114, 134, 147–148, 156–157, 371, 395
Poly(ethylene glycol-*b*-caprolactone-*b*-ethylene glycol) (PECL), 155
Poly(ethylene glycol)diacrylate (PEGDA), 56
Poly(ethylene oxide) (PEO), 131–132, 338
Poly(ethyleneterephthalate) (PET), 88–90
Poly(glutamic acid)(PGA), 85
Poly(glycerol adipate), 450
Poly glycerol secabate (PGS), 47, 85, 482–483
Polyglycolic acid (PGA), 131–132, 215, 268, 277, 325, 385, 474–475
Polyglycolide. *See* Polyglycolic acid (PGA)
Poly(glycolide-co-ϵ-caprolactone) (PGCL), 68
Polyhydroxyalkanoates (PHAs), 107–112
Poly-3-hydroxybutyrate (P(3HB)), 134, 451–452
Poly(4-hydroxybutyrate) (P4HB), 268
Polyhydroxybutyrate (PHB), 108–114, 449
Poly(hydroxybutyrate-co-hydroxyvalerate) (PHBV), 115–120
based nanofibrous materials, 117
compounds, 119
PLA multifilament fibers, 119

Polyhydroxybutyrate-polyhydroxyvalerate (PHB-PHV), 47
Poly(3-hydroxybutyric acid-co-3-hydroxyvaleric acid), 115
Poly-3-hydroxybutyrate-co-poly-3-hydroxyvalerate (PHBV), 109
Poly[(hydroxymethyl glycolide)-co-(ecaprolactone)] (pHMGCL), 131–132
Poly(2-hydroxyethyl methacrylate) (PHEMA), 184–185, 408
Polylactic acid (PLA), 9, 24–28, 46–47, 55, 97–98, 131–132, 268, 325, 371, 385, 472–475, 482–483
  applications in medical sector, 92–98
    drug-delivery systems and orthopedic implants, 96–97
    scaffolds for tissue reengineering, 93–95
    stent development, 95–96
    surgical tools/meshes developments and dental materials, 98, 99t–100t
  based composites, 86f, 96–98
  based hybrid scaffolds, 94
  based polylactic-co-glycolic acid nanocomposites, 277
  bioactive glass-based composite scaffolds, 16
  biocompatibility and biodegradability, 92
  chemical structure and synthesis, 87
  fabrication methods, 90–91
    additive manufacturing, 90–91
    melt compounding, 91
    solvent-based methods, 91
  future perspectives, 101
  monomer, 277
  multifilament fibers, 119
  physical and thermal characteristics, 88–90
Poly(lactic-co-ϵ-caprolactone) (PLCL), 55, 68, 206–207
Polylactic–co–glycolic acid (PLGA), 46, 55, 97, 215, 268, 277, 328–329, 450, 485
  carbon nanotubes (CNT) scaffolds, 312
  copolymer, 279
  future prospects, 312–313
  hydroxyapatite (HA) composite, 133
  microparticles/nanoparticles (MP/NP), 284
  nanocomposite
    applications, 293–312
    carriers, 284–291, 290t
    composites applications with core–plasmonic nanoparticles, 304
    drug-delivery system, 299
    factors influencing degradation of, 291
    and implant preparation techniques, 285t–289t
    inorganic-NP-based composites applications, 304–312
    nano/magnetic nanocomposites applications, 304
    synthetic bone substitute and repair, 293–295
    therapy and theranostic agents, 299
    tissue engineering, 295–299
  nanocomposites, 277
  polymer solution, 43
  properties, 280–284
    copolymers, 280–284
    physiochemical and biological properties, 281t–282t
Poly(L-lactide), 149–150
Poly-L-lactide acid (PLLA), 85, 149–150, 265, 371, 481–482
  applications in medical sector, 92–98
  biocompatibility and biodegradability of, 92
  chemical structure and synthesis, 87
  fabrication methods, 90–91
    additive manufacturing, 90–91
    melt compounding, 91
    solvent-based methods, 91
  physical and thermal characteristics, 88–90
Poly(lactide-co-glycolide) (PLCG), 329–330
Poly(p-dioxanone) (PPDO), 52
Poly(-propylene carbonate) (PPC), 114, 336
Polymeric biomaterials, 109

Polymeric materials, 184–185
Polymeric nanoparticles (PNs), 215, 374–376. *See also* Nonpolymeric nanoparticles
  hydrogels, 376
  nanofibers (NFs), 376–377
  natural, 375–376

Prodigiosin (PG), 119
Profilometry, 13
Proliferation, 355
Properties of bioresorbable materials for biomedical application, 28–33
Proteins, 24–28, 368–371
  based polymers, 390
  glycosaminoglycan, 368
Proteoglycans, 368
Proton nuclear magnetic resonance (^{1}H NMR), 13
Pseudomonas, 6–7
  P. huttiensis, 108–109
  P. putida, 108–109

Q

Quadratic models, polynomial equation for, 239–240
Quantum ATK polymer simulator software, 175
Quantum mechanics (QM), 171
Quercetin (Q), 71–72

R

Radiopaque bioresorbable stents, 54–55
Reaction ion etching (RIE) process, 44–45
Reepithelialization, 355
Regenerated silk fibroin (RSF), 412
Regenerative medicine, 34–36
Regenerative silk (RS), 51–52
RegJoint insertiz (RJ), 265
Regression model analysis, 239–240
  polynomial equation for linear, first-order, and quadratic models, 239–240
Reinforcement material, 392
Relaxational mechanisms, 238
Release kinetic model, 222–242, 457
  model-dependent approach, 223–239
  model-independent approach, 241–242
  nonlinear regression models, 240–241
  regression model analysis, 239–240
  statistical approach, 222–223
Remodeling, 355–356
Resins, 180
Resorption process, 11–12
Responsive polymers, simulations of, 188
Rheological models, 88–90
Rheological toolbox, 164–165
Rifampicin, 449
Ring-like inculcated device, 75
Ring opening polymerization (ROP), 10, 63, 65–66, 86

S

Salt
  leaching, 129–130
  responsive polymers, 188
Salting out, 344
Scaffolds, 125–126, 138, 261–262, 332–338
  based strategies, 34–36
  fabrication, 138–139
    advantages and limitations, 334t–335t
  tissue reengineering, 93–95
Scanning electron microscopy (SEM), 13, 406–408, 410f
Scanning probe microscopy, 13
Segmented poly(ester-urethanes) (SPEU) -glass ceramic scaffolds, 52
Selective laser sintering (SLS), 49, 54, 90–91
Self-reinforced poly-L, D-lactide copolymer (SR-PLA 96), 96
Semisolid lipid nanoparticles (SLNs), 228
Sensitive polymers, multiple scale simulations of, 186–188
Sensors, 473–474
Sericin–silver nanoparticles (Ser-Ag), 408–409
Sex hormones in aged individuals, 358
Shape-memory polymers (SMPs), 97
Silicon nanomembrane, 47

WOODHEAD PUBLISHING SERIES IN BIOMATERIALS

Bioresorbable Polymers and their Composites provides a holistic view of these unique materials and their application in a range of biomedical applications. This book is evenly divided between fundamentals, processing methods and modeling approaches, and detailed coverage of a variety of applications, such as drug delivery, medical devices, and wound healing.

Key aspects including biocompatibility, biodegradability, and toxicology are also thoroughly covered, enabling the reader to be fully informed when fabricating and utilizing their selected bioresorbable polymer.

This book is an interdisciplinary and important reference for researchers in the fields of materials science, biomedical engineering, pharmaceutical science, and regenerative medicine, as well as R&D groups in the development of medical devices.

Key Features

- Introduces the reader to various processing and modeling techniques for bioresorbable polymers, including electrospinning, molecular, and finite element modeling.
- Covers a range of key bioresorbable composites, such as PCL, PLA/PLLA, and PHA/PHB/PHBV.
- Explores a wide selection of biomedical applications of bioresorbable polymers, from tissue engineering and stents to biosensors and medical devices/implants.

About the Editors

Deepak Verma, Research Assistant, Nano-science and Technology, Graduate School, Chulalongkorn University, Bangkok, Thailand. He also served as an Assistant Professor, Department of Mechanical Engineering, Graphic Era Hill University, Dehradun, India.

Manunya Okhawilai, Researcher, Metallurgy and Materials Science Research Institute (MMRI), Chulalongkorn University, Bangkok, Thailand.

Kheng Lim Goh, Director of Research and Associate Professor (Reader) in Materials Technology, Newcastle University, Singapore.

Seeram Ramakrishna, FREng, Everest Chair is a Professor of Materials Engineering at the National University of Singapore (NUS), Singapore.

Pooria Pasbakhsh, Adjunct Associate Professor at the School of Engineering, Monash University, Malaysia.

Mohit Sharma, Principal Scientist at the Institute of Materials Research and Engineering (IMRE), Agency for Science, Technology and Research (A*STAR), Singapore.

Silkworm Biotechnology

Priyanka and Poonam Kumari Yadav

Abstract

Silkworms have been used for generations to meet human requirements. The silk produced by the silkworm has a high economic value. Genetic engineering may result in improved silkworm species that produce more silk and are more resistant to illnesses and environmental variations. The silkworm is also a useful model for studying the molecular basis of development and gene expression utilising molecular biology methods.

Keywords: Biology genetic engineering, silkworm

Introduction

Today's biotechnology-based industry faces a bottleneck towards further advancement owing to the lack of proper gene expression systems. Despite the tremendous advancement of bioscience, there are still many proteins whose structures remain unknown. Scientists working in the field of life science needed a technique that could rapidly express protein in huge quantities and purify protein in a biologically active form. Thus said, with the completion of Human Genome Project, we have come across a herculean task of trying to understand the function of the proteins being coded by the genes. Many researchers proved silkworm biotechnology is one of solutions. Furthermore, recent reports showed that the recombinant baculovirus containing mammalian cell-active promoter can exhibit efficient gene transfer of potential vaccines into mammalian cells. This would be a great breakthrough in production of recombinant eukaryotic proteins and viruses, which will be a powerful tool in a new proteome It is a lepidopteran insect. The rearing of silkworm for production of silk is called as sericulture. Silk is secreted by silk gland of the silk worm and it is a fibrous protein of insect origin. Silk is known as the queen of textiles and BIOSTEEL because of its strength. Silk fiber consists of two types protein namely fibroin (75%) and sericin (25%). China ranks first in the production of silk. India is the second largest producer of silk after china. It is also the largest consumer of silk in

Chapter - 1

Salinity Tolerance Mechanism and Responses of Plants

Hidayah Faisal H. and Adajani Alotaibi

Abstract

Salt stress is a significant issue that impacts agriculture worldwide. Salinity negatively affects several physiological processes, and causes alterations on growth, development, and reproduction. To cope with such stressful conditions, plants have developed effective strategies to response to stressful conditions in fast and efficient manne. This chapter reviews our current understanding of salt stress impacts on plants. Recent research on salt mechanisms to tolerate a high salt level, including hormone regulation and metabolism modifications, has been summarized. The involvement of transcriptional and post-transcriptional gene regulation in plants' responses toward salinity has been briefly discussed. This knowledge will improve our understanding of salt stress in plants and how plants respond and alter their expression to develop salt-tolerant plants using bioengineering approaches. Finally, we highlighted some aspects that should be clarified in future research to understand salt tolerance well.

Keywords: salt stress, transcription factor, DREB2A, salt tolerance, epigenetic modification, hormone, DNA methylation, histone modification, metabolic modification, hormone regulation

Introduction

XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX

1. Salinity: A Global and Cellular stress factor

The agricultural world faces serious challenges to enhance food production by 70 percent by 2050 to meet the global rising population's demands [1]. However, expanding the stress factor in the environment limits the growth of agricultural areas. According to the Food and Agriculture Organization of the United Nations, 800 million hectares are under hyperosmotic stress, representing 7 percent of the land, 20 percent of arable land, and 40 percent of the total irrigated land [1]. As a consequence of poor irrigation or other typical causes of soil salinity, such as fertilizer use [2].

Chapter - 1

microRNA and its Regulation

Pooja SK and Thota Joseph Raju

Abstract

Post-transcriptional gene expression is regulated by 18-22-nucleotide microRNAs (miRs, MiRNAs). MiRNAs regulate gene expression by interacting with the 3′- and occasionally 5′-ends of target gene mRNA. MiRs influence up to 60% of plant/animal protein-coding genes. miRNA regulate most biological processes. MiRNA misexpression changes cellular function, differentiation, apoptosis, and survival signalling, linking miRNA to disease pathophysiology. MiRNAs must be properly managed. Multiple processes in miRNA processing influence miRNA levels. MiRNA is regulated at various levels, including transcriptional (promoter methylation and transcription factors) and post-transcriptional (Drosha and Dicer in the nucleus and cytoplasm). RNA methylation, uridylation, adenylation, and editing affect miRNA stability. Also oestrogen and hypoxia effects. Human malignancies affect miRNA expression by abnormal DNA methylation. DNA hypomethylation upregulates onco-miRs and downregulates tumor-suppressor miRNAs. DNA hypermethylation downregulated tumour suppressor miR-132, which binds to paxillin's 3′-UTR posttranscriptionally in colorectal cancer cells. After 5-Aza-CdR therapy, miR was dramatically upregulated, suggesting that DNA hypermethylation downregulates miR-132 in CRC. Thus, cancer gene therapy now uses DNA methyltransferase inhibitors to restore miR-132 expression. CRC targeted therapy may use miR-132 methylation. Lin28 suppressed tumor-suppressing miR Let-7. Lin28 inhibited pre-miRNA processing via a conserved sequence with the terminal loop region. Lin28 recruits the terminal uridyl transferase TUT4 complex to cytoplasmically uridylate pre-let-7 to inhibit let-7. Uridylation hinders Dicer processing and degrades pre-let-7. Further characterization of regulatory elements of miRNA biosynthesis and function will shed light on the complex gene regulatory network governed by miRNA in various pathological mechanisms and the mutual regulation of DNA methylation and miRNA, providing a molecular basis and biomarkers for therapeutic strategies.

Chapter - 4

Biotechnology Based Green Energy: A Solution towards Sustainable Development

Kailash Chandra and Harshada Joshi

Abstract

The energy resulting from nonrenewable resources such as natural gas, crude oil and coal, has encouraged technological progress and maintained advances in a wide variety of productive sectors. The demand for crude oil and natural gas has increased in the past years, which is responsible for global warming, the production of smog and water pollution. Therefore, high reliance on fossil fuels is observed. This overview can have risk from an energy security point of view owing to the continuous fluctuation in crude oil prices. In this sense, to develop a sustainable economy in the near future there will be a need of research on alternative energy sources. The use of renewable energy, its production and research have added importance in transportation, building and, industrial sectors, in response to grasp sustainable development.

Biotechnology plays a crucial role in biofuel production. It helps in decreasing agronomic inputs, optimizing process characteristics and engineering the plants to produce high yield and hence high energy. It helps in decreasing agronomic inputs, optimizing process characteristics and engineering the plants to produce high yield and hence high energy. Improvements in the synthesis of biofuels could be expected, as progress takes place in the field of biotechnology. The chapter comprises of various sources of green energy and role of biotechnology in exploring the alternative method for production of biofuels.

Keywords: Green energy, biofuel, biodiesel, biogas, bioethanol

1. Introduction

Energy does have an important role in modern life. Demand for energy is increasing exponentially day by day due to the exponential growth of the world population. The world has presently twin crises of fossil fuel depletion and environmental degradation. These problems can be overcome by green

Multifunctional Hypoxia Imaging Nanoparticles

Preeti Sharma, Pooja Kumari, Tikam Chand Dakal, Jyotsana Singh, and Narendra Kumar Sharma

Abstract Hypoxia is a condition in which there is a scarcity of oxygen. It is mainly associated with diseased circumstances, although it can also be a trait of healthy physiology. It is a pathophysiological condition linked to numerous ailments such as hyperglycemia and hypoglycemia inflammation, wounds, tumors, and so on. These conditions are all among the most detrimental to human health. Presently Rapid acknowledgment of this condition becomes essential. In the course of the evolution of clinical and preclinical investigation for the diagnosis of multiple diseases, molecular imaging has become a potent technique. A promising way to solve this drawback is the development of multifunctional hypoxia imaging nanoparticles that enhance the efficiency, specificity, and sensitivity of molecular imaging by providing molecular and functional information in an invasive manner under in vivo conditions. The most significant feature of Nanoparticles throughout the hypoxia imaging procedure is their higher penetration and retention implication with lengthy circulation capacity and easy encapsulation capability, generating them the most influential target for utilization in the biomedical application as a hypoxia imaging technique. Here, we concentrate on a recently generated nanoparticle that has been adopted as a tissue-level molecular imaging probe for numerous diseases.

1 Introduction

Oxygen is a key determinant of standard aerobic metabolism in mammals. When cells suffer from lower-than-usual oxygen levels and pressure, it is called a hypoxic condition. Hypoxia is caused by poor oxygen transport, low blood oxygen levels, and decreased cellular oxygen uptake (Eltzschig and Carmeliet 2011).

Mammals have their mechanism of adaptation to hypoxia by increasing respiration, blood flow, and survival response. If in any situation oxygenation is disrupted, this adaptive mechanism assists them in restoring oxygenation and helping the body adapt to hypoxia. This cellular modification mechanism is dependent on the transcription factor HIF, which is active when there is a lack of oxygen and is dormant when oxygen is present. HIF (hypoxia-inducible factor) controls other immune responses in inflammatory bowel disease, certain cancers, and infections (Lee et al. 2019). Various studies show that hypoxia signals control human organ systems such as the lungs, liver, kidneys, and heart. So we can use this hypoxic state as a therapeutic board and also as a biomarker for imaging certain health problems. Recent studies show that hypoxia emerges as a hallmark for the early detection of tumors. This interdisciplinary research should focus on the development of nanomaterials that can be used for effective and non-invasive early detection of cancer (Lledos et al. 2018). In the case of a cancer study, the hypoxia-responsive nanoparticles act vigorously in the existence of a hypoxic tumor microenvironment. The various researchers' results suggest that its activity improves the effectiveness of radiotherapy, chemotherapy, and

other imaging and therapeutic strategies. Hypoxia is associated with many infections such as cancer, neurological disorders, and kidney disease. Numerous researches have been conducted to illustrate the benefit of hypoxia-activated nanoparticles and pro-drugs in tumor-directed cure. Hypoxia-responsive nanoparticles are dormant throughout perfusion and under standard physiological circumstances but become activated during hypoxia when they enter the hypoxic tumor microenvironment (Wang et al. 2021). Overcoming hypoxia is therefore a significant strategy used for the cure of dense tumors. For that purpose, researchers have attempted to enhance useful chemicals and nanoparticles that could be utilized for scanning and indulge hypoxic tumors noninvasively and efficiently. The aim is to retreat hypoxia by creating oxygen and activating nanomolecules/medicines into the hypoxic tumor microenvironment, as well as targeting tumor hypoxia biomarkers to enhance treatment efficacy.

In addition, so many studies are being conducted for non-invasive imaging using nanomaterial. In recent years, these suggesting approaches get more attention in which the formation of the multifunctional platform occurs including lanthano crystals, iron oxide, polymers, and gold. These are the active Nanoprobes that can respond to the nearby environment and serve as biomarkers to enhance the effectiveness, specificity, and sensitivity of molecular imagining. During this imaging, the physiological limits that come under will be redox state, presence of enzyme, pH, and hypoxia that can be designed as stimuli for the activated probes (Liu et al. 2019). At the moment, all researchers are looking for non-invasive imaging approaches. Non-invasive hypoxia imaging technologies that are commonly used include calculated tomography and positron emission tomography, MRI, photoacoustic imaging, and optical imaging. Optical hypoxia imaging is the most economical, sensitive, and high-output imaging technology in all of them. This is due to the design of the probe, which is mostly composed of a metal complex and organic dye. The metal complex has several properties, including high oxygen sensitivity, a lengthy phosphorescent for a lifetime, and the ability to penetrate within the cell membranes. It is applied in cell culture and it can also add to animal tissue samples of tumors. To improve the precision and stop the blocking of tissue, researchers develop a ratiometric hypoxia sensor that uses the hypoxia-insensitive dye with a hypoxia sensor and uses its percentage for describing the absorption of oxygen (Ma and Xia 2021).

Meanwhile, other investigators are concentrating on organelle structural hypoxia conditions like the distribution of mitochondrial hypoxia. It is essentially a sensor-based system in which the hypoxia sensor accomplished mitochondrial targeting, allowing us to detect the concentration of oxygen inside the cell. These probes and sensors could also be used in preclinical cancer diagnostics. Here, Fig. 1 depicted the basic design of nanoparticles with their vast applications.

To accommodate all scanning modalities through optical hypoxia imaging, the technologies require a transporter onto which entirely agents are inserted. The nanoparticle technique would be extremely suggested for this particular reason. Nanomaterials have unique properties that make them suitable for this purpose, such as lengthy circulation and facile endocytosis. These characteristics aid the hypoxic imaging sensor in reaching a specific location. Furthermore, the diverse basic designs of nanomaterials allocate each modality and purpose to act collectively (Das et al.

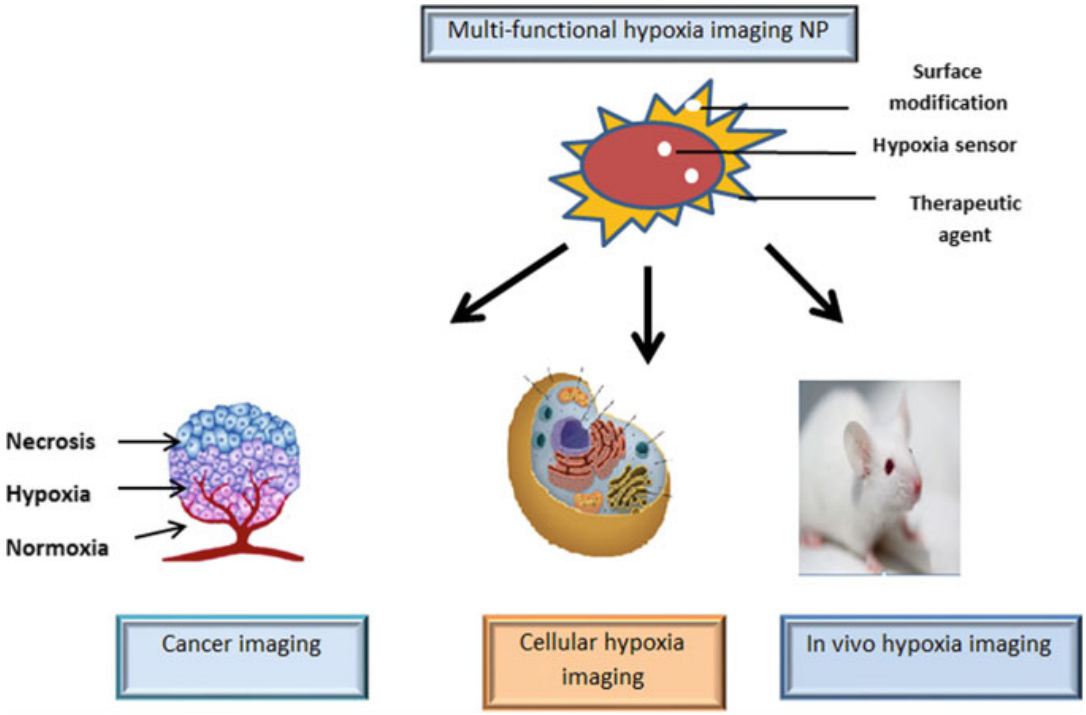

Fig. 1 Applications of multifunctional hypoxia imaging nanoparticles

2020). In this case, the nanoparticle can also apply active aiming and immune leak functional group by the surface alteration. Meanwhile numerous confront and drawbacks remain in the application of multifunctional hypoxia imaging nanomaterials. Here, we are focusing on recent advancements and various kinds of multifunctional hypoxia imaging nanoparticles.

2 Types of Nanoparticles

The complex architectures of multifunctional hypoxia imaging nanoparticles vary. Nanoparticles are characterized according to their structure as self-assembled nanoparticles, core–shell structure nanoparticles, micelle-liposome-like nanoparticles, and matrix dispersion nanoparticles.

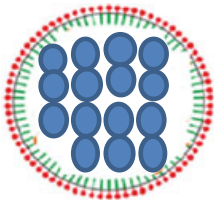
2.1 Self-assembled Nanoparticles

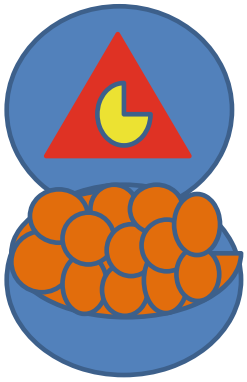
The inner core–shell of these particles is inherently hydrophobic, making bioavailability much better than any other nanoparticle. Some researchers fabricate such particles using porphyrin Pt (II) and polyfluorene-based hyperbranched complexed polyelectrolytes. Substances that adhere to these particles are with a size of about

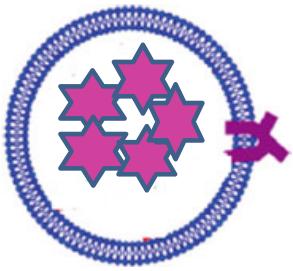
10 nm. They do not have much greater encapsulation or loading capacity compared to nanocarriers. Hydrophobicity and polarity play key roles in drug development and as a hypoxia sensor. These particles exhibit van der Walls binding between molecules, giving them a relatively loose structure. Some other related data also show that strength can be increased through crosslinking activity. This makes it much stronger (Park et al 2015; Shi et al. 2014; Zhou et al. 2015).

2.2 Core–Shell Nanoparticles

As the name suggests, these nanoparticles have a center and a shell. In most cases, the principal is formulated as a hydrophobic treatment and metal compound. Some nanoparticles are also formulated in the core part. They are hydrophilic in nature, making them inherently water soluble and biocompatible. It consists of biomaterials such as hyaluronic acid and many others. In one study, it was found that a researcher formed an up-conversion nanoparticle core (UCNP), the core of which interacts with hypoxia sensors in the shell. This modification ability of nanoparticles allows them to target hypoxia imaging therapy (Li et al. 2018a, b, c; Wang et al. 2016; Xu et al. 2016).







2.3 Micelle-Liposome-Like Nanoparticle

Micelles and liposomes work together to form an emulsion and deliver a drug. This is one of the best nanocarriers used in optical hypoxia sensors and drug delivery. Micelles have a monolayer and liposomes have bilayers. The lipophilic agent is layered in a single phase and the hydrophilic water phase can be loaded into the bilayer liposome. According to several types of research, it has been found that the cancer cell membrane shows binding with metal ions and they further show immune evasion ability for tumor targeting. A researcher attaches a cancer cell membrane to an organometallic porphyrin scaffold that exhibits a distinctive tumor-targeting feature. Apart from this, membrane-targeting phospholipid and amphiphilic polymers can also be used in the manufacture of these particles. There show biocompatibility and much better results than other nanoparticles (Feng et al. 2017a, b; Huang et al. 2018; Luo et al. 2016; Yu et al. 2017).

2.4 Matrix-Dispersed Nanoparticles

The matrix area of these particles consists exclusively of polymer. Wherein the sensors of hypoxia and the imaging agent are evenly distributed. These nanoparticles and sensors would be small by nature. A researcher fabricated polymer-based

Table 1 The general disruption of the general dispersed nanoparticles is summarized in the form of a table

Nanoparticles	Structure	Diagrammatic view	References
Self-assembled nanoparticles	Have a relatively loose structure		Zhou et al. (2015), Park et al. (2015), Shi et al. (2014)
Core–shell nanoparticles	High loading capacity		Xu et al. (2016), Wang et al. (2016), Li et al. (2018a, b, c)
Matrix-dispersed nanoparticles	Small molecules distributed evenly		Luo et al. (2016), Huang et al. (2018), Yu et al. (2017), Feng et al. (2017a, b)
Micelle-liposome-like nanoparticle	Better Biocompatibility		Li et al. (2018a, b, c), Qian et al. (2016), Liu et al. (2017), Liu et al. (2014), Papkovsky (2013)

supramolecular nanoparticles used for ratiometric hypoxia imaging. In some places, small nanoparticles can be encapsulated with a matrix to grow larger. These small particles are metal clusters, dots of quantum, and UCNP, which can serve as the fluorescent functional causes. These particles protect themselves by self-extinction (Li et al. 2018a, b, c; Liu et al. 2014, 2017; Papkovsky 2013; Qian et al. 2016). The general disruption of these particles is summarized in form of a table (Table 1).

3 Hypoxia Imaging Tumor-Directed Nanoparticles

Several multifunctional image-guided nanoparticles for the Therapy of cancer were evolved to construct a theranostic platform for the treatment of cancer. Hypoxia plays a debilitating role in cancer for physicians and patients. This state rendered the solid tumor resilient to radiotherapy and chemotherapy. Cancer cell mutations and

tumor metastasis can be caused by hypoxia. Hypoxia imaging can help localize the tumor area. Various techniques have been created by researchers to further exploit optical imaging of hypoxia to guide cancer therapy and observe therapeutic efficacy (Weissleder 2001).

3.1 Hypoxia Imaging by Phosphorescent Hypoxia Probe

In this procedure, phosphorescent hypoxia probes produce ROS that eliminates cancer cells. ROS can be generated by an agent known as a photosensitizer. This technique is also known as the PDT technique and shows a better therapeutic effect than chemotherapy. It has been widely recognized that chemotherapy can also produce some side effects such as drug resistance, and toxicity at the cellular and organ levels. Compared to PDT, it is a non-invasive method that is highly accurate. It is an image-directed therapy method. In this process, triplet O_2 particles respond through photosensitizer and thereafter convert to singlet form. These singlet species and reactive oxygen species are used to cure tumor cells. When the light source is applied to cancer cells, due to radiation, the photosensitizer switches oxygen into single free radical oxygen that helps kill cancer cells. Here, oxygen detection is built on the linear relationship between oxygen concentration and phosphorescence intensity. The three main factors that fall under this are oxygen, phosphorescence, and light. Hypoxia-based tumor microenvironment leads to tumor PDT resistance. This method shows high effectiveness for the diagnosis of early-stage tumor cells and also killed the cell by light irradiation. These in situ hypoxia images guide PDT techniques and results can be analyzed by confocal microscopy and MTT assay. Some more complicated ones also employ phosphorescent metals such as ruthenium, platinum, porphyrins, and iridium. This complex is used to detect the image and o_2 levels in existing organisms and hence can work as a real-time monitor for o_2 levels (Lv et al. 2018; Zhao et al. 2015; Zhou et al. 2015).

Ruthenium

HIF inhibition was utilized specifically to treat hypoxia-related illness in this manner. Some researchers created a hypoxia imaging agent based on ruthenium (II) anthraquinone complexes and HIF-1 alpha suppression. This particle shows a 40-fold change in phosphorescence intensity from 20 to 1% oxygen content, so we can say that this Ru has excellent intracellular hypoxia imaging ability. It presents effective liquid solubility and a potent phosphorescence emission in hypoxia. The binding capacity of ruthenium makes it favorable to use as a complex for particle formation. One researcher designed a UCNP mesoporous silica shell structure nanomolecules with an O_2 indicator for ruthenium dichloride. This form is used as a quenchable indicator to sense oxygen. Since the oxygen concentration can be reproduced through the luminescence at 613 nm and the excitation at 980 nm, by using this, we can do a deep tissue study (Lv et al. 2015).

Platinum (II) and porphyrin

Scientists have created Pt (II) porphyrin with luminous properties of photo physical like high photostability, and large stoke shift. It shows brilliant radiometric luminescence reaction to the o_2 level with great consistency and full reversibility. It was also observed in other studies for the identification of early phase and therapy system porphyrin illustrate a high PDT efficacy and extended lifetime and a high signal-to-noise ratio in fluorescence recognition (Lv et al. 2016).

Iridium (III) complex

This complex is reduced by intracellular oxygen which is repaired during a two-electron reduction in a hypoxic environment. A group of scientists designed an oxygen-sensing complex and covalently attach this to iridium to monitor oxygen concentration. One more scientist designed two iridium complexes that specially mark mitochondria and lysosomes in existing cells. These mitochondria are further targeted for the improvement of the PDT effect. This type of experiment and their data demonstrate that such alteration of complexes allows better imaging for hypoxia (Feng et al. 2017a, b).

4 Hypoxia Active Nanoparticles for Chemotherapy

Quinones

Pro-drugs are made up of quinones which could be employed as hypoxia-responsive nanoparticles. The structure of quinone could be triggered through the presence of a hypoxic situation in the cells of a tumor where it produces semiquinones radicals or some other two electron-reducing enzymes such as hydroquinones and DT diaphoresis (Zhu et al. 2012).

The class of natural compounds having quinone as their core structure becomes a highly active class for biologically active agents such as vitamin K, doxorubicin (anticancer compound), and coenzyme Q. In this quinone, some more compounds also included such as MMC (mitomycin C), porfiromycin, EO9, and AZQ. The MMC was isolated from Streptomyces caespitosus. This compound showed high solubility, and it was the first used quinone-based medication documented as bioreductive hypoxia selective alkylating agent. After the uptake of cellular or intracellular, it is distributed within the nuclei. Through a reductive metabolism, the MMC and its analogs show their cytotoxic effect. It binds with the DNA through great competence and specificity at the sequence CpG while MMC is related to acute or chronic toxicities. One researcher developed an MMC-soybean- phosphatidylcholine nanoparticle. That enhances the chemical activity of MMC NP in a hypoxia environment. One more nanoparticle was developed by the same researcher with improved characteristics that show lesser size dispersal and high zeta potential with improved stability (Caramés Masana and Reijke 2017; Erdogar et al. 2014). One

more nanoparticle was designed by researchers in which the first two-photon fluorescent probe combining luminescent ruthenium (II) complex by a redox-active form of anthraquinone moiety was further used for the in vivo imaging of hypoxia with high-resolution spatial imaging (Pierce et al. 2010).

Nitroimidazoles

It is a double responsive Nanotransporter that comes as the principal method which is used to enhance the traditional efficacy of PDT ability. This composition is made up of two components one is a 2 nitroimidazole grafting conjugated polymer and the other one is doxorubicin. This Nanocarrier complex generates reactive oxygen species after a light-triggered stimulus to release a hypoxia stimulus. This complete process starts with irradiation of light, and it generates ROS that successively induces hypoxia at the tumor site by converting 2- nitroimidazole into 2 amino imidazoles. This series of reactions occurs by the release of single electron reduction catalysis through a series of nitrocellulose reductase with bio-reducing agents like NADPH that disassembles the drug transporter. This doxorubicin induces cytotoxicity via the damaging of DNA. This strategy gives an innovative pattern for the drug release system (Hou et al. 2009, 2013).

Aliphatic N oxide

The AQ4N drug shows a Bis N oxide Quinone structure that experiences bioreduction in the hypoxic cell. This drug has been undergoing phase I and II clinical trials. In this process, the reduction by hem proteins including cytochrome (P 450) and nitric oxide synthase (NOS) occurs, and the final product AQ4 form. This reduction product AQ4 shows high DNA affinity by targeting topoisomerase II and this topoisomerase II stops the hypoxic cell to reenter the cell cycle. The AQ4N drug considers an ideal bioreductive drug that can enter intensely into the tumor and it shows very less tissue toxicity. Scientists designed hypoxia probe 1(HyP-1) a hypoxia-responsive agent that is used for photoacoustic imaging. In vitro, it can be used as a hypoxic activator, and in cultured cells or multiple diseases model, it is used in vivo. It is used for three-dimensional visualization of intertumoral hypoxia with the best resolution (McCarthy et al. 2003; Qian et al 2016; Zhang et al. 2015). The comparative studies of before and after administration of Hyp1 were done for understanding the clear role of these particles during hypoxia imaging. Knox et al. establish a hind limb ischemia model to understand the response of Hyp1 in a hypoxic environment during in vivo conditions. Additionally, regarding the use of AQ4N in diagnosis, Feng et al. designed an AQ4N liposome-based nanodrug that relies on a commercial hydrophilic particle as a hypoxia-activated prodrug by a modified hydrophobic Ce6 as a photosensitizer which shows encapsulation with PEGylated liposomes. This liposome can use a probe for positron emission tomography (PET) after chelation with a Cu isotope. That can be used in in vivo imaging of PET, PDT, and hypoxia-dependent cytotoxicity. Based on these results, Feng et al. composed AQ4N through glucose oxidase to obtain a hypoxia-activated therapy. In this process, the glucose oxidase stops the supply of glucose to the tumor and exhausts the tumor's oxygen to produce a hypoxic enrichment. Additional treatment with AQ4N loaded with

liposome enhanced activation of hypoxia and strong synergistic antitumor properties (Feng 2017a, b; Knox et al. 2017; Mehibel et al. 2009; Nishida et al. 2008; Paoni et al. 2002).

5 Conclusion and Future Scope

Even though nanotechnology has been studied for ages, while their therapeutic application has yet to be proven. The cause of this can be related to two parts: the tumor part and the nanomaterial part, with tumor heterogeneity being one of the most important. Tumor heterogeneity is defined by diverse genetic alterations and phenotypic appearance profiles at the genetic level, and by complex cells inside the tumor-like fibroblasts, other stromal cells, and inflammatory cells at the cellular level. Although the hypoxia-active nanoparticles play an important strategy to overcome tumor heterogeneity, they can also be employed to develop analytic and medicinal approaches for a wide range of tumor cells. And the nanomolecule has various disadvantages, including limited tumor retention due to its enormous size and rapid renal clearance due to its comparatively small size. Due to their positive charge, the nanoparticles have a short perfusion time, which allows them to easily pass through membranes. Scientists have created a nanoparticle with zero potential during its perfusion period that can become positively charged after being activated by a hypoxic microenvironment.

Here, we summarize recent advances in improving radiation efficiency by focusing on hypoxia. Built on the relationship between hypoxia and radiation resistance, numerous new substances have been developed for the treatment of hypoxic tumors.

Radioactively labeled NP is suitable for further research in this direction due to their consistent half-life and efficacy.

When compared to minor molecular imaging probes, nanoprobes are reflected as a suggesting stage for designing responsive mechanisms to various stimuli such as hypoxia, acidic conditions, various enzyme redox status, and so on, because their well-built particular area provides a large room to alter their functional moieties. Despite numerous accomplishments in this field, significant obstacles remain in the construction of activated nanoprobes for in vivo imaging.

Hypoxia is increasingly recognized as a significant factor in the pathophysiology of additional important causes of death, such as myocardial ischemia, metabolic disorders, reproductive disease, and cardiac disease. For this reason, more imaging-related nanoprobes must be created, as they will provide a wide field for imaging different diseases at the molecular level.

1 Introduction

Cardiovascular disease is the leading cause of death in the world. According to the data, cardiovascular disease is responsible for an estimated 17 million deaths (30% of all deaths) each year around the world. Cardiac rehabilitation is an important factor in the prevention of cardiovascular disease and can help to minimize age-related cardiovascular mortality, which is a national health priority [1]. Cardiovascular rehabilitation recommends exercise, cardiac risk factors, therapy, and modification in educating people, according to the medical assessment. These services are explicitly designed to minimize the risk of premature death by limiting the physical and physiological effects of cardiac disease [2]. The overall principle is the identification of the patient first, then enrollment in cardiac rehabilitation programs. The ideas of family medicine are aligned with the modern concept of medical home, which includes complete risk factor reduction and longitudinal treatment [1].

Cardiovascular rehabilitation is a program that focuses on physical activity. It is a patient-specific program aimed at enhancing the patient's physical, behavioral, social, and occupational conditions. Via physical activity and educational techniques, cardiovascular rehabilitation services foster a number of advantages [3,4]. Although, the increased metabolic demand required for physical activity causes a number of adaptations in the

Cardiovascular Toxicity and Therapeutic Modalities Targeting Cardio-oncology

cardiopulmonary and autonomic systems, which can be linked to the appearance of signs and symptoms. Cardiovascular rehabilitation comprises a multidisciplinary intercede, which includes psychological counseling, smoking cessation, patient education, exercise training risk factor control, and vocational reintegration [4].

2 Cardiopulmonary stress testing in prehabilitation, habilitation, and rehabilitation

Cardiopulmonary stress testing is a way to measure how well a person's heart and lungs are working during exercise. The measurements are made of the amount of oxygen taken by the body while riding a bicycle or walking on a treadmill. Cardiopulmonary exercise testing (CPET), also known as cardiopulmonary stress testing, has emerged as a valuable clinical method for evaluating exercise ability and projecting outcomes in patients with cardiac arrest and other cardiac issues. It demonstrates the importance of the integrative exercise response involving the pulmonary, cardiovascular, hematopoietic, neuropsychological, and skeletal muscle systems, which is not adequately expressed by individual organ system function measurements [5]. During a symptom-limited exercise test, CPET includes assessing respiratory oxygen absorption (VO_2), carbon dioxide emission (VCO_2), and ventilator steps.

3 Cardiopulmonary exercise testing

Several methods for calculating ventilation and respiratory gas parameters during exercise still exist in cardiopulmonary exercise testing. Breath-to-breath analysis methods are used in the most advanced clinical systems because they provide the most accurate indicator of metabolic response to exercise. A nonrebreathing valve is attached to a mouthpiece in the cardiopulmonary exercise testing system to avoid the mixing of inspired and expired air. A metabolic cart specifically designed for practical testing is normally built-in cart in the cardiopulmonary exercise testing machine for this oxygen, and carbon dioxide gas analyzers are usually built-in cart. The air flow signals are integrated over the time of inspiration and expiration to calculate respiratory volumes. The average minute volumes can be determined by multiplying the breath-to-breath data by the respiratory rate [6].

4 CPET protocol

Many different procedures are used for cardiopulmonary exercise testing. In addition, the procedure chosen is determined by the test's intent

TABLE 1 Comparative exercise equipment [5].

Variable	Cycle	Treadmill
(PVO_2) level	Low	High
Blood gas connection	Easier	More difficult
Noise	Comparatively less	Moderately high
In hand on safety	Safe	Moderately less safe
Load bearing in large subject	A lesser amount	Moderately high
Scale of leg strength exercise	A smaller amount	More
Suitable for	Patients	Energetic common subject

and the patient's functional ability. Both bicycle and treadmill procedures have been used in the treatment of patients with cardiopulmonary issues. Ergometry treadmill fitness testing has many benefits over cycling (Table 1), and for the majority of people, treadmill walking is a more familiar practice than cycling. It necessitates more muscle mass to function against gravity. As a result, PVO_2 on the treadmill is 5%–10% higher than on a cycle ergometer [5,6]. Treadmill walking with your hands on the handrails lowers the metabolic cost and should be avoided if at all necessary. With improved metabolic cost quantification, a cycle ergometer is less likely to cause noise. It is generally less expensive and takes up less space than a treadmill.

During exercise testing, patients with heart disease are subjected to constant ECG monitoring and repeated blood pressure tests. Since oral contact is typically difficult with the mouthpiece apparatus, the patient usually communicates with hand signals during exercise [5,6].

During an exercise-based stress test (CPET tests), respiratory oxygen uptake (VO_2), peak oxygen assimilation, respiratory switch ratio, carbon dioxide production (VCO_2), and ventilator aerobic ratio are measured for this state.

5 Oxygen assimilation

VO_2 (oxygen assimilation) is regulated by cellular oxygen demand up to a point where it equals the maximum rate of oxygen transport. As external work increases, one or more of the determinants of VO_2 approach limitation, and the relationship between VO_2 and work rate can begin to plateau. The strongest proof of VO_2max has traditionally been this VO_2 plateau. Genetic factors, age, sex, body size, and the amount of exercising muscle are the key determinants of PVO_2 [6]. The patient's preparation and encouragement may also have an effect on PVO_2. PVO_2 should be

expressed as a percentage of the expected value and in absolute values (1/min). PVO_2 values can range from 15 times the resting value (30–50 mL/kg/min) [6]. VO_2 can rise from a resting value of about 3.5 mL/kg/min to PVO_2 values of about 15 times the resting value (30–50 mL/kg/min).

6 Respiratory switch ratio

The gas exchange ratio, also known as the respiratory exchange ratio, is the ratio of carbon dioxide emission to oxygen absorption (VCO_2/VO_2) (RER). The RER equals the RQ (respiratory quotient) in a steady-state situation. The RQ value is determined by the fuels used in metabolic processes.

An RQ of 1 indicates metabolisms primarily of carbohydrates.

RQ < 1 indicates a mixture of carbohydrate with fat (an RQ of about 0.7) and protein (an RQ of about 0.8).

RER is a rough indicator of metabolic events. During exercise, the RER rises due to either buffered lactic acid or hyperventilation (usually at the end of the workout) [7].

7 Ventilator anaerobic ratio

The anaerobic ratio, formerly known as the ventilator anaerobic threshold, is used to estimate the exercise ability. Expired ventilation rises linearly with respect to VO_2 and represents aerobically generated CO_2 in the muscles during CPET, which lasts until 50%–60% VO_2max is reached. Since oxygen supply cannot keep up with the increased metabolic demands of exercising muscles, anaerobic metabolism occurs during the second half of the exercise. A substantial rise in blood lactate concentration and lactic acid production in the muscles occurs at this time. The lactate threshold corresponds to the VO_2 level at the start of blood accumulation. The VAR is a valuable metric since work at this stage covers the majority of everyday activities. Since patients who fatigue before hitting VAR are more likely to have a noncardiac problem, the ability to achieve the VAR may help distinguish between cardiac and noncardiac causes of exercise limitation. There are a number of strategies for addressing the VAR, which can be categorized as invasive or noninvasive. For the intrusive estimate of the VAR, direct blood sampling may be used. Since the function of the point of growing lactate necessitates multiple blood samples, it is rarely used in clinical applications. When this approach is used, the VAR is described as the VO_2 at which blood lactate levels begin to rise or, finally, when bicarbonate levels begin to fall. On the other hand, the exact meaning is still up for debate. The pattern of change in VCO_2 and

VE is measured using this noninvasive approach. As workout strength increases, this is proportional to VO_2.

While exercise-based intervention programs are recommended for cardiovascular prevention, different exercise parameters, such as intensity, duration, and frequency, may have a variety of effects on cardiovascular metabolic endpoints. Furthermore, there are interindividual differences in response to different forms or intensities of exercise, which may explain why some studies show similar findings with different types of exercise modalities. Exercise training research is being done now and in the future as well [6]. The effects of exercise-based CR on the progression of cardiovascular disease have been consistently positive. Recent research has shown that training impact varies greatly at the individual level, with up to a third of patients failing to display a substantial improvement in exercise ability despite sufficient compliance. An understanding of the variables and processes controlling the reaction to activity in bodies apart from the skeletal muscles, the heart, and the spinal cord, as well as their interaction at a systemic level, is required to enhance the effectiveness of fitness CR. Presently, cardiac recovery methods are used in cardiac prehabilitation, but they are used proactively rather than reactively. According to comprehensive evidence, such treatments before cardiac surgery may enhance result in a number of domains, including aerobic conditioning, respiratory muscle preparation, lifestyle improvements, diabetic regulation, sleep, and psychoeducation [6] (Table 2).

8 Positive outcomes of cardiac rehabilitation

Cardiac rehabilitation has been shown to have a number of positive results in properly chosen patients. Hypertension, hypotension, and nausea are all signs that have been diminished. Both fitness efficiency and physical activity engagement have increased. The standard of living has also improved. The number of people admitted to the hospital has decreased. About half of the decline in cardiac mortality is believed to be attributed to dietary improvements in stroke risk profiles. Exercise-only cardiac rehabilitation services resulted in a 27% decrease across all fatalities as compared to control program. The results of cardiac recovery in patients who have had a bypass and pericardial effusion surgery are poorly understood due to a lack of trial data. According to one study, cardiac recovery improves VO2max by 50% after a transplant. Following valve replacement surgery, patients who underwent cardiac rehabilitation showed a 25% improvement in VO2max and a 25% increase in functional ability. In the general population, it is unclear if cardiac recovery improves survival [9].

Prehabilitation is the process of improving an individual's functional ability so that he or she can survive a traumatic incident. Individuals are

TABLE 2 Measurement of performance from a cardiac rehabilitation program based on the following criteria: [1,8].

Performance measure	Goal	Intervention
Blood pressure control	< 140/90 mmHg or < 130 mmHg (diabetic patient)	Lifestyle moderation; drug
Diabetes control	AIC < 7%	Patient education, diet planning, BMI, and physical activity programming
Depression	Assess for the presence of depression	Use of a suitable screening method in combination with the required interference
Exercise capacity	Determine if you have a low patience for exercise	Each patient's exercise prescription is special
Lipid control	For patients with a heart condition LDL cholesterol level of 100 mg/dL	Lifestyle moderation; drug
Physical activity	30 min/day 5 days/week	Self-directed resistance training activity is customized to each person's unique needs and desires
Prevention medication	Taking preventive medications as prescribed	Preventive counseling and intervention for people of all ages and gender
Tobacco intervention	Cession of prohibition	Tobacco cession strategy
BMI	A BMI of 18.5–24.9 kg per m^2 and a waist circumference of 40 in. for men and 35 in. for women are recommended	Dietary modification, physical activity programming, and psychological support are all part of a multidisciplinary program

prepared to weather the storm of their activities and to stop or resolve applications by prehabilitation. The preparatory time is regarded as a teaching opportunity. Prehabilitation models should typically include three phases of screening, intervention, tracking, and postintervention evaluation for the benefit, as well as a high level of patient encouragement to improve behavior for preoperative benefits. All patients undergoing major surgery will benefit from prehabilitation, but the duration and severity may differ. To promote behavior change prior to surgery, the multidisciplinary team makes each touch count. Physical activity, inspiratory muscle conditioning, smoking, alcohol, diet, and psychological factors are all factors that are linked to prehabilitation strategies. The aim of inspiratory muscle training is to strengthen breathing muscles and lower the

risk of preoperative pulmonary complications. It is preoperative smoking cessation, preoperative alcohol-adjusted consumption of nonhazardous alcohol, preoperative management of anxiety and depression, and development of self-effectiveness for prehabilitation and surgery, and preoperative nutrition.

Physiological factor may affect rehabilitation as follows:

8.1 Aerobic capacity

In terms of physical activity, the purpose of prehabilitation is to increase aerobic ability. Increased frequency physical activity rehabilitation systems are used in patients with stable coronary artery disease and heart disease. Improved exercise efficiency and hemodynamic gain more than moderate-intensity exercise training, with no substantial increase in complications. This modality's exercise protocols differ. In one study, a 10-min warm-up at 50%–60% VO_2max was presented in the form of 4-min periods at 90%–95% maximum cardiac output (Rate of Perceived Exertion 171), with periods split by three-minute cycles of walking at 50%–70% peak cardiac output [8,10].

8.1.1 Expected outcomes

- A 5%–10% increase in cardiorespiratory fitness, flexibility, muscular endurance, and strength.
- Symptoms are lessened, and physiological responses are lessened.
- An increase in psychological well-being.

8.2 Nutrient

Prior to surgery, the main objectives of nutrient prehabilitation are to optimize nutrient stores and aerobic reserve, as well as to provide an enough reserve to substitute for the aerobic response of serious trauma or injury. Acutely replacing dietary deficiencies is not the same as nutritional prehabilitation. The nutritional intervention involves the timeline that begins with the consideration of surgery and continues through the preoperative and postoperative phases to ensure early patient involvement. The importance of moving away from reactive to proactive nutrition evaluations and action must be stressed. Nutritional therapies are less well studied, and when they are, it is usually in conjunction with exercise as part of a prehabilitation program. These promising preliminary findings warrant further investigation, with a focus on fine-tuning approaches, elucidating mechanisms, and assessing correlations between therapies and large-scale clinical efficacy trials [10].

8.2.1 Expected outcomes

Changes in risk factors are linked to an unhealthy or insufficient diet.

8.3 Smoking

Smoking status is strongly linked to how people use CR. Smokers seem to be less interested in attending even a regular CR training, and those that do participate are often more likely to break out. Addition to stopping smoking should be a priority. Priority is given to patients while they are in hospital. To provide extra assistance in the hospital, a variety of techniques may be used. For stop smoking, medications drugs and nicotine pharmacological intervention referrals to smoking cessation services may be given to patients. Smoking cessation assistance should be available during the prehabilitation program. This could be delivered in the form of community, consultations in learning, and focusing on cessation assistance, including specific targeting. In the case of a relapse, daily monitoring and deep obey and assistance is in place. Intensive ongoing counseling for smoking cessation should be available in the prehabilitation services. This could be achieved through group health teaching focused on cessation support, with personalized therapy available if appropriate, pharmacotherapy assistance if needed, and regular contact with long-term accept and assistance in the event of a repeat. The availability of an intensive cessation support network could entice more smokers to enroll in the program, and the increased support for cessation they receive could enable them to stay in the program longer [8].

8.3.1 Expected outcomes

It has the potential to improve smoking cessation for a long time.

8.4 Alcohol drinking

When compared to abstinence and heavy consumption, reasonable alcohol intake (1–2 drinks/day) is linked to lower cardiovascular and all-cause mortality. According to a collective estimation from approaching longitudinal studies of patients with coronary heart disease, patients who consumed the modest improvement quantities of alcohol daily had a 20% reduction in heart failure (relative risk 0.80, 95% confidence interval [CI] 0.78–0.83) compared to nondrinkers. When we look up the data regarding alcohol intake, it is represented by the J-shaped curve with a considerable added safety against cardiovascular mortality at approximately 25 g/d and significant maximum protection against all-cause mortality at 6–11 g/d. The quantity and pattern of alcohol consumption tends to be further significant than the form of alcohol consumed. HDL is enhanced by promoting the production of apo A-I and A-II in the liver, lowering

fibrinogen levels, increasing fibrinolysis, reducing inflammation, and suppressing platelet activation, which are all possible reasons for the benefits of moderate alcohol intake [11].

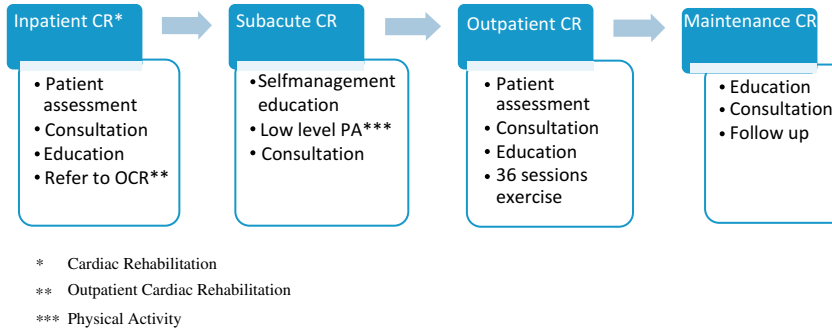
8.5 Behavioral and technical problems management

Personal and behavioral problems are common among heart patients, and they can have an effect on both morbidity and mortality. Following a myocardial infarction, up to 20% of patients experience depression, anxiety, and denial. Patients are routinely screened for nervousness, insomnia, and drug addiction, and family or other social justice issues are just some of the issues that people face during cardiac rehabilitation follow-up. In cardiac rehabilitation center, social workers and other experts on the multidisciplinary patients are given the tools and help they need in order to prepare for their workplace and daily routine. Clinical, behavioral, and cultural therapies tailored to the individual are available; they have been revealed to improve health.

The Interheart Research clearly showed that stress, after lipids and smoking, is one of the most significant risk factors for cardiac incidents. Social anxiety is responsible for 30% of the population's risk of myocardial infarction, which affects the progression of cardiovascular disease by increasing blood glucose, cholesterol, lipid profile, and body mass [11,12]. Atherosclerosis, inflammation, and endothelial dysfunction are all accelerated by it. Exercise training has been linked to lower stress levels and, as a result, lowers mortality rates. Several cardiac treatment services also have workshops on stress control to assist patients in recognizing, avoiding, and dealing with traumatic conditions. Cardiac rehabilitation is thus an effective therapeutic intervention for cardiac patients in distress. Numerous cardiac rehabilitation centers provide further anxiety control technique instructions, such as consideration, relaxation inhalation, and yoga, in addition to exercise [11].

8.5.1 Expected outcomes

The psychological sense of enough and a sense of well-being or the quality of life can be improved by reducing psychological difficulties or by acquiring stress management skills.



Prehabilitation aims to enhance these health metrics, such as endurance, in order to improve postoperative recovery and preserve physical function. During the preoperative screening cycle for elective procedures, it is the best time to create a prehabilitation program. At this stage, a multidisciplinary team composed of medicine, gerontology, anesthesia, surgery, dietetics, kinesiology/physiotherapy, and nursing will recommend a risk stratification model and determine the form and length of prehabilitation required to balance the potential benefit of such intervention against the potential harm of delaying surgery [13].

9 Risk factor for prehabilitation

All patients undergoing major surgery will benefit from prehabilitation, but the duration and severity may differ. A tiring system has been proposed [9]. Educational elements underpin cardiac and pulmonary recovery, with the aim of improving patient awareness of their conditions and the benefits of lifestyle changes. This is one way to improve a patient's self-efficacy. The transition from this to other major-surgery "surgery school" is now a key component of many prehabilitation programs. Patients are better equipped to participate in prehabilitation programs and improved recovery pathways if they are informed and perceptions of the preoperative period are managed [13].

10 Phases of cardiac rehabilitation

Cardiac recovery is divided into four stages. After your cardiac event, the first phase takes place in the hospital, and the remaining three stages take place in the home or in a cardiac treatment facility.

* Cardiac Rehabilitation
** Outpatient Cardiac Rehabilitation
*** Physical Activity

10.1 Phase 1

Acute phase Step 1 occurs when a patient is admitted to the hospital for an acute MI or another type of coronary incident. Throughout that time, the patient is subjected to appropriate regular exercise that is monitored and planned. However, hospitalization, clinical practice, potential risk adjustment, and treatment planning using close to zero multistage fitness tolerance testing are common. This is the first step that occurs during a cardiac incident. This process primarily aids at the beginning of mobility, determining the resilience and the effect of simple functional flexibility on the heart muscle, which are among the first targets of phase 1 cardiac rehabilitation. Prescribe healthy exercises to aid in the improvement of mobility and cardiac health. If an individual has had open-heart

surgery, medical personnel should be consulted. Trigger factors for heart events are being monitored. Patients and their families should be informed about their condition as well as the potential advantages and risks of a cardiac rehabilitation program. An individual may enter the second phase after a sufficient amount of time has passed and substantial healing has occurred.

10.2 Phase 2

The early outpatient phase of cardiac recovery is known as the subacute phase. The patient participates in a controlled regimen of physical exercise, diet therapy, behavioral support, and relative risk change during this period after being discharged from the hospital. To improve patient adherence, a program located in specialty clinic, a part of a hospital, or a cultural center can be constructed in the residential home. Cardiopulmonary recovery can take anywhere from 2 to 7 weeks and includes ongoing monitoring of the heart's reaction to exercise and activity. This step focuses on educating participants on correct workout techniques and how and when to consciously your heart rate and level of exertion when exercising. The individual ought to be able to start to do more individual research and operation at the end of phase 2.

10.3 Phase 3

Phase 3 of intensive outpatient therapy is aimed at maintaining lifestyle improvements made in phases 1 and 2. During step 3, the patient's symptoms, risk factor drug usage, and psychosocial support are all evaluated on a regular basis. The individual must be able to monitor his or her own pulse rate, simply a symptom stress response, and estimated exhaustion level (RPE). During this process of cardiac therapy, a personal trainer would be available to assist in improving exercise capacity and controlling any detrimental changes that might arise. The physical therapist helps customize a regimen of exercises, including agility, mobility, and strength training, as the individual becomes more confident during stage 3 of cardiovascular recovery.

10.4 Phase 4

Stage 4 is a self-governing upholding stage. Independent fitness and conditioning are critical for maintaining good health and avoiding any future heart complications. If a person has completed all three stages, he or she should have a thorough understanding of the disease, risk factors, and strategies for maintaining optimal health. Family physicians play an important role in all three stages of cardiac recovery by ensuring patient continuity; they also help to enhance the quality of life [14].

11 Is rehabilitation too late?

The effect on the result per day in CR remain time was determined using CR timing (i.e., the time among recommendation and begin of core CR) as a nonstop variable. A separate study looked at the effect of CR time as per the current guidelines for "early on" or "late" CR, which is described as starting within 4 weeks of recommendation.

For this, the following CR timing parameters were formed:

- early CR (0–27 days);
- late CR (27–365 days).

In certain circumstances, some patients began the CR in later age, mostly older persons tended to do so. Female, with a lower BMI, at minimum one comorbidity, high systolic blood pressure low diastolic blood pressure, and a low amount of exercise at the moment (less than 150 min per week), has a shorter baseline ISWT distance (all $p < 0.05$). Patients with MI-PCI (myocardial infarction-percutaneous coronary intervention) made up the majority of the participants in both the CR grades (early and late). In terms of patient improvement after CR, late CR attendees saw a smaller benefit for all fitness-related outcomes. Out of 100 people, 63% are identified as slow starter in CR; the average time it takes for a CR applicant to become a CR as per guidelines, it is 39 days. The percentage of MI, MI-PCI, PCI, and CABG patients who were delayed was 69% for MI, 64% for MI-PCI, 56% for PCI, and 63% for CABG patients.

The median wait times (days) for each patient group were compared with the recommended wait times (28 or 42 days for CABG). The median wait time exceeded the recommended maximum waiting time in each patient group; moreover, the post-MI population's median wait time exceeded the highest optional wait time, which was 12 days. Following several analyses, it was discovered that the duration of delayed cardiovascular recovery was a significant independent reason for lower fitness levels as compared to early CR. CR timing was also an important indicator when used as a variable. Latest cardiac care guidelines and articles suggest starting CR as early as possible whenever feasible. Comorbidity burden could be one reason because of the higher percentage of late comers. Compared to 69% of early CR attendees, 73% of late CR attendees had one comorbidity. The complexity of the case can cause a delay in the start of recovery. Difference in time interval among classes is concerning.

Post-MI patients belonged to another patient category. The median minimum wait time was well surpassed by the largest number of days (12 days). This may appear to be counterintuitive, given that post-MI patients do not undergo invasive revascularization operations, which may postpone the start of CR due to the recovery time. Pre-CR to post-CR changes in terms of fitness-linked outcomes were observed regardless of

CR timing. However, in late CR attendees, the level of change was limited. There are two methods used to investigate the effect of cardiovascular rehabilitation timing: for this continuous measure to investigate the connection between escalating wait time and outcome, and timing as a categorical measure (early/late) to investigate the relationship in the form of current guidelines. CR timing was found to be an important predictor of patient outcome in terms of fitness level in each strategy. According to these findings, delaying CR reduces the probability of reporting a positive physical activity level and health outcome. According to the recent study of CR patients, it is found that delayed enrolment is linked to improved patient outcomes [14].

The protection of early enrollment in CR was recently investigated in cardiovascular patients, with no significant difference in main incident rates between early and late enrolls. Aside from clinical results, additional research indicates that the timing of CR enrollment can have an effect on initial CR enrollment. A second study using routine patient records found a correlation between wait time and enrollment. The observed connection between CR timing and treatment outcomes in results of these findings supports the need for timely CR as prompted by current guidance. Since there is a clear correlation between exercise-based CR and lower mortality, avoiding any potential causes of suboptimal fitness shift is important. While it is understood that CR timing should be determined on a one-to-one basis, caution should be exercised to avoid unnecessary delays, such as long waiting lists [14].

12 A paradigm shift in cardiopulmonary rehabilitation

This will be linked to the patient, payer, physician, hospital, and societal health-care-financing preferences. Physical therapists and other rehabilitation providers will play an important role in the incorporation of health promotion in the changing paradigm change from illness and impairment prevention to secondary condition prevention in people with disabilities. Excess weight, as measured by body mass index, is linked to a higher risk of repeated coronary events after a heart attack, particularly in obese people. Jayawardena et al. describe how they used the "plate model" as a dietary intervention for cardiac rehabilitation [15,16]. The "plate model" is a practical way to defy the latest dietary pattern by through standard serving sizes of staple foods in daily courses while still having enough veggies and proteins. The intervention group lost substantially more weight than the control group ($P = 0.029$) over the 12-week follow-up period (intervention group: 1.27 3.58 kg; control group: 0.26 2.42 kg). Additionally, the intervention community saw a nonsignificant reduction in blood pressure and lipid levels. Just 15%–50% of CR patients continue to exercise 6 months

after CR, and even fewer do so after 12 months. About half of patients who smoked prior to a coronary incident continue to smoke 6 months later, and less than half of obese patients adhere to dietary guidelines. As a result, there are a few methods to obtaining the beneficial effects of healing. Patients will further integrate what else they have experienced throughout CR when they have a similar obey [15,16].

Cardiovascular toxicity and therapeutic modalities targeting cardio-oncology: From basic research to advanced study

In view of the growing clinical and healthcare relevance of cancer survivors who are at an elevated risk of dying from cardiovascular diseases, *Cardiovascular Toxicity and Therapeutic Modalities Targeting Cardio-Oncology: From Basic Research to Advanced Study* analyzes the emerging field of cardio-oncology by reviewing the recent advancements in the field (how to monitor and treat cancer survivors for cardiotoxicity) and by identifying potential cardiac side effects in novel cancer therapies. By adopting a translational approach, the book first comprehensively covers the basic science, mechanisms, and concepts, followed by advanced state-of-art of cardio-oncology. This book begins with a brief introduction to cancer and cardiovascular diseases in cancer patients as well as the changes observed in the cardiovascular system, which serves to provide a deeper understanding of therapeutic approaches targeting cardio-oncology. The book then looks into the pathways and inhibitors involved in cancer immunology, as well as the biochemistry of tyrosine kinase inhibitors, anthracyclines, and biomarkers in cardiotoxicity induced by chemotherapeutic drugs. This book then concludes with clinical-focused chapters, including noninvasive cardiovascular imaging techniques, radiotherapy-induced cardiovascular risk, cardiovascular complication from cancer therapy, novel anticancer drugs related to cardiotoxicity, and principles of cardiovascular rehabilitation.

Written by leading researchers in various disciplines, the book serves as a valuable resource to those who are new to the field as well as to various other specialized scientists, researchers, oncologists, cardiologists, physicians, and ancillary staff.

Key Features

- Adopts a translational approach and comprehensively covers the basic science, mechanisms, and concepts, followed by advanced state-of-art of cardio-oncology
- Outlines the current knowledge of biomarkers in cancer therapy-related cardiotoxicity
- Provides improved understanding of the mechanisms of cardiovascular toxicity of various therapies that may lead to the identification of novel targets to reduce vascular complications while providing biological insights into cardiovascular pathophysiology and informing new platforms for drug discovery

About the Editors

Dr. Imteyaz Qamar is Assistant Professor at the School of Biotechnology, Gautam Buddha University, Greater Noida, India. His research focuses on stress biology and cancer genetics. He has written various manuscripts, grants, progress reports, pre-IND protocols, and animal protocols and published them in journals of international repute. He has also received various awards such as the Best Research Presenter Award (2007) from Brain Korea 21, Bharat Vikas Award (2016), Young Scientist Award (2017 and 2019), and STE Meritorious Award (2019). He serves as a member of editorial boards of various peer-reviewed journals. He is also a member of the Endocrinology Society, United States.

Dr. Pawan Kumar Maurya is Professor and Head in the Department of Biochemistry, Central University of Haryana, India. He has more than 13 years of teaching and research experience. His research focuses on biochemical diagnostics, nanomedicine, and clinical biochemistry. He has published more than 112 research articles in reputed journals. He has also edited of three books published by Elsevier, USA, and Springer-Nature, Singapore. He is the recipient of prestigious fellowships such as Science without Borders (Government of Brazil) and National Science Council, Taiwan.

Contents

1. Trauma of negotiating between Language & Space in Postcolonial Literatures in English: Interpreting Shanta Acharya and Bharati Mukherjee.....5
Gargie Bhattacharya

2. From Conflict to Healing: An Analysis of the Trauma of Punjab Insurgency and the Indian Government's Restoration Initiatives.....18
Mayank Rohitashva Garg

3. Treating Psychological Trauma in the Female Character of Anita Desai's *Voices in the City* through Intrapersonal and Interpersonal Communication.....29
Dr. Anjana Tiwari and Dr. Kiran Haribhau Rakibe

4. Nazism as an Ideology.....43
Prof. Poornima Kaushik

5. Indian Partition narratives: An attempt of reinvestigating Trauma theory.....53
Dr. Tushar Chhabulal Patil

6. A Critical Study of Trauma Theory in William Golding's *Lord of the Flies*.....62
Prof.B.K.Patel and Dr.Pramod Kumar Shukla

7. A Study of Trauma in Bonnie Garmus's *Lessons in Chemistry*.....72
Dr. Sanju Choudhary

8. Surviving Through Trauma: An Emotional Death in Reference to Vera Brittain's Memoir *Testament of Youth*.....80
Dr. Sarla Singla

9. *The Glass Palace* by Amitav Ghosh: Eco-Grief Unveiled.....89
Prof. Dr. Veena Nare and Dr. Sharayu Sonawane

10. Holocaust – The Hollowness of humanity: An analysis of the works of the Survivors.....97
Ms. Ankita Verma

11. Derangement and Paranoia in "The Vietnam Project" from *Dusklands* by J. M. Coetzee.104
Dr.Snehlata Tailor

12. A Transactional Analytical Reading of Nagarkar's *God's Little Soldier*.....112
Dr.Susan Lawrencia Jackson V.J

13. The Study of Trauma as depicted in the Indian Regional Literature.....120

Munish Kumar Thakur

14. *The God of Small Things*: A Study of Trauma.....128
Dr. Bharati S. Rajebhosale and Dr. Narendra V. Deshmukh

15. The Scars of War and Migration: Understanding the Trauma Experienced by Displaced Populations.....139
Dr. Girija Joshi and Dr. Deepshikha Parashar

16. Exploring Trauma in the Hybrid Narrative of Doris Lessing's *Alfred and Emily*.....157
Dr. Kopal Vats

17. Critical and Feminist Perspective in the Study of Trauma Associated with War.....167
Dr. Karthiga S.V. and Dr. Manju Roy

18. Paradigms of Survival: Delineating the Quest for Identity and Survival Strategies of Migrants in Monica Ali's *Brick Lane*.....175
Dr. Anjana R B , Bhagya V J, Rukmini Sarma

19. Bhagvad Gita as Therapeutic Tool in Indian English Fiction: A case study of Arun Joshi's *The Foreigner*.....181
Dr. Anita Yadav

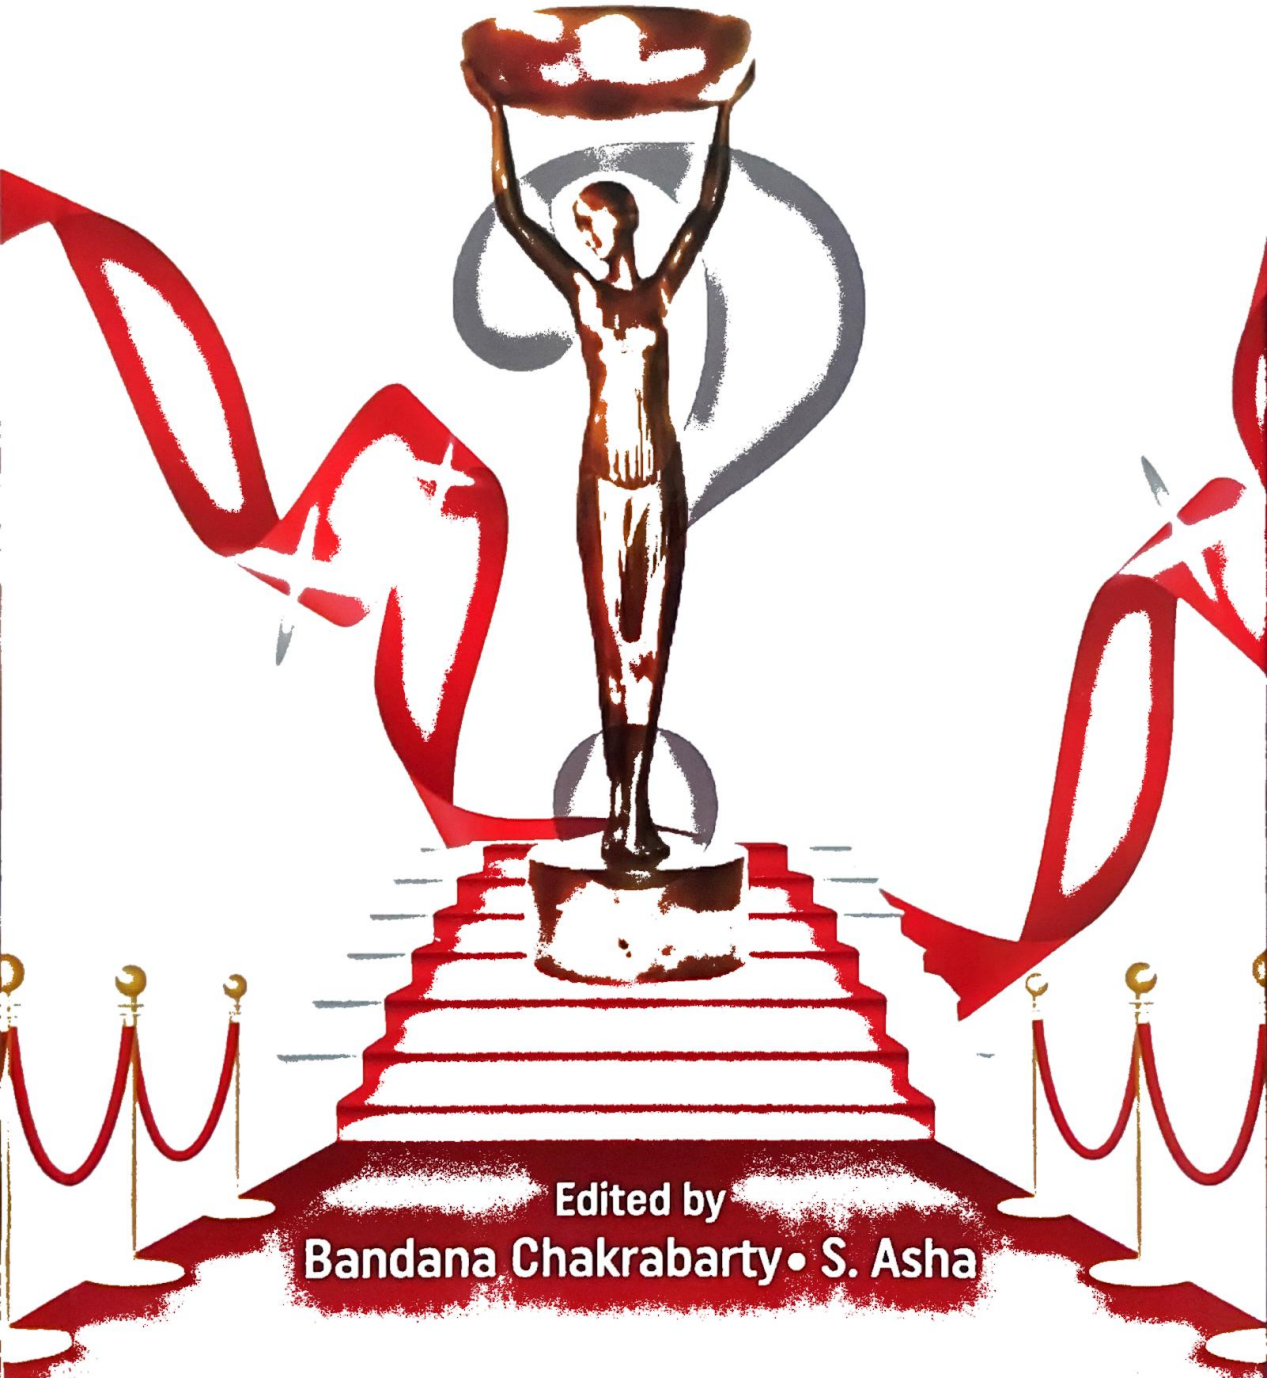
20. Trauma and its overwhelming effects in Alan Duff's *Once Were Warriors*.....194
Ms. Richa Tiwari

21. Theories of Cultural Trauma.....204
Dharmishtha Oza

22. Body, Violence and Trauma in the World of Toni Morrison: A Feminist Study.....216
Arunima Singh

23. A Re-reading of the Paradigm shift of Gendered Roles and Emotional Trauma in Mahasweta Devi's *The Hunt*.....224
Dr. Poonam Rani Gupta

24. War's psychological effects and post-survival.....231
Ms. Jayashree Khade



25. Traumatic Stress of Displacement in Bharti Mukherjee Select Works.....245
Dr. Isha Seegar

26. Reflection of Socio-Political Trauma in Fragmented Feminine Self in *I Am Malala* by Malala Yousafzai.....259
Dr. Yashoda Verma

Who Deserves the Booker? Critiquing the Legacy is a comprehensive anthology on the coveted literary award the Booker Prize. Of the extensive list of the winners over six decades, six of them being Indians, including the latest awardee Geetanjali Shree, their works have become a subject of exploration. The essays in the present volume include awarded writings across the globe and make an honest attempt to critique these works. Today, literary awards provide a public platform for the appreciation of writers and their works, help them gain recognition and provide them with financial support to continue their work. The Booker Prize, previously known as the Man Booker Prize, is a literary award for the best English novel of the year published in the United Kingdom or Ireland. The winner of the Booker Prize is selected by a panel and receives £50,000. The present anthology comprises a collection of twenty-five articles contributed by eminent scholars as well as young and enthusiastic researchers who critique the rich legacy of the Booker Prize. The articles cover a span of six decades providing deep insight into varied themes which are subjects of universal concern. The book will open up doors to further study on such literary awards. It will be a valuable treasure house for further explorations both by researchers and scholars.

Bandana Chakrabarty, an independent scholar has an experience of over thirty seven years of teaching English in various Government Colleges of Rajasthan. Former Joint – Director(Academic) in the Commissionerate of College Education, Jaipur and as Principal of Rajasthan School of Art, Jaipur, she has been instrumental in organizing several Academic activities. Author of *Fictions of the Self: Alice Munro* she has co-edited several anthologies.

S. Asha has been Professor in Government College Tonk. She has a teaching experience of over thirty years in various Government Colleges of Rajasthan. She also has had administrative experience. Her research papers have been published in various journals and books. She has presented papers in International Conferences both in India and abroad. She has authored *Harold Pinter's Screenplays* and has co-edited an anthology titled *Embracing Glocal English*. She in the Vice-President of ELT@I Rajasthan Chapter. She has been a part of all the Conferences and workshops organized by the chapter and conducted several workshops.

भूमिका

छायावादी कवियों और उनके काव्य को लेकर कुछ गहन अध्ययन और उस पर लेखन की इच्छा लंबे समय से थी। वर्ष 2019 की फरवरी में जब सूर्यकांत त्रिपाठी 'निराला' की कविता पर संगोष्ठी आयोजित की, तब से यह इच्छा और बलवती होती गई किंतु प्रत्येक कार्य के होने या करने में हमारा वश कहाँ चल पाता है। राष्ट्रकवि दिनकर ने लिखा है—''यह सब उनकी कृपा, सृष्टि जिनकी निगूढ़ रचना है, झुके हुए हम धनुष मात्र हैं, तनी हुई ज्या पर से, किसी और की इच्छाओं के बाण चला करते हैं।'' अतः स्पष्ट है कि प्रत्येक कार्य का आरंभ और पूर्णता सभी कुछ नियत होते हैं और शायद उसी नियत के कारण इस पुस्तक का लेखन और प्रकाशन टलता रहा। वास्तव में इस विषय पर पुस्तक लेखन का विचार उस समय आया, जिस समय हम छायावाद का शताब्दी वर्ष मना रहे थे। पर वह केवल विचार मात्र ही रह गया। समय-समय पर संशोधन और परिवर्धन भी होते रहे और प्रकाशन तक आते-आते वर्ष 2022 आ गया। यह विचार अब इस पुस्तक का रूप ले पाया।

इस पुस्तक का लेखन-काल बड़ा ही कठिन और पीड़ादायी रहा है, मेरे व्यक्तिगत जीवन के लिए भी और संपूर्ण संसार के लिए भी। व्यक्तिगत वेदना ने मेरे हृदय के कितने टुकड़े किए होंगे, नहीं कह सकता। उन टुकड़ों को खोजना, एक साथ करना और पुनः एक सही आकार देना न मेरे वश का है और न ही संसार में किसी और के वश का। ऐसे में जब मैं अपने टूटे दिल से पीड़ा में डूबा था, तब वेदना एवं करुणा के भावों को और अधिक गहराई से समझा। तब यह विचार उमड़-घुमड़कर मेरे मन-मस्तिष्क में आता रहा कि 'पर शेष नहीं होगी मेरे प्राणों की पीड़ा'। पीड़ा के इसी सागर में जब संवेदनाओं की उथल-पुथल मची थी, इसी बीच कोरोना महामारी ने संपूर्ण विश्व को एक बड़े संकट में डाल दिया। अतः यह समय मेरे लिए व्यक्तिगत वेदना से विश्व वेदना की यात्रा का रहा है।

लॉकडाउन की अवधि ने हम सभी को घरों में कैद कर लिया था। छायावाद से जुड़ी कई किताबें पुस्तकालय से बहुत पहले निकलवा चुका था। घर की व्यक्तिगत लाइब्रेरी में भी बहुत पुस्तकें मिल गईं। ऑनलाइन सामग्री ने भी बहुत मदद की और ऐसे में वेदना से गुजरते हुए सबसे पहले महादेवी की रचनाओं को पढ़ा और धीरे-धीरे कुछ लिखने का प्रयास किया। पुस्तक लेखन जैसा विचार नहीं था किंतु लंबी लॉकडाउन की अवधी में धीरे-धीरे इस क्रम को जारी रखा जिससे यह पुस्तक अपना स्वरूप ले पाई।

इस पुस्तक में कुल पाँच अध्याय हैं। पहले अध्याय में छायावाद की सैद्धांतिकी पर विचार है। वहीं आगे के चार अध्यायों में छायावाद के चारों स्तंभ कवियों—प्रसाद, निराला, पंत एवं महादेवी के कृति-व्यक्तित्व की पहचान, पुनर्विचार एवं रचना वैशिष्ट्य की परख करने का प्रयास किया गया है। 'छायावाद' पर उपलब्ध चर्चित पुस्तकों के अध्ययन के बाद इस पुस्तक के लेखन में इस बात को विशेष रूप से ध्यान में रखा गया है कि पुस्तक में वर्णित विषयों का प्रतिपादन सहज और सरल भाषा में हो। साथ ही स्नातकोत्तर से लेकर प्रतियोगी परीक्षाओं के परीक्षार्थियों तक सभी के लिए यह पुस्तक सहायक सिद्ध हो। इसी कारण विद्यार्थियों से जुड़े सभी पाठ्यक्रमों, जैसे—विश्वविद्यालयी पाठ्यक्रम, लोकसेवा आयोग परीक्षाओं के पाठ्यक्रम और नेट-स्लेट आदि परीक्षाओं के पाठ्यक्रमों आदि को ध्यान में रखकर इस पुस्तक का लेखन किया गया है। आशा है यह पुस्तक सभी परीक्षार्थियों के लिए तो उपयोगी होगी ही, साथ ही रुचिवान पाठकों एवं शोधार्थियों के लिए भी सहायक सिद्ध होगी।

मध्यकालीनकृष्ण भक्ति काव्यधाराः प्रमुख कवि और काव्य वैशिष्ट्य

—डॉ. नवीन नंदवाना

भक्ति भारतीय प्राणधारा की आधारभूमि है। सदियों से भारतीय लोकजीवन में भक्ति का शंखनाद सुनाई पड़ा है। अलग-अलग कालखंडों में विविध संतों और भक्तों ने अपने समय की माँग और साधना पद्धति के अनुरूप भक्ति चेतना का बिगुल बजाया। 'भक्ति' शब्द की व्युत्पत्ति 'भज्' धातु से मानी जाती है जिसका अर्थ होता है—भजना। आचार्य रामचंद्र शुक्ल अपने प्रसिद्ध निबंध 'श्रद्धा-भक्ति' में भक्ति को इस प्रकार स्पष्ट करते हैं कि—''श्रद्धा और प्रेम के योग का नाम ही भक्ति है। जब पूज्य भाव की वृद्धि के साथ श्रद्धा भाजन के सामीप्य लाभ की प्रवृत्ति हो, उसकी सत्ता के कई रूपों के साक्षात्कार की वासना हो, तब हृदय में भक्ति का प्रादुर्भाव समझना चाहिए।'' डॉ. धीरेन्द्र वर्मा अपने 'हिंदी साहित्य कोश' में भक्ति के स्वरूप को स्पष्ट करते हुए लिखते हैं कि—''नारद के अनुसार वह 'परमप्रेमरूपा' और 'अमृत स्वरूपा' है, जिसे प्राप्त कर मनुष्य सिद्ध, अमर और तृप्त हो जाता है। ...पाराशर पुत्र व्यास पूजादि में अनुराग तथा गर्ग कथादि में अनुरक्ति को भक्ति कहते हैं।''

हिंदी साहित्य के इतिहास के पूर्व मध्यकाल की प्रधान प्रवृत्ति भक्ति होने के कारण इस कालखंड को भक्तिकाल (1318-1643 ई.) की संज्ञा प्रदान की गई। यह युग अपनी साहित्यिक श्रेष्ठता के कारण स्वर्ण युग की संज्ञा से अभिहित किया गया। इस काल में कबीर, दादू, नानक और रैदास आदि संतों ने अपनी वाणियों के माध्यम से भक्ति के साथ-साथ समाज सुधार की चेतना फैलायी; वहीं दूसरी ओर

सूफी कवियों ने प्रेम तत्त्व के माध्यम से ईश्वर प्राप्ति का मार्ग दिखाया। राम भक्ति धारा के प्रमुख कवि गोस्वामी तुलसीदास ने समन्वय एवं लोकमंगल का संदेश दिया तो सूरदास की अनन्य कृष्ण भक्ति भी लोक प्रसिद्ध है। इस प्रकार इस कालखंड में विविध माध्यमों द्वारा भक्ति की प्रतिष्ठा के व्यापक प्रयास किए गए।

भक्ति-आंदोलन के सूत्रपात के विषय में आचार्य परशुराम चतुर्वेदी का मत है कि—''हिंदू धर्म इस्लाम के संपर्क से मात्र व्यक्तिगत साधना का केंद्र न रहकर सामूहिक साधना का रूप धारण करने लगा था और उसमें आंदोलनकारी प्रवृत्तियाँ उभरने लगी थीं। प्रायः सभी धर्मों में युगानुरूप परिस्थिति के अनुसार पंथों, संप्रदायों और उपसंप्रदायों की सृष्टि होने लगी, जिसका मुख्य उद्देश्य आत्म निरीक्षण और परिस्थिति परीक्षण द्वारा आवश्यक सुधार करके परंपरागत आचार-विचारों को किसी-न-किसी रूप में प्रश्रय दे कर उन्हें जीवित रखना था। इस प्रयास में वैष्णव धर्म ने भागवत संप्रदाय के रूप में नेतृत्व किया और व्यापक प्रभाव डाला, जिसके माध्यम से भक्ति-आंदोलन का सूत्रपात हुआ।''

इस दौर में भक्ति आंदोलन का अखिल भारतीय स्वरूप दिखाई पड़ा। भारतीय वैष्णव धर्म में भक्ति की प्रधानता थी। इनमें आत्मा-परमात्मा के संबंधों को लेकर द्वैत, अद्वैत, द्वैताद्वैत, शुद्धाद्वैत और विशिष्टाद्वैत आदि के आधार पर दार्शनिक चिंतन हुए। इसी प्रकार इस्लाम में शरा और बेशरा, श्रमण धर्मों में बौद्ध व जैन धर्मों में भी उप संप्रदाय जैसे मंत्रयान, वज्रयान, सहजयान आदि का जन्म हुआ। शैवों में भी कश्मीरी, लिंगायत, पाशुपत एवं वीर आदि तथा शाक्तों में वाममार्गी व दक्षिण मार्गी जैसे उप विभाजन हुए। यह सब कुछ भक्ति-आंदोलन के प्रभाव से हुआ। देश के अलग-अलग भागों में और कई संप्रदायों का जन्म हुआ। परशुराम चतुर्वेदी का मानना है कि—''केरल का शास्तापूजक संप्रदाय, बंगाल के धर्म-ठाकुर, सहजिया, बाउल, सत्यपीर और कर्त्ताभाजा आदि संप्रदाय, उड़ीसा का पंचसखा संप्रदाय महाराष्ट्र के वारकरी और महानुभाव-संप्रदाय भक्ति आंदोलन की ही उपज हैं।'' इनके अतिरिक्त गुजरात में नरसी मेहता और राजस्थान में मीरा बाई ने भक्ति का बिगुल बजाया। इस प्रकार भक्ति, आंदोलन का स्वरूप धारण कर देश भर में फैल गई।

विभिन्न परिस्थितियों ने भी भक्ति आंदोलन के उद्भव में सहायता की। आचार्य रामचंद्र शुक्ल अपने इतिहास ग्रंथ में लिखते हैं कि—''देश में मुसलमानों का राज्य प्रतिष्ठित हो जाने पर हिंदू जनता के हृदय में गौरव, गर्व और उत्साह के लिए अवकाश न रह गया। उसके सामने ही देवमंदिर गिराये जाते थे, देवमूर्तियाँ

तोड़ी जाती थीं और पूज्य पुरुषों का अपमान होता था और वे कुछ नहीं कर सकते थे। ऐसी दशा में अपनी वीरता के गीत न तो वे गा ही सकते थे और न बिना लज्जित हुए सुन ही सकते थे।...अपने पौरुष से हताश जाति के लिए भगवान् की शक्ति और करुणा की ओर ध्यान ले जाने के अतिरिक्त दूसरा मार्ग ही क्या था?''

आचार्य हजारीप्रसाद द्विवेदी का मत शुक्ल जी से भिन्न है। उन्हें शुक्ल जी की यह बात ठीक नहीं लगती कि भक्ति आंदोलन का उद्भव मुस्लिम आक्रमणों की प्रतिक्रिया स्वरूप हुआ। वे कहते हैं कि—''मुसलमानों के अत्याचार के कारण यदि भक्ति की भाव धारा को उमड़ना था तो पहले उसे सिंध में और फिर उत्तर भारत में प्रकट होना चाहिए था, पर हुई वह दक्षिण में।'' वे कहते हैं—''अगर इस्लाम नहीं आया होता तो भी इस साहित्य का बारह आना वैसा ही होता जैसा आज है।'' विभिन्न विद्वानों के मतों के अध्ययन के आधार पर कहा जा सकता है कि भक्ति भारतीय प्राणधारा का मूल तत्त्व है जो कि परंपरा से ही भारतीय जीवन का हिस्सा रही है। पूर्व मध्यकाल तक आते-आते यह प्राण धारा अधिक वेगवान और बलवती हुई और ऐसा होने के पीछे विविध सामाजिक, राजनीतिक और आर्थिक परिस्थितियों ने अपनी महती भूमिका निभाई। भक्ति आंदोलन के उदय के कारणों में हमें किसी एक विशिष्ट कारण को आधार न बनाकर समेकित प्रभाव को स्वीकारना होगा।

हिंदी साहित्य का भक्तिकाल विविधतापूर्ण रहा है। विविध संतों और भक्तों ने अपनी-अपनी साधना-पद्धति के अनुसार ईश्वर का स्मरण किया है। यदि संपूर्ण भक्तिकाल पर समग्रता से दृष्टि डालें तो पाते हैं कि ईश्वर आराधना के आधार पर इस काल की भक्ति चेतना को दो भागों निर्गुण भक्ति काव्यधारा और सगुण भक्ति काव्यधारा में बाँटा गया। पुनः इन दोनों काव्यधाराओं में उपभेद दिखाए पड़ते हैं। निर्गुण भक्ति शाखा को ज्ञानाश्रयी और प्रेमाश्रयी भक्तिधारा नाम दिया गया। जिसे संत काव्य और प्रेम काव्य या सूफी काव्य भी कहा जाता है। इसी प्रकार सगुण भक्तिधारा को भी अध्ययन की सुविधा और आराधना पद्धति के आधार पर दो भागों राम काव्यधारा और कृष्ण काव्यधारा में विभाजित किया गया है। आचार्य शुक्ल द्वारा प्रदत्त यह विभाजन हिंदी साहित्य में प्रतिष्ठा पा गया। आजकल इस विभाजन को लेकर विद्वानों के विरोध संबंधी स्वर यदाकदा सुनाई पड़ते हैं फिर भी यह विभाजन आज भी बहुजनमान्य है।

कृष्ण भक्तिधारा : प्रमुख कवि और उनका काव्य

हिंदी की कृष्ण काव्य परंपरा एक समृद्ध परंपरा रही है। इस काव्यधारा के कवियों ने कृष्ण और उनकी लीलाओं को आधार बनाकर विशेषत: ब्रजभाषा में काव्य रचना की। इस काव्यधारा के विविध संप्रदायों यथा- वल्लभ संप्रदाय, निम्बार्क संप्रदाय, हरिदासी संप्रदाय, चैतन्य संप्रदाय आदि के भक्त कवियों ने अपनी ईश्वर आराधना के पुष्प अर्पित किए। इस काव्यधारा के प्रमुख कवि इस प्रकार हैं–

सूरदास

हिंदी के ख्यातनाम कवि और कृष्ण भक्तिधारा के शिरमौर सूरदास का काव्य इस परंपरा की अमरनिधि है। कृष्ण काव्य कहते ही भारतीय लोकमानस में सूर की छवि उभरती हैं। सूर का जीवनकाल 1478 से 1583 ई. निर्धारित किया जाता है। जन्म स्थान को लेकर भी दो मत प्रचलित हैं। कुछ विद्वान आगरा के समीप रुनकता को तो कुछ दूसरे विद्वान दिल्ली के निकट सीही ग्राम को सूर का जन्म स्थल मानते हैं। सूर वल्लभाचार्य के शिष्य थे। उनका शिष्यत्व ग्रहण करने के बाद वे पारसौली ग्राम में चंद्रसरोवर के निकट रहने लगे थे। भक्तमाल के रचयिता नाभादास ने इनके विषय में कहा था कि–"सूर कवित्त सुनि कौन कवि, जो नाहिं सिर चालन करै।" वल्लभाचार्य का प्रभाव इनके साहित्य में परिवर्तन ले आया। उनसे भेंट होने से पूर्व ये विनय और दैन्य के पद लिखते थे किंतु बाद में उनकी प्रेरणा से सख्य, वात्सल्य और शृंगार रसों में पद रचना करने लगे। वात्सल्य वर्णन की दृष्टि से सूर का साहित्य अपना विशेष महत्त्व रखता है। आचार्य रामचंद्र शुक्ल ने इस विषय में कहा है कि–"सूर ही वात्सल्य है और वात्सल्य ही सूर है।"

सूरदास ने 'सूरसागर', 'साहित्य लहरी' और 'सूर सारावली' की रचना की। इनमें से अंतिम रचना की प्रामाणिता संदिग्ध है। 'सूरसागर' की रचना सूर ने भागवत की पद्धति पर द्वादश स्कंधों में की है। वहीं 'साहित्य लहरी' में सूरदास द्वारा रचित दृष्टकूट पद संगृहीत हैं। सूर के निधन पर वल्लभाचार्य के पुत्र विट्ठलनाथ ने कहा था कि–"पुष्टि मारग को जहाज जात है, सो जाकों कछु लेना होय सो लेऊ।"

सूरदास ने भागवत में आए भ्रमरगीत के संक्षिप्त प्रसंग को विस्तार के साथ अपने पदों में वर्णित किया है। भागवत के 10वें स्कंध के 47वें अध्याय में पद संख्या 12 से 21 तक वर्णित भ्रमर गीत का यह प्रसंग सूर की प्रतिभा से उनके पदों में लगभग 400 पदों का विस्तार पा गया। यह भ्रमरगीत प्रसंग हिंदी साहित्य की

अमरनिधि है। इन प्रसंगों में सूर ने निर्गुण का खंडन और सगुण का मंडन किया है–

निरगुन कौन देश कौ बासी।
मधुकर, कहि समुझाइ, सौंह दै बूझति सांच न हाँसी।।
को है जनक, जननि को कहियत, कौन नारि को दासी।
कैसो बरन, भेष है कैसो, केहि रस में अभिलाषी।।
पावैगो पुनि कियो आपुनो जो रे कहैगो गाँसी।
सुनत मौन ह्वै रह्यौ ठगो-सौ सूर सबै मति नासी।।

कुंभनदास

वल्लभ संप्रदाय के अष्टछाप के कृष्ण भक्त कवियों में कुंभनदास का नाम भी उल्लेखनीय है। ये गोवर्धन के समीप जमनावतौ ग्राम में रहकर कृष्ण आराधना करते थे। ये भी वल्लभचार्य के शिष्य थे। इनके रचे पद कांकरोली के विद्या विभाग और नाथद्वारा के पुस्तकालय से प्रकाशित हुए हैं। कहते हैं कि एक बार बादशाह अकबर ने इन्हें? फतेहपुर सीकरी बुलाया था। इनके पदों को सुनकर प्रसन्न होकर इन्हें कुछ माँगने के लिए कहा तो उन्होंने अपनी इच्छा इस प्रकार व्यक्त की–

संतन को कहा सीकरी सों काम?
आवत जात पनहियाँ टूटी, बिसरि गयो हरि नाम।।
जिनको मुख देखे दुख उपजत, तिनको करिबे परी सलाम।।
कुभंनदास लाल गिरिधर बिनु, और सबै बेकाम।।

नंददास

वल्लभ संप्रदाय के अष्टछाप के आठ कवियों में से एक नंददास वल्लभाचार्य के पुत्र विट्ठलनाथ के शिष्य थे। इनके पिता का नाम जीवनराम और चाचा का नाम आत्माराम था। ये ही आत्माराम तुलसी के पिता थे। इस प्रकार नंददास और तुलसीदास चचेरे भाई थे।

अनेकार्थमंजरी, मानमंजरी, रसमंजरी, रूपमंजरी, विरहमंजरी, प्रेम बारहखड़ी, श्यामसगाई, सुदामाचरित, रुक्मिणीमंगल, भंवरगीत, रासपंचाध्यायी, सिद्धांत-पंचाध्यायी, दशमस्कंधभाषा, गोवर्धनलीला और नंददास पदावली आपकी रचनाएँ हैं। हिंदी साहित्य जगत में ये जड़िया के नाम से प्रसिद्ध हैं। इनके विषय में उक्ति

चर्चित है कि—

''और कवि गढ़िया नंददास जड़िया।''

वल्लभ संप्रदाय के अन्य कवि

वल्लभ संप्रदाय के अष्टछाप कवियों में उपर्युक्त कवियों के अतिरिक्त परमानंददास, कृष्णदास, गोविंद स्वामी, छीतस्वामी और चतुर्भुजदास हैं। परमानंददास की रचनाएँ परमानंदसागर, और परमानंद के पद नाम से प्रकाशित हैं। कृष्णदास को अधिकारी के नाम से जाना जाता है। गोविंद स्वामी का पद चयन 'गोविंद स्वामी के पद' नाम से संकलित है।

निम्बार्क संप्रदाय के कृष्ण भक्त कवि

इस संप्रदाय के प्रवर्तक स्वामी निम्बार्काचार्य हैं। हिंदी कृष्ण काव्य परंपरा में निम्बार्क संप्रदाय के कृष्ण भक्त कवियों में इनके अलावा श्री भट्ट, हरिव्यास देव और परशुरामदेव हैं। इस संप्रदाय में राधा के युगल भाव की स्वीकृति है। यहाँ वृषभानुजा राधा के साथ श्रीकृष्ण की आराधना का विधान है। इस संप्रदाय की प्रधान पीठ सलेमाबाद (अजमेर) में है। वेदांतपरिजात सौरभ, दशश्लोकी और श्रीकृष्णस्तवराज जैसे ग्रंथों की रचना संप्रदाय के प्रवर्तक निम्बार्काचार्य ने की। श्री भट्ट जो कि इस संप्रदाय में हितू सखी के अवतार माने जाते हैं। इन्होंने युगल शतक नामक ग्रंथ की रचना की। हरिव्यास देव ने ब्रजभाषा में महावाणी लिखा। वहीं परशुराम देव का ग्रंथ परशुराम सागर है।

राधावल्लभ संप्रदाय के कृष्ण भक्त कवि

कृष्ण भक्ति परंपरा के इस संप्रदाय का प्रवर्तन सन 1534 में वृंदावन में हितहरिवंश ने किया। यहाँ रसोपासना का विधान है। इस संप्रदाय में राधा जी को कृष्ण से भी ऊँचा स्थान दिया जाता है। इस संप्रदाय के मंदिरों में कृष्ण के विग्रह के साथ राधा का विग्रह नहीं होता है बल्कि श्रीकृष्ण के वाम भाग में एक वस्त्र निर्मित गद्दी होती है जिस पर श्रीराधा अंकित किया हुआ एक स्वर्णपत्र रखा होता है। इसे इस संप्रदाय में गद्दी सेवा के नाम से जाना जाता है। इस संप्रदाय के भक्त कवियों में स्वामी हितहरिवंश ने हित चौरासी, स्फुटवाणी की रचना की। वहीं दामोदर दास जो इस संप्रदाय में सेवक जी के नाम से प्रसिद्ध हैं, ने सेवकवाणी लिखा। हरिराम व्यास ने व्यासवाणी और रागमाला ग्रंथों की रचना की। इस संप्रदाय के अन्य भक्त

कवियों में चतुर्भुजदास, ध्रुवदास और नेही नागरीदास के नाम उल्लेखनीय हैं।

हरिदासी संप्रदाय के कृष्ण भक्त कवि

हरिदासी संप्रदाय के कृष्ण भक्त कवियों में स्वामी हरिदास का नाम आदर के साथ लिया जाता है। ये इस संप्रदाय के प्रवर्तक हैं। इस संप्रदाय को सखी संप्रदाय और टट्टी संप्रदाय के नाम से भी जाना जाता है। हरिदास जी ने सिद्धांत के पद और केलिमाल नामक ग्रंथों की रचना की। अन्य भक्तों में जगन्नाथ गोस्वामी, बीठल बिपुल, बिहारिनदास, नागरीदास हैं।

ज्यौंहिं ज्यौंहिं तुम रखत हौं,त्योंहीं त्योंहीं रहियत हौं, हे हरि।
और अपरचौ पाय धरौं सुतौं कहौं कौन के पैंड भरि।
जदपि हौं अपनों भायो कियो चाहौं,
कैसे करि सकौं जो तुम राखौ पकरि।
कहै हरिदास पिंजरा के जानवर लौं
तरफाय रह्यौ उडिबे को कितोऊ करि।।

चैतन्य संप्रदाय के कृष्ण भक्त कवि

चैतन्य संप्रदाय के प्रवर्तक चैतन्य महाप्रभु हैं। जिन्हें गौर या गोरांग के नाम से भी जाना जाता है। इस संप्रदाय को गौड़ीय संप्रदाय भी कहा जाता है। इस संप्रदाय के अन्य भक्तों में रामराय, सूरदास मदनमोहन, गदाधर भट्ट, चंद्रगोपाल और माधवदास माधुरी हैं।

संप्रदाय निरपेक्ष कृष्ण भक्त कवि

अपनी-अपनी साधना पद्धतियों के अलावा हिंदी में मीरा और रसखान ऐसे कृष्ण भक्त हैं जिन्होंने किसी भी संप्रदाय की साधना पद्धति से बंधने के स्थान पर अपने मन की सहज अनुभूतियों को आधार बनाकर कृष्ण आराधना की। मीरा का जन्म 1504 ई. में रतनसिंह के घर मेड़ता के समीप कुड़की ग्राम में हुआ। इनका विवाह सन 1516 में भोजराज के साथ हुआ। मीरा बचपन से ही कृष्ण को अपना आराध्य मानती थीं। अतः उनकी भक्ति माधुर्य भाव की थी। मीरा द्वारा रचित कई ग्रंथों का उल्लेख विभिन्न विद्वान अपनी-अपनी पुस्तकों में करते हैं। किंतु स्फुट पद नामक रचना को मीरा की प्रामाणिक रचना माना जाता है। मीरा साफ घोषणा करती है कि—

मेरे तो गिरधर गोपाल दूसरो न कोई।।
जाके सिर है मोरपखा मेरो पति सोई।
तात मात भ्रात बंधु आपनो न कोई।।
छांड़ि दई कुलकी कानि कहा करिहै कोई।।
संतन ढिग बैठि बैठि लोकलाज खोई।।

अंसुवन जल सींचि-सींचि प्रेम-बेलि बोई।
अब तो बेल फैल गई आणंद फल होई।।

रसखान भी संप्रदाय निरपेक्ष कवियों में चर्चित नाम है। इनका मूल नाम सैयद इब्राहिम था। एक मुसलमान होते हुए जितनी श्रेष्ठता से कृष्ण भक्ति काव्य की रचना की है, वह वंदनीय है। सुजान रसखान, दानलीला, प्रेमवाटिका और अष्टयाम इनकी प्रसिद्ध रचनाएँ हैं। रसखान के पदों का प्रधान रस शृंगार और वात्सल्य है। सवैयों की रचना के लिए रसखान हिंदी जगत में अमर हैं—

मोरपखा सिर ऊपर राखिहौं, गुंज की माल गरे पहिरौंगी।
ओढ़ि पिताम्बर लै लकुटी, बन गोधन ग्वारन संग फिरौंगी।।
भावतो मोहि मेरो रसखान, सो तेरे कहे सब स्वाँग भरौंगी।
या मुरली मुरलीधर की, अधरान धरी अधरा न धरौंगी।।

कृष्ण भक्ति काव्य का वैशिष्ट्य

मध्यकालीन कृष्ण भक्त कवियों ने कृष्ण की लीलाओं का गान अपने काव्य के माध्यम से किया है। इन कवियों ने कृष्ण की माखन लीला, रास लीला, दान लीला, चीरहरण लीला और गोचारण आदि का हृदयग्राही वर्णन किया है। अपनी व्यक्तिगत अनुभूतियों को सरसता के साथ इन कवियों ने अभिव्यक्ति दी है।

मैया मैं नहिं माखन खायौ।
ख्याल परैं ये सखा सबै मिलि, मेरैं मुख लपटायौ।।
देखि तुही सींके पर भाजन, ऊँचौं धरि लटकायौ।
हौं जु कहत नान्हे कर अपनै मैं कैसैं करि पायौ।।
मुख दधि पोंछि, बुद्धि इक कीन्ही, दोना पीठि दुरायौ।
डारि साँटि, मुसुकाइ जसोदा, स्यामहि कंठ लगायौ।।

मध्यकालीन कृष्ण भक्त कवियों ने कृष्ण की लीलाओं के गान में अपनी ओर से मौलिक उद्भावनाएँ जोड़ दी हैं। कृष्ण की लीलाओं का गान हिंदी काव्य से पहले संस्कृत और प्राकृत आदि में हो चुका है। किंतु हिंदी में जो उनका रूप

उभर कर आया है, वह बहुत कुछ नूतन है। हिंदी कवियों ने कृष्ण की बाल लीलाओं को अधिक स्नेह के साथ वर्णित किया गया। ब्रजमंडल में कृष्ण के बीते समय की लीलाओं के साथ किशोर वय में उनके गोपियों और राधा के साथ प्रेम को भी इन कवियों ने मौलिक प्रस्तुति दी है। भागवत की कथा और प्रसंगों को आधार बनाकर भी ये कवि केवल उन प्रसंगों तक रुके नहीं रहे। हर कवि ने अपनी ओर से इन कथा प्रसंगों में कुछ नया जोड़ा है।

बूझत स्याम कौन तू गोरी।
कहाँ रहति काकी है बेटी देखी नहीं कहूँ ब्रज खोरी।।
काहे कों हम ब्रजतन आवतिं खेलति रहहिं आपनी पौरी।
सुनत रहति स्त्रवननि नंद ढोटा करत फिरत माखन दधि चोरी।।
तुह्मरो कहा चोरि हम लैहैं खेलन चलौ संग मिलि जोरी।
सूरदास प्रभु रसिक सिरोमनि बातनि भुरइ राधिका भोरी।।

कृष्ण भक्त कवियों ने कृष्ण की लीलाओं के गान में भगवद् रति का वर्णन प्रमुख रहा है। यहाँ कांता भाव के साथ-साथ वात्सल्य और सख्य भाव की भक्ति द्रष्टव्य होती है। यहाँ हमें रागानुरागा भक्ति के दर्शन होते हैं। वल्लभ संप्रदाय के भक्त कवि अपना सर्वस्व श्रीकृष्ण के भरोसे छोड़ देते हैं। यहाँ वे दीनानाथ की कृपा को ही सब कुछ मानते हैं—

जापर दीनानाथ ढरै।
सोई कुलीन, बड़ो सुन्दर सिइ, जिहिं पर कृपा करै।।
राजा कौन बड़ो रावन तें, गर्वहिं गर्व गरै।
कौन विभीषन रंक निसाचर, हरि हंसि छत्र धरै।।
रंकव कौन सुदामाहू तें, आपु समान करै।
अधम कौन है अजामील तें, जम तहं जात डरै।।

यह गति मति जानै नहिं कोऊ, किहिं रस रसिक ढरै।
सूरदास, भगवन्त भजन बिनु, फिरि-फिरि जठर जरै।।

कृष्ण काव्यधारा के कवियों ने विशेष रूप से शृंगार, वात्सल्य और शांत रस का निरूपण किया है। सूर के आरंभिक पदों में विनय और दैन्य भाव प्रधान था। जब वे वल्लभाचार्य के संपर्क में आए और शिष्यत्व ग्रहण किया तब से अपने गुरु की प्रेरणा से शृंगार, सख्य और वात्सल्य भाव के पदों की रचना करने लगे। विशेष रूप से कहा जा सकता है कि कृष्ण काव्य में ब्रजरस सर्वत्र व्याप्त है। ब्रज की गोपियों और कृष्ण का प्रेम सहज रूप से वर्णित है।

मैया! मैं माखन नहीं खायो।
ख्याल परै ये सखा सबै मिलि मेरै मुख लपटायो।।

उधो, मन न भए दस बीस।
एक हुतो सो गयौ स्याम संग, को आराधै ईस।।

मध्यकालीन कृष्ण काव्य में कवियों ने प्रकृति का भी सुंदर वर्णन किया है। कृष्ण की लीलाओं का अंकन करते समय इन कवियों की दृष्टि ब्रज क्षेत्र की प्रकृति जैसे-वन, उपवन, गोवर्धन पर्वत, यमुना नदी, गोचारण आदि पर भी रही और इन्होंने इनका प्रभावी अंकन किया है।

मधुबन तुम क्यौं रहत हरे।
बिरह बियोग स्याम सुंदर के ठाढ़े क्यौ न जरे।।

देखियति कालिंदी अति कारी।
अहो पथिक कहियौ उन हरि सौ, भई बिरह-जुर-जारी।।

कैसे कै भरिहैं री दिन सावन के।
हरित भूमि भरे सलिल सरोवर, मिटे मग मोहन आवन के।।
दादुर मोर सोर चातक पिक, सूनी निसा सिरावन के।।
गरज चहूँ घन घुमड़ दामिनी मदन धनुष धन धावन के।।

कृष्ण काव्य में वैसे तो संत कवियों और रामकाव्य परंपरा के समान वहाँ के समाज और संस्कृति का वर्णन नहीं आया है, किंतु यहाँ हम ब्रज संस्कृति की उपस्थिति देख सकते हैं। ब्रजमंडल के दैनिक जीवन का वर्णन यथा वहाँ के गोप-ग्वालों की दिनचर्या उभरकर आई है। स्वयं कृष्ण को कवियों ने गाय और प्रकृति से जोड़कर किसान वर्ग के साथ खड़ा किया है। गोवर्धन की पूजा का संदेश भी एक प्रकार से प्रकृति, पर्यावरण और किसान जीवन से जोड़ने वाला है। ब्रज के गीत और रास लीलाओं का वर्णन भी हमें वहाँ की संस्कृति से जोड़ता है। ब्रज मंडल की होली का दृश्य हम इस पद में देख सकते हैं—

खेलत फागु कुँवर गिरिधारी
अग्रज, अनुज, सुबाहु, श्रीदामा, ग्वाल, बाल, सब सखाऽनुसारी।
इत नागरि निकसी घर-घर ते दै आगे वृषभानु दुलारी।
नव सत सजि ब्रजराज द्वार मिलि प्रफुलित वदन भीर भई भारी।

ब्रज मंडल की चरवाहा संस्कृति भी इन कवियों के काव्य में वर्णित हुई है।

इस पद में हम इस संस्कृति की झलक देख सकते हैं—

आजु मैं गाई चरावन जैहों
वृंदावन के भाँति-भाँति फल अपने कर मैं खैहों।

कृष्ण काव्य परंपरा के कवियों पर रीति ग्रंथों के प्रणयन का प्रभाव भी द्रष्टव्य होता है। इन कवियों ने भक्ति चेतना से युक्त ग्रंथों की रचना के साथ-साथ रीति ग्रंथों की रचना में भी अपनी रुचि दिखाई है। सूरदास ने 'साहित्य लहरी' में रीति पद्धति को अपनाया है। इसी प्रकार नंददास की रसमंजरी और रूपमंजरी जैसी रचनाओं में भी रीति निरूपण देख सकते होता हैं।

कृष्ण काव्य परंपरा के कवियों ने कृष्ण की लीलाओं के गान को अपना लक्ष्य बनाया और इस लक्ष्य को आधार बनाकर लगभग सभी भक्त कवियों ने मुक्तक काव्य रूप में कृष्ण की लीलाओं और जीवन चरित का वर्णन किया है। यहाँ प्रबंधात्मक रचनाएँ लेखन की दिशा में इन कवियों ने अपनी रुचि नहीं दर्शायी। इन कवियों का रचना संयोजन और पद लेखन इस प्रकार का है कि यह मुक्तक होते हुए भी प्रबंध सा आनंद देता है। इन कवियों ने गेय मुक्तक शैली को अपनाकर कृष्ण आराधना में पदों की रचना की है।

इन कवियों ने कृष्ण के चरणों में अपने भक्ति पुष्प अर्पित करने के लिए ब्रज मंडल की भाषा ब्रजभाषा को चुना। सभी कवियों ने इसी भाषा में अपने हृदयोद्गारों को अभिव्यक्ति दी है। राम काव्य परंपरा में हमे ब्रज और अवधी दोनों ही भाषाओं में लेखन द्रष्टव्य होता है किंतु कृष्ण काव्य में ऐसा नहीं है। यहाँ सभी कवियों ने ब्रजभाषा में ही लेखन किया है। यह साहित्य इतनी श्रेष्ठता से रचा गया कि ब्रजभाषा भी इस साहित्य के कारण उच्च स्थान की अधिकारिणी हुई। वहीं ब्रजभाषा की सरसता और मधुरता ने इस साहित्य को भी जनप्रिय बनाने में महती भूमिका निभाई।

मध्यकालीन कृष्ण काव्य में कवियों ने अपनी भावनाओं के सुंदर और प्रभावी प्रस्तुतीकरण के लिए छंदों और अलंकारों के प्रयोग पर भी ध्यान दिया। इन कवियों ने अपने काव्य में चौपाई, चौबोला, सार और सरसी जैसे छंदों का प्रयोग किया है। वहीं दोहा, रोला, कवित्त, सवैया के प्रयोग भी किए हैं। रसखान तो हिंदी जगत में सवैया के लिए ख्यात हैं ही।

मानुस हौं तो वही रसखान, बसौं मिलि गोकुल गाँव के ग्वारन।
जो पसु हौं तो कहा बस मेरो, चरौं नित नंद की धेनु मँझारन।।
पाहन हौं तो वही गिरि को, जो धर्यो कर छत्र पुरंदर धारन।
जो खग हौं तो बसेरो करौं मिलि कालिंदीकूल कदम्ब की डारन।।

इस काव्य में उपमा, रूपक, उत्प्रेक्षा, श्लेष, वक्रोक्ति और यमक जैसे अलंकारों का प्रयोग किया है। सूरदास के यहाँ हम इस पद में सांगरूपक का सुंदर प्रयोग द्रष्टव्य होता है—

अब कै, माधव, मोहिं उधारि।
मगन, हौं भव, अम्बुनिधि, में, कृपासिन्धु मुरारि।।
नीर अति गंभीर माया, लोभ लहरि तरंग।
लियें जात अगाध जल में गहे ग्राह, अनंग।।
मीन इन्द्रिय अतिहि काटति, मोट, अघ सिर भार।
पग न इत उत धरन पावत, उरझि मोह सिबार।।

इस प्रकार कहा जा सकता है कि हिंदी का मध्यकालीन कृष्ण भक्तिकाव्य अपना विशेष महत्त्व रखता है। इन कवियों ने अपनी-अपनी साधना पद्धति और सिद्धांतों को अपनाते हुए भी कृष्ण की आराधन की। कृष्ण भक्ति की धारा में इन कवियों द्वारा रचित काव्य हिंदी साहित्य की अमरनिधि है।

भरत के राम

नवीन नन्दवाना

राम सृष्टा भी हैं और सृष्टि भी! राम द्रष्टा भी हैं और दृष्टि भी!
राम एकान्त भी हैं और महफिल भी! राम मार्ग भी हैं और मंजिल भी!
राम जीवन भी हैं और मुक्ति भी! राम युद्ध भी हैं और युक्ति भी!
राम मनहर भी हैं और मनस्वी भी! राम राजा भी हैं और तपस्वी भी!...
राम गृहस्थ भी हैं और सन्त भी! राम आदि भी हैं और अन्त भी![1]

हिन्दी के ख्यातनाम मंचीय कवि कुमार विश्वास की रचना 'अपने अपने राम' की इन पंक्तियों से हम राम की व्यापकता और भारतीय लोक जीवन में राम की उपस्थिति का सहज अनुमान लगा सकते हैं। भारतीय समाज में राम और रामकथा की धारा एक अजस्र स्रोतस्विनी के रूप में सदियों से प्रवाहमान है। इस रामकथा को भारतीय प्राणधारा में सहज स्थापित करने का श्रेय आदिकवि वाल्मीकि और गोस्वामी तुलसीदास को दिया जाता है। इन दोनों ही महत कवियों की रचनाओं ने भारतीय जनमानस में राम के एक श्रेष्ठ रूप की स्थापना की है। आज के दौर में हर व्यक्ति के अपने-अपने राम हैं। वह राम को अलग-अलग रूप में स्वीकार करता है।

वाल्मीकि कृत 'रामायण' से लेकर 'रघुवंश' (कालिदास) में, बौद्ध परंपरा में 'अनामर्क जातक', 'दशरथ जातक', 'दशरथ कथानक' आदि रचनाओं में, अपभ्रंश भाषा में स्वयंभू रचित 'पउमचरिउ' में तो विभिन्न आधुनिक भारतीय भाषाओं में भी रामकथा रचना की समृद्ध परंपरा मिलती है। गुजराती भाषा में 'रावण मंदोदरी संवाद' (श्रीधर), 'राम बालचरित' (भालण), 'रामायण' (नाकर), उड़िया भाषा में 'जगमोहन रामायण' या 'दाण्डि रामायण' या 'ओड़िआ रामायण', तेलुगु भाषा में 'भास्कर रामायण', 'रंगनाथ रामायण', 'रघुनाथ रामायण', कन्नड भाषा में 'कुमुदेन्दु रामायण', 'तोरवे रामायण', असमिया में 'कथा रामायण', वंगला भाषा में 'कृत्तिवास रामायण', पंजाबी भाषा में 'रामावतार' या 'गोविन्द रामायण', कश्मीरी में 'रामावतार चरित', मलयालम में 'रामचरितम्', तमिल में 'कंबरामायण' की रचना हुई। हिन्दी में गोस्वामी तुलसीदास की 'रामचरित मानस' और 'विनय पत्रिका' के साथ उनकी अन्य रचनाएँ अलग-अलग भूमिकाओं में राम की एक अलग छवि उपस्थित करती हैं।

रामकथाओं पर गहन विचार-मन्थन कर विविध विद्वानों ने राम की अलग-अलग छवियाँ उपस्थित की हैं। कौसल्या के अपने राम हैं, वहीं कैकेयी और सुमित्रा के भी अपने राम हैं। दशरथ के राम एक विशेष पहचान रखते हैं तो सीता, लक्ष्मण और भरत के भी अपने राम हैं।

ये सभी और इन सभी के साथ सदा से ही भारतीय समाज राम को अलग-अलग रूपों में देखता आया है। राम कभी आदर्श पुत्र के रूप में दिखायी पड़ते हैं तो कभी एक आदर्श भाई के रूप में, कभी एक आदर्श पति के रूप में तो कभी एक आदर्श सखा के रूप में। इस प्रकार राम का स्वरूप बड़ा ही व्यापक और वैविध्यमय है।

गोस्वामी तुलसीदास ने रामकथा की महत्ता का बखान करते हुए लिखा है कि 'मंगल करनि कलिमल हरनि तुलसी कथा रघुनाथ की।' इस मंगलकारी कथा को राम और भरत के सन्दर्भ में देखें तो पाते हैं कि 'रामचरितमानस' में राम और भरत के प्रसंग अनेक स्थानों पर आये हैं और भरत अपने ज्येष्ठ भ्राता राम के प्रति पूरी तरह समर्पित और निष्ठावान् हैं। मानस के अयोध्याकाण्ड में अनेक प्रसंग ऐसे हैं जो भरत के हृदय में बसी राम की छवि का उद्घाटन करते हैं। रामकथा के प्रसिद्ध आलोचक योगेन्द्र प्रताप सिंह लिखते हैं कि "अयोध्याकाण्ड का उत्तरांश अर्थात् भरत कथा इस पूर्वांश से कहीं अधिक महत्तम, कर्म तथा ज्ञान से भिन्न मात्र भक्ति की ऐकांतिक प्रतिष्ठा से परिपूर्ण आराध्य के ध्यान में विगलित तुलसी जैसे पिपासु भक्तों के लिए मानक आदर्श के रूप में है। अयोध्याकाण्ड के इस उत्तरांश के कथानायक भरत हैं और ये भरत दशरथ पुत्र ही नहीं, राम के अनुज भी नहीं, भक्तप्रवर गोस्वामी तुलसीदास की प्रतिमूर्ति हैं।"[2] यहाँ यह स्पष्ट हो जाता है कि दशरथ और भरत के मन में राम की अलग-अलग छवियाँ हैं। भरत जी के प्रयाग जाने और भरत-भारद्वाज संवाद के प्रसंग में गोस्वामी तुलसीदास भरत हृदस्थ भावों की जो सुन्दर अभिव्यक्ति देते हैं, उससे हम भरत के राम का एक परिचय प्राप्त कर सकते हैं–

अरथ न धरम न काम रुचि गति न चहउँ निरवान।
जनम जनम रुति राम पद यह बरदानु न आन।।
जानहुँ राम कुटिल करि मोही। लोग कहउ गुर साहिब द्रोही।
सीता राम चरन रति मोरें। अनुदिन बढ़उ अनुग्रह तोरें।"[3]

यहाँ भरत अपनी इच्छा को दर्शाते हुए यह स्पष्ट कर देते हैं कि उन्हें राम के अतिरिक्त धर्म, अर्थ, काम और मोक्ष आदि किसी प्रकार की कामना नहीं है। साथ ही सीताराम के चरणों में उनके प्रेम की दिनोंदिन वृद्धि की कामना रखते हैं। ऋषि भारद्वाज अपने कथनों के माध्यम से यह स्पष्ट कह देते हैं कि भरत तुम्हारा यश निर्मल है और लोक तथा वेद दोनों तुम्हारे निर्मल यश का गान करेंगे। भरत की माता कैकेयी के कारण मिले राम-वनवास पर भरत आत्मग्लानि महसूस करते हैं और यह सोचते हैं कि राम के मन में उनके प्रति क्या चल रहा होगा। इस पर मुनि का कथन राम के उदार स्वरूप और भरत के प्रति उनके प्रेम को दर्शाता है। मानस के अयोध्याकाण्ड में कथन है–

सुनहु भरत रघुबर मन माहीं। पेम पात्रु तुम्ह सम कोउ नाहीं।।
लखन राम सीतहि अति प्रीती। निसि सब तुम्हहि सराहत बीती।।
जाना मरमु नहात प्रयागा। मगन होहिं तुम्हरे अनुरागा।।
तुम्ह पर अस सनेह रघुबर कें। सुख जीवन जग जस जड़ नर कें।।[4]

राम के वनगमन और दशरथ के निधन के बाद के प्रसंग जब शत्रुघ्न सहित भरत अयोध्या लौटते हैं तो वे प्रसंग बड़े कारुणिक बन पड़े हैं। भरत अपनी माता कैकेयी को जब इन सबका कारण मानते हैं तो वे अपनी माता को बहुत भला-बुरा कहते हैं और राम के प्रति अपने

अनुराग को दर्शाते हैं। अपनी माता को उनके कृत्य पर धिक्कारते हुए वे राम और अपने परिवार के प्रति अपने अनुराग को कुछ इस प्रकार दर्शाते हैं–

भरतहि बिसरेउ पितु मरन सुनत राम बन गौनु।
हेतु अपनपउ जानि जियँ थकित रहे धरि मौनु।।

जौं पै कुरुचि रही अति तोही। जनमत काहे न मारे मोही।।
पेड़ काटि तैं पालउ सींचा। मीन जिअन निति बारि उलीचा।।
हंसबंसु दसरथु जनकु राम लखन से भाइ।
जननी तूँ जननी भई बिधि सन कछु न बसाइ।।[5]

इस पश्चात्ताप और दुःख की घड़ी में भी राम की माता कौसल्या भरत पर अपना स्नेह दर्शाती हैं और उनके मन में भरत के प्रति उनके प्यार में किसी प्रकार की कमी नहीं आती है। भरत इन सब अनर्थों का कारण स्वयं को स्वीकारते हैं।

मातु भरत के बचन सुनि साँचे सरल सुभायँ।
कहति राम प्रिय तात तुम्ह सदा बचन मन कायँ।।
राम प्रानहु तें प्रान तुम्हारे। तुम्ह रघुपतिहि प्रानहु तें प्यारे।।
बिधु बिष चवै स्रवै हिमु आगी। होइ बारिचर बारि बिरागी।।
भएँ ग्यानु बरु मिटै न मोहू। तुम्ह रामहि प्रतिकूल न होहू।।
मत तुम्हार यहु जो जग कहहीं। सो सपनेहुँ सुख सुगति न लहहीं।।[6]

यहाँ उपर्युक्त कथनों के माध्यम से कौसल्या माता यह आश्वस्त करती है कि हे भरत, राम को तुम अपने प्राणों से भी अधिक प्यार करते हो। अतः अपने मन में इस प्रकार का विषाद न लाओ। चित्रकूट के मार्ग पर भरत बहुत व्याकुल होकर बढ़ रहे होते हैं। वे मार्ग में मिलने वाले प्रत्येक जन से सीता-राम और लक्ष्मण की कुशल और स्थान के बारे में पूछते हैं। भरत जी के भाईपने, भक्ति और आचरण की प्रत्येक व्यक्ति सराहना करता है। स्वयं गोस्वामी तुलसीदास ने भी लिखा है कि "भायप भगति भरत आचरनू। कहज सुनत दुःख दूषन हरनू।।" जब चित्रकूट में भरत के आगमन से पूर्व लक्ष्मण राम के समक्ष यह शंका व्यक्त करते हैं कि भरत को राजमद हो गया है तो राम अपने भाई भरत के आचरण और व्यवहार के विषय में लक्ष्मण को जो कहते हैं उससे राम और भरत के परस्पर स्नेह-सम्बन्ध का ज्ञान होता है। राम कहते हैं–

भरतहि होइ न राजमदु बिधि हरि हर पद पाइ।
कबहुँ कि काँजी सीकरनि छीरसिंधु बिनसाइ।।
तिमिरु तरुन तरनिहि मकु गिलई। गगनु मगन मकु मेघहिं मिलई।।
गोपद जल बूड़हिं घटजोनी। सहज छमा बरु छाड़ै छोनी।।
मसक फूँक मकु मेरु उड़ाई। होइ न नृपमदु भरतहि भाई।।
लखन तुम्हार सपथ पितु आना। सुचि सुबंधु नहिं भरत समाना।।[7]

भरत के चित्रकूट आगमन पर सबके मिलाप के पश्चात राम-भरत संवाद में भी हम भरत के राम का स्वरूप जान सकते हैं।

मैं जानउँ निज नाथ सुभाऊ। अपराधिहु पर कोह न काऊ।।
मो पर कृपा सनेहु बिसेषी। खेलत खुनिस न कबहूँ देखी।।
सिसुपन तें परिहरेउँ न संगू। कबहुँ न कीन्ह मोर मन भंगू।।
मैं प्रभु कृपा रीति जियँ जोही। हारेहूँ खेल जितावहिं मोही।।
महूँ सनेह सकोच बस सनमुख कही न बैन।
दरसन तृपित न आजु लगि प्रेम पिआसे नैन।।[8]

यहाँ भरत जी के कथन सम्पूर्ण सभा पर अपना प्रभाव छोड़ते हैं और एक आदर्श भाई का स्वरूप सभी को यहाँ दृष्टिगत होता है। राम भी उन्हें स्पष्ट रूप से समझाते हैं कि जीवन की गति हमारे वश में नहीं है, ये सब ईश्वराधीन हैं। वे राम को तीनों कालों और तीनों लोकों में श्रेष्ठ होने की संज्ञा देते हैं। भरत के राम के प्रति इसी प्रेम के विषय में प्रसिद्ध आलोचक योगेन्द्र प्रताप सिंह लिखते हैं कि "हिन्दी साहित्य के विवेचकों ने भरत की भक्ति को भायप भक्ति के रूप में स्वीकार किया है। उनके अनुसार भरत में अपने अग्रज के लोकात्मक सम्बन्ध का एक ओर निर्वाह है तो दूसरी ओर उनमें आराधक की भाँति समर्पण निष्ठा भी है। इस प्रकार लोक सम्बन्ध तथा भक्ति निष्ठा का निर्वाह दोनों तत्त्व भरत के चरित्र द्वारा निर्दिष्ट किये जा सकते हैं। लोक सम्बन्ध मूलतः प्रसंग में नगण्य है। कथा सन्दर्भ है कि वे श्रीराम के लघु भ्राता हैं। कवि भायप भक्ति में भायप अर्थात् भातृत्व का धीरे-धीरे विलयन उनके भक्त व्यक्तित्व में करता है। राम के लिए सर्वस्व त्याग, उनके दर्शन की महती उत्कण्ठा एवं हर्षातिरेक, वहाँ तक पहुँचने के लिए सम्पूर्ण संकटों का वरण, अपने सम्पूर्ण जीवन को आराध्य राम की प्रियता के अनुकूल परिवर्तित करने का भाव और उनके लिए अगाध मोह–ये ऐसे तत्त्व हैं, जो उन्हें भाई की अपेक्षा भक्त अधिक स्वीकार कराते हैं।"[9]

भरत को राजपाट से कुछ भी स्नेह नहीं है। वह तो राम का साथ चाहते हैं, इसी कारण वे स्पष्ट शब्दों में कह उठते हैं कि राजतिलक ग्रहण करने की सभी सामग्री साथ लाई गयी है, आप इसे स्वीकार करें और मैं स्वयं वन जाकर पिता को दिया गया आपका वचन पूरा करूँगा। तुलसी इस प्रसंग को इस प्रकार वर्णित करते हैं–

जो सेवकु साहिबहि सँकोची। निज हित चहइ तासु मति पोची।।
सेवक हित साहिब सेवकाई। करै सकल सुख लोभ बिहाई।।
स्वारथु नाथ फिरें सबही का। किएँ रजाइ कोटि बिधि नीका।।
यह स्वारथ परमारथ सारू। सकल सुकृत फल सुगति सिंगारू।।
देव एक बिनती सुनि मोरी। उचित होइ तस करब बहोरी।।
तिलक समाजु साजि सबु आना। करिअ सुफल प्रभु जौं मनु माना।।
सानुज पठइअ मोहि बन कीजिअ सबहि सनाथ।
नतरु फेरिअहिं बंधु दोउ नाथ चलौं मैं साथ।।[10]

जनक-सुनयना संवाद में गोस्वामी जी ने भरत के गुणों और चरित्र का जो बखान किया है, वह अनुपम है। वे भरत को भरत के समान ही बताते हैं, उनकी दृष्टि में भरत के लिए कोई दूसरी उपमा उचित ही नहीं है। वे कहते हैं कि जैसे मछली का पृथ्वी पर विचरण असम्भव है वैसे ही भरत की महिमा का बखान असम्भव है। तुलसीदास जी लिखते हैं कि **"निरवधि गुन निरुपम पुरुषु भरतु भरत सम जानि। कहिअ सुमेरु कि सेर सम कबिकुल मति सकुचानि।।"**[11] राम के साथ संवाद करते समय भरत राम के शरणागत वत्सल स्वरूप का उद्घाटन करते हैं। अयोध्याकाण्ड की उत्तर कथा में हम इस प्रसंग के चरमबिन्दु को देख सकते हैं, जहाँ एक भाई के मन में वनगमन को लेकर कोई खेद नहीं है तो दूसरा भाई इतने बड़े राजपाट के मोह से बिल्कुल दूर है। एक आदर्श स्वरूप की रचना समाज को एक विशिष्ट सन्देश देती है। भरत का राम के साथ संवाद सुनकर उपस्थित साधुओं का समाज और अन्य परिवारजन सभी भरत जी की प्रशंसा करते नहीं थकते हैं।

रघुराउ सिथिल सनेहँ साधु समाज मुनि मिथिला धनी।
मन महुँ सराहत भरत भायप भगति की महिमा घनी।।
भरतहि प्रसंसत बिबुध बरषत सुमन मानस मलिन से।
तुलसी बिकल सब लोग सुनि सकुचे निसागम नलिन से।।[12]

राम और भरत के मिलन के विषय में योगेन्द्र प्रताप सिंह का कथन है कि "श्रीराम और भरत का यह सम्मिलन अयोध्याकाण्ड की कथा का कथाफल है। भरत की मानसिक संसक्ति एवं वासना के रूप में राम के वियोग की पीड़ा का मार्मिक चित्रांकन करके उसे भातृत्व वियोग से कहीं अधिक आराध्य राम के लिए भक्त की निरन्तर छटपटाहट के रूप में चित्रित करने के लिए कवि प्रयत्नशील है। एक योगी जिस प्रकार परासमाधि दशा में केवलाद्वैत भाव में प्रतिष्ठित रहता है, ब्रह्म के बिम्ब से प्रतिविम्बित उसका चित्त समाधि दशा में शून्य एवं जड़वत् हो उठता है वैसी ही दशा भरत एवं श्रीराम के गूढ़ स्नेह सम्मिलन की है।"[13]

राम की चरण पादुकाओं को ग्रहण कर अयोध्या लौटना और नन्दीग्राम में पर्णकुटी बनाकर उसमें निवास करते हुए रामाज्ञा मानते हुए राम के अयोध्या लौटने तक शासन सँभालने में भी भरत का व्यक्तित्व अधिक ऊँचाई ग्रहण करता है। राम के प्रति अगाध प्रेम के कारण ही भरत मुनि वेश ग्रहण कर उसी प्रकार का जीवन स्वीकार कर लेते हैं जिस प्रकार वनवासी राम का जीवन था। वे सिर पर जटा, वदन पर वल्कल वस्त्र धारण कर लेते हैं। वे भोजन, वस्त्र, व्रत और नियम आदि के पालन में ऋषियों की दिनचर्या को अपना कर राम के प्रति अपने एकनिष्ठ प्रेम को दर्शाते हैं। तुलसी लिखते हैं–

जटाजूट सिर मुनिपट धारी। महि खनि कुस साँथरी सँवारी।।
असन बसन बासन ब्रत नेमा। करत कठिन रिषिधरम सप्रेमा।।
भूषन बसन भोग सुख भूरी। मन तन बचन तजे तिन तूरी।।
अवध राजु सुर राजु सिहाई। दसरथ धनु सुनि धनदु लजाई।।
तेहिं पुर बसत भरत बिनु रागा। चंचरीक जिमि चंपक बागा।।
रमा बिलासु राम अनुरागी। तजत बमन जिमि जन बड़भागी।।[14]

लक्ष्मण मूर्च्छा के प्रसंग में हनुमान जी का संजीवनी लेकर लौटते समय भरत के बाण से आहत होने के प्रसंग में गोस्वामी जी ने भरत का अपने भाइयों के प्रति प्रेमभाव वर्णित किया है। हनुमान जी के मुख से रामनाम का उच्चारण सुनकर उन्हें भरत जी गले लगाते हैं और अपने किये पर पश्चात्ताप व्यक्त करते हैं। उन्हें यहाँ भी लगता है कि देव उनकी कठिन परीक्षा ले रहे हैं।

जेहिं बिधि राम बिमुख मोहि कीन्हा। तेहिं पुनि यह दारुन दुःख दीन्हा।।
जौं मोरें मन बच अरु काया। प्रीति राम पद कमल अमाया।।[15]

लंकाकाण्ड के उस प्रसंग में जब राम वनवास अवधि बीत जाने पर अयोध्या वापसी का कहते हैं तब वे विभीषण से अपने भाई भरत के विषय में जो कहते हैं उससे भरत के प्रति उनके अगाध प्रेम की अभिव्यक्ति मिलती है। तुलसीदास जी इस प्रसंग को इस प्रकार वर्णित करते हैं–

तोर कोस गृह मोर सब सत्य बचन सुनु भ्रात।
भरत दसा सुमिरत मोहि निमिष कल्प सम जात।।
तापस बेष गात कृस जपत निरन्तर मोहि।
देखौं बेगि सो जतनु करु सखा निहोरउँ तोहि।।
बीतें अवधि जाउँ जौं जिअत न पावउँ बीर।
सुमिरत अनुज प्रीति प्रभु पुनि पुनि पुलक सरीर।।[16]

राम को यहाँ स्पष्ट स्मरण है कि अवधि बीत जाने पर उन्हें तुरन्त अयोध्या पहुँचना है क्योंकि भरत वहाँ राम का वेसब्री से इन्तजार कर रहे हैं। अब राम का हर क्षण भरत के बिना एक कल्प के समान लग रहा है। यह इस बात को दर्शाता है कि जितना स्नेह भरत के हृदय में राम के प्रति है उतना ही स्नेह हमें राम के हृदय में भी भरत के प्रति दृष्टिगत होता है। उत्तरकाण्ड के प्रसंग में जब राम के वनवास की अवधि मात्र एक ही दिन शेष रह जाती है तब भरत के मन में पुनः शंका उठने के प्रसंगों का वर्णन गोस्वामी जी ने किया है। यहाँ यह भाव सहज ही द्रष्टव्य होता है कि जिनमें अटूट प्रेम होता है, वहाँ मन में कई बार विपरीत भाव भी संचरित हो जाते हैं। शायद इसी कारण भरत के मन में यह भाव आने लगा कि अवधि पूर्ण होने को है और राम के आगमन का समाचार नहीं मिला, कहीं राम ने मुझे भुला तो नहीं दिया। यहाँ भी राम के प्रति भरत का प्रेम दिखायी पड़ता है। गोस्वामी जी ने लिखा है–

रहेउ एक दिन अवधि अधारा। समुझत मन दुःख भयउ अपारा।।
कारन कवन नाथ नहिं आयउ। जानि कुटिल किधौं मोहि बिसरायउ।।
अहह धन्य लछिमन बड़भागी। राम पदारबिन्दु अनुरागी।।
कपटी कुटिल मोहि प्रभु चीन्हा। ताते नाथ संग नहिं लीन्हा।।
जौं करनी समुझै प्रभु मोरी। नहिं निस्तार कलप सत कोरी।।
जन अवगुन प्रभु मान न काऊ। दीन बन्धु अति मृदुल सुभाऊ।।[17]

स्वयं राम भी जब भरत से मिलते हैं तो हनुमान जी को सम्बोधित करते हुए यह बात स्पष्ट कर देते हैं कि "तुम्हु जानहु कपि मोर सुभाऊ। भरतहि मोहि कछु अन्तर काऊ।"[18] यह सब राम के हृदय की उदारता को दर्शाता है कि राम वनवास की लम्बी अवधि व्यतीत कर लौटे हैं,

किन्तु अपने भाई के प्रति उनके मन में कोई दुर्भाव नहीं अपितु और स्नेह संचरित है। अपनी इस रचना और विशेष रूप से अयोध्याकाण्ड की कथा नवधा भक्ति में भायप भक्ति को और जोड़ती है। भरत के माध्यम से तुलसीदास जी ने अपने हृदय के भक्तिभावों को सुन्दर अभिव्यक्ति दी है। भरत के माध्यम से गोस्वामी जी ने मध्यकालीन भक्ति के विशेष स्वरूप को रचा है जिसमें आराध्य आराधक से सम्पूर्णता से जुड़ता है। जिस प्रकार भरत चातक की भाँति अपने आराध्य राम के प्रति एकनिष्ठ हैं वैसे ही तुलसीदास जी ने भी अपने भटकाव को राम में केंद्रित कर स्थिरता दी है। वे अपनी रचना दोहावली में लिखते हैं–

एक भरोसो एक बल एक आस विश्वास।
एक राम घनस्याम हित चातक तुलसीदास।।[19]

ABSTRACT: Scientometrics is a branch of library Science which is used for analysing and calculating different parameters which specify researcher's quantitative research output. This study examines scientometric analysis on *Syzygium aromaticum* (Medicinal Plant) of Global Publications Output during 2011-2021. By measuring and analysing the distribution of articles, year-wise, annual growth rate, authorship pattern, author productivity, relative growth rates, doubling time, degree of collaboration, ranked list of authors, Collaborative Co-efficient and Modified Collaborative Co-efficient during this period. In this period of 11 years only 1569 publications were found. Publication of research in this field was steady and didn't was too productive. In the year 2017 has the highest and positive AGR (40.00 %). The total number of publications is 1569, in which 56 single author publications and all others are multiauthored. In years 2018 and 2020, the AAPP of publications as well as authors are highest and APA is lowest. The degree of collaboration, in 2018 is maximum (0.98).The Collaborative Co-efficient and MCC was 0.756 and 0.757 successively. After analysing above parameters it has been concluded that research work on this field, require further research.

KEYWORDS: *Syzygium aromaticum*, Relative Growth Rate, Authorship pattern. Coefficient Collaboration, Modified Coefficient Collaboration, Medicinal plant

1. Introduction

Medicinal plants have multifunctional applications and in this series *Syzygium aromaticum* (Medicinal Plant) (clove)has widely used in treatment of various diseases. Traditional Medicine are using by the all classes of people. Herbal medicinal products play a significant role for discovering new pharmaceutical molecules to treat serious diseases. According to El-SaberBatihaetal, (2020) "*Syzygium aromaticum*is have various pathogenic parasites and microorganisms, including pathogenic bacteria, Plasmodium, Babesia, Theileria parasites, Herpes simplex, and hepatitis C viruses. Several reports documented the analgesic, antioxidant, anticancer, antiseptic, anti-depressant, antispasmodic, anti-inflammatory, antiviral, antifungal, and antibacterial activity of eugenol against

several pathogenic bacteria including methicillin-resistant *Staphylococcus epidermidis* and *S. Aureus".*

Syzygium aromaticum (clove) is a traditional spice that has been used for food preservation and possesses various pharmacological activities. *Syzygium aromaticum* (clove) is an ingredient which has been employed for centuries as food preservative and various medicinal purposes including its antimicrobial and antioxidant properties (Kumar et al., 2021).

Scientometricsis a part of Library and Information Science in which data of researchers is collected and analysed with the help of scientometric tools. Merton and Garfield,1963 stated that scientometric as 'the field of enquiry given over to the quantitative analysis of science and scientific field'. According to the Glossary of Thompson Scientific Terminology, scientometric is the quantitative study of the disciplines of science based on published literature and communication.

2. Review of Literature

Literature review covers an assessment of works related to several aspects of Scientometric studies. Literature in any field always has an important role towards identification, formalization of research problem and orients the researcher to carry further research in a right direction with clear perception.

Sivasekaran (2021) assessed scientometrics on the Global Publication output on *Curcuma Longa* (Medicinal plant). The study covers 6087records of 2000 to 2019 with reference to Web of Science data. Global citation score distribution of publications by Journals, h- Index and citation profile are analysed. India is at top position followed by USA,China and Iran are contributing in this field. The Journal 'Food Chemistry' is at top in this field. In 2019 maximum research articles were published and lowest in 2001. Total 24 Journals contributed 13.49 percent contributions and they had 16.01 percent Citations.

Tabatabaei-Malazy et al. (2016) assessed scientometric analysis of research efficiency in pasture of Ant oxidative hypoglycaemic herbal medicine on diabetes. 468 documents were downloaded from Scopus database till 2015 related to human. Using VOS Viewer and SPSS the data was analyzed. US is the top most contributing county in this research

Massarrat & Kolahdoozan (2011) studied the contributions of the Iranand Turkey on medical journals which were indexed by WOS from 2007 to 2010. Six citations by the author and IF on the clinical research published from 60 international journals were contributions by the Iran and Turkey. 21 journals

from Iranian were indexed with ISI. Turkey,4,876 articles were published with 1,331 citations per author noticed. The average citations of the foreign authors per authors noticed that 0.19 was from Iranian researchers and 0.3 was gained by the Turkish researchers. Turkey had produced more articles, citations and citations per authors on international collaborations.

Ali & Kumari (2018) conducted a scientometric study on the biodiversity publications from 1989 to 2016. A total 1,54,654 records retrieved from WOS. BibExcel and MSExcel. Gastone, KJ is the most prolific author in biodiversity research with 257 publications. 90% of the article contributed buy multi-authors. Among the institutional contributions, Chinese Academy of Sciences got ranked first with 2,305 publications. It is identified 15.6% of the Articles did not receive any citations on biodiversity research.

Gupta et al. (2016) examined a study on the research contributions on Migraine,from the period 2006-2915 from Scopus. The study noticed that 9.80% was international collaboration 18 and 2.56 as share of global level publications. 75.3% of the publications was contributed by top most 10 countries. Numerous journals published the migraine research from Indian, among them top most 15 journals was rated as one third. The citation per article was rated as 149.57 among 1087 citations. The study concluded with requirement of national level policy to undertake the R&D policy for improving the migraine research for the common cause.

3. Objectives of the Study

This study has the following objectives:

1. To study year -wise distribution of the articles published during 2011 to 2021.
2. To find annual growth rate of Publications.
3. To reveal authorship pattern and author productivity.
4. To examine Relative Growth Rates and Doubling Time of Publications.
5. To recognize Degree of collaboration, Co-authorship and Collaboration Index.
6. To recognize Collaborative co-efficient and Modified co-efficient.
7. To study country wise distribution of publications.

4. Research Methodology

The required data was collected from Scopus database for the period 2011 to2021. It can be seen that 1569 research publication retrieved from this database on *Syzygium aromaticum* medicinal plant. The researcher downloads data and then further analysed the data with the help of MS Excel software as per the objectives ofthe study. The aim of the study to tabulate and to analyse thrust areas of *Syzygium aromaticum* medicinal plant.

5. Result and Discussions

5.1 (a) Year-Wise Distribution of Publications

Table 1: Year-Wise Distribution of Publications & Annual Growth Rate

S. No.	Year	No. of Publications	%	Cumulative No. of Publications	AGR (%)
1	2011	163	10.38	163	-
2	2012	158	10.07	321	-3.06
3	2013	125	7.96	446	-20.88
4	2014	126	8.03	572	0.80
5	2015	128	8.17	700	1.58
6	2016	98	6.24	798	-23.00
7	2017	138	8.79	1036	40.00
8	2018	117	7.45	1053	-15.21
9	2019	159	10.14	1212	26.41
10	2020	174	11.08	1386	8.62
11	2021	183	11.66	1569	6.32
Total		1569	100		

Table-1 shows total 1569 publications have been published in these eleven years. Maximum 183 publications are published in 2021. On this plant research was steady and shows oscillatory trends in this period of eleven years' publications becomes 183 from 163.

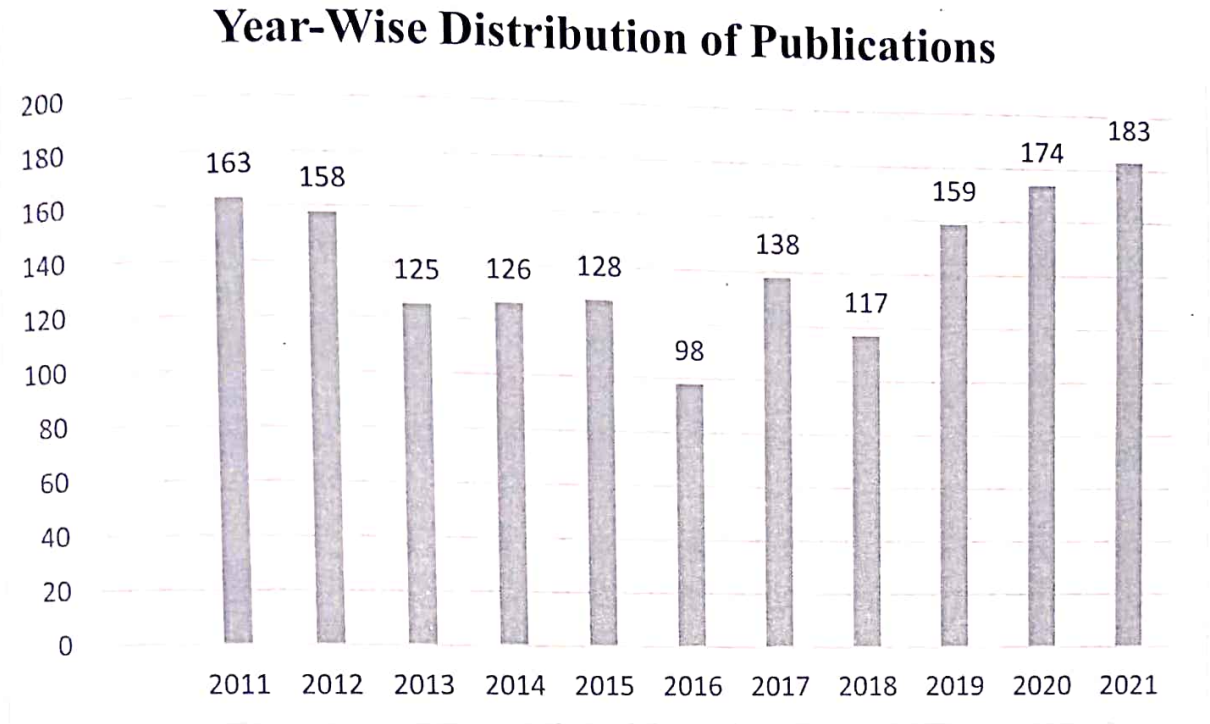

Fig. 1: Year-Wise Distribution of Articles

The year-wise distribution of Articles is displayed in Figure-1. The Figure is drawn between two parameters *No. of Articles* and *Year-wise growth* and shows the growth of Articles with respect to the Year. It is clear from the Figure that in 2021 maximum number of articles were published.

5.1 (b) Annual Growth Rate

The *Annual Growth Rate* (AGR) reflects the rate of growth over a single year.

$$\text{Annual Growth Rate} = \frac{(\text{Suceeding Value} - \text{Previous Value})}{\text{Previous Value}}$$

The following Figure-2 demonstrates the growth of publications with AGR. From this figure, it is observed that the year 2017 has the highest and positive AGR (40.00 %) among others. The year 2012, 2013, 2016 and 2018 have negative AGR (in %).

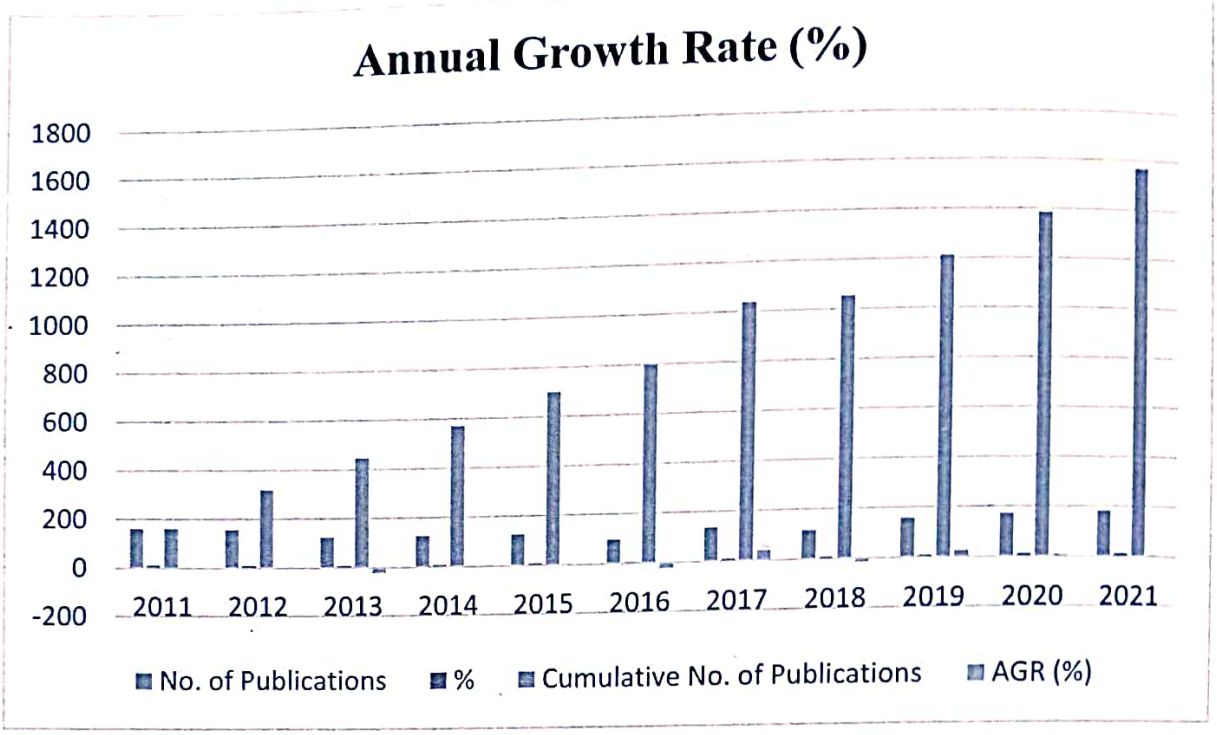

Fig. 2: Annual Growth Rate

5.2 Authorship Pattern

Table 2: Authorship Pattern

Year	Single Author	Two Authors	Three Authors	Four Authors	Five Authors	Six Authors	More than Six Authors	No. of Publications
2011	8	27	36	26	25	15	26	**163**
2012	5	28	36	32	21	19	17	**158**
2013	5	24	31	17	20	11	17	**125**
2014	8	13	21	25	27	9	23	**126**
2015	6	23	22	30	19	11	17	**128**
2016	3	13	15	23	20	10	14	**98**
2017	4	12	21	27	24	19	31	**138**
2018	2	12	13	31	16	20	23	**117**
2019	6	16	25	29	28	20	35	**159**
2020	4	9	30	37	25	23	46	**174**
2021	5	16	29	37	34	22	40	**183**
Total	56	**193**	**279**	**314**	**259**	**179**	**289**	**1569**
%	**3.56**	**12.30**	**17.78**	**20.01**	**16.50**	**11.40**	**18.41**	**100**

Table - 2 describes the authorship pattern of articles during the period 2011 to 2021.The total number of publications are 1569, in which 56 single author publications, 193 two authors publications, 279 three authors publications, 314 four authors publications, and so on. It shows that article publication trend was towards the multiple author approach.

The following Figure -3 demonstrates the authorship pattern between the No. of publication and years. From this figure, it is found that the category of four authors has the largest community that is 20.01%.

Fig. 3: Authorship Pattern

5.3 Author Productivity

Table 3: Author Productivity

Year	Number of Authors	Number of Publications	APA	AAPP
2011	204	163	0.79	1.26
2012	250	158	0.63	1.58
2013	175	125	0.71	1.40
2014	285	126	0.44	2.27
2015	363	128	0.35	2.85
2016	368	98	0.26	3.84
2017	399	138	0.34	2.94
2018	558	117	0.20	5.00

Year	Number of Authors	Number of Publications	APA	AAPP
2019	611	159	0.26	3.84
2020	859	174	0.20	5.00
2021	805	183	0.22	4.54
Total	7346	1569	0.21	4.76

Table 3 reveals the data which deals with author productivity.1569 publications are retrieved. The *Productivity per author* and *Average Authors Per Paper* are calculated by the following formulae

$$\text{Productivity per author} = \frac{\text{Number of Articles}}{\text{Number of Authors}} = 0.238 = 0.21$$

The *Productivity per author*is less than one which means on an average *Productivity per author* is only **21%**.

$$\text{Average Authors Per Paper} = \frac{\text{Number of Authors}}{\text{Number of Articles}} = \mathbf{4.76}$$

The *average number of authors per paper (publication)* is obtained by dividing the total number of publicationsby the total number of authors. This may be a very useful indicator for determining a journal's or author's average effect.

The following figure represents the year wise production between the no. of publication no. of authors, Productivity per author and average author per paper. From the Figure 4, it is clear that in years2018 and 2020, the AAPP of publicationsas well as authors are highest and APA is lowest.

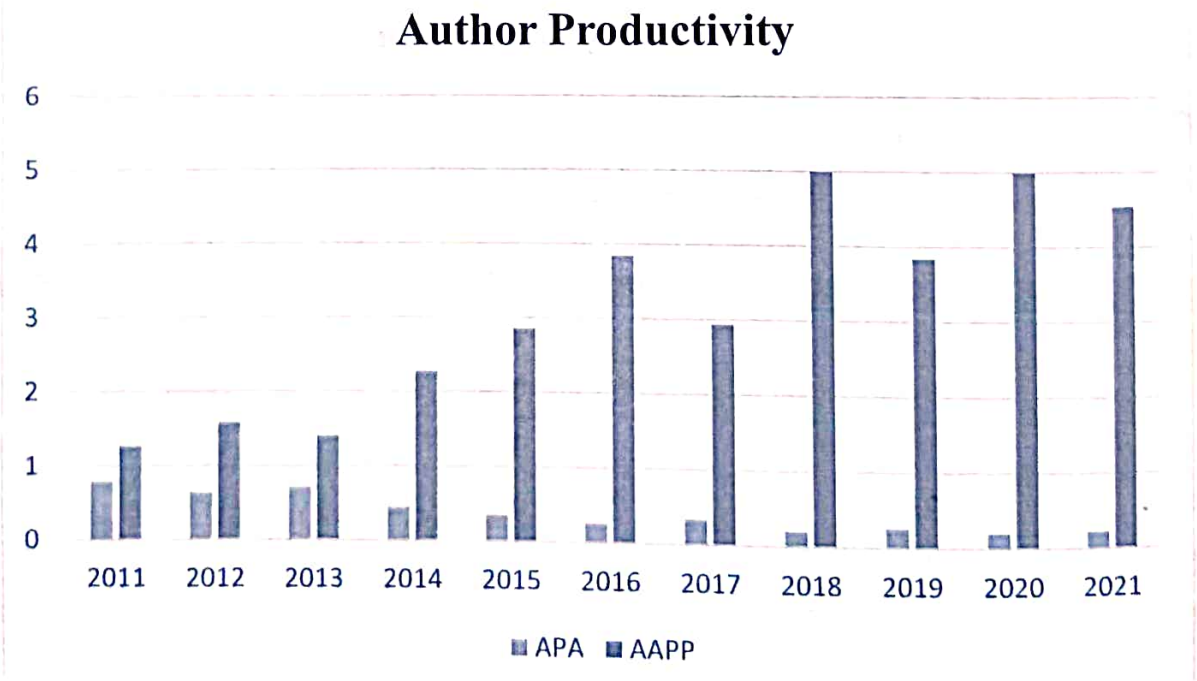

Fig. 4: Author Productivity

5.4 Relative Growth Rate of Publications & Doubling Time

Relative Growth Rate (RGR) is a measure to study the growth of number of articles over the period whereas Doubling Time (DT) is defined as the time when records become doubles values. The *Relative Growth Rate of Publications and Doubling Time* statics are mentioned in the following Table 4.

Table 4: Relative Growth Rate of Publications& Doubling Time

S. No	Year	No. of Publications	Cumulative Total	$LogW_1$	$LogW_2$	RGR	Doubling Time (DT=0.693/ RGR)	Mean RGR = ΣR/N	Mean ΣDt/N
1	2011	163	163	2.21	2.21	-	-		
2	2012	158	321	2.19	2.50	0.31	2.23		
3	2013	125	446	2.09	2.64	0.55	1.26		
4	2014	126	572	2.10	2.75	0.65	1.06		
5	2015	128	700	2.10	2.84	0.74	0.93	**0.710**	**0.908**
6	2016	98	798	1.99	2.90	0.91	0.76		
7	2017	138	1036	2.13	3.01	0.88	0.78		
8	2018	117	1053	2.06	3.02	0.96	0.72		
9	2019	159	1212	2.20	3.08	0.78	0.88		
10	2020	174	1386	2.24	3.14	0.90	0.77		
11	2021	183	1569	2.26	3.19	1.14	0.60		
Total		**1569**				**7.82**	**9.99**		

The RGR and DT model developed by Mahapatra (1985) and calculated by the following formula.

$$RGR = \frac{\log W_1 - \log W_1}{(T_2 - T_1)} = \mathbf{0.710}$$

where, T_1 and T_2 represent initial and final Time, respectively. $T_2 - T_1$ shows the time interval.

$$\text{Doubling Time} = \frac{0.693}{R} = \mathbf{0.908}$$

The following Figure 5 represents the graph of RGR and DT.

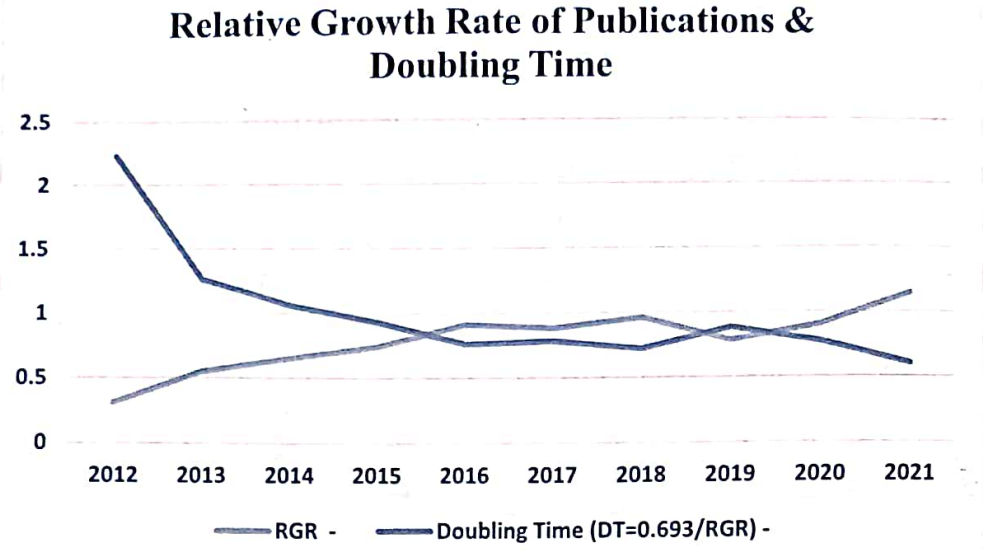

Fig. 5: AGR Growth and DT of Articles

5.5 Degree of Collaboration

The degree of collaboration is defined as the ratio of collaborative research publications to total research papers in the subject during a certain time period. Subramanyam (1983) proposed a formula for the degree of collaboration.

$$\text{Degree of Collaboration (DC)} = \frac{N_m}{(N_m + N_s)}$$

Where C represents the degree of collaboration. N_m and N_s represent the Multiple Author Publications and Single Author Publications respectively.

The Table 5 figures out the degree of collaboration. From this table, it is observed that in 2018 degree of collaboration is maximum (0.98). in years 2017, 2020 and 2021 have the 0.97 degree of collaboration. This implies that multiple authors contributed more than single authors.

Table 5: Degree of Collaboration

Year	Single Author Publications (Ns)	Multiple Author Publications (Nm)	Nm+Ns	Degree of Collaboration DC=Nm/(Nm+Ns)
2011	8	155	163	0.95
2012	5	153	158	0.96
2013	5	120	125	0.96
2014	8	118	126	0.93
2015	6	122	128	0.95

Year	Single Author Publications (Ns)	Multiple Author Publications (Nm)	Nm+Ns	Degree of Collaboration DC=Nm/(Nm+Ns)
2016	3	95	98	0.96
2017	4	134	138	0.97
2018	2	115	117	0.98
2019	6	153	159	0.96
2020	4	170	174	0.97
2021	5	178	183	0.97
Total	**56**	**1513**	**1569**	**0.964**

The following Figure 6 represents the graph of Degree of Collaboration.

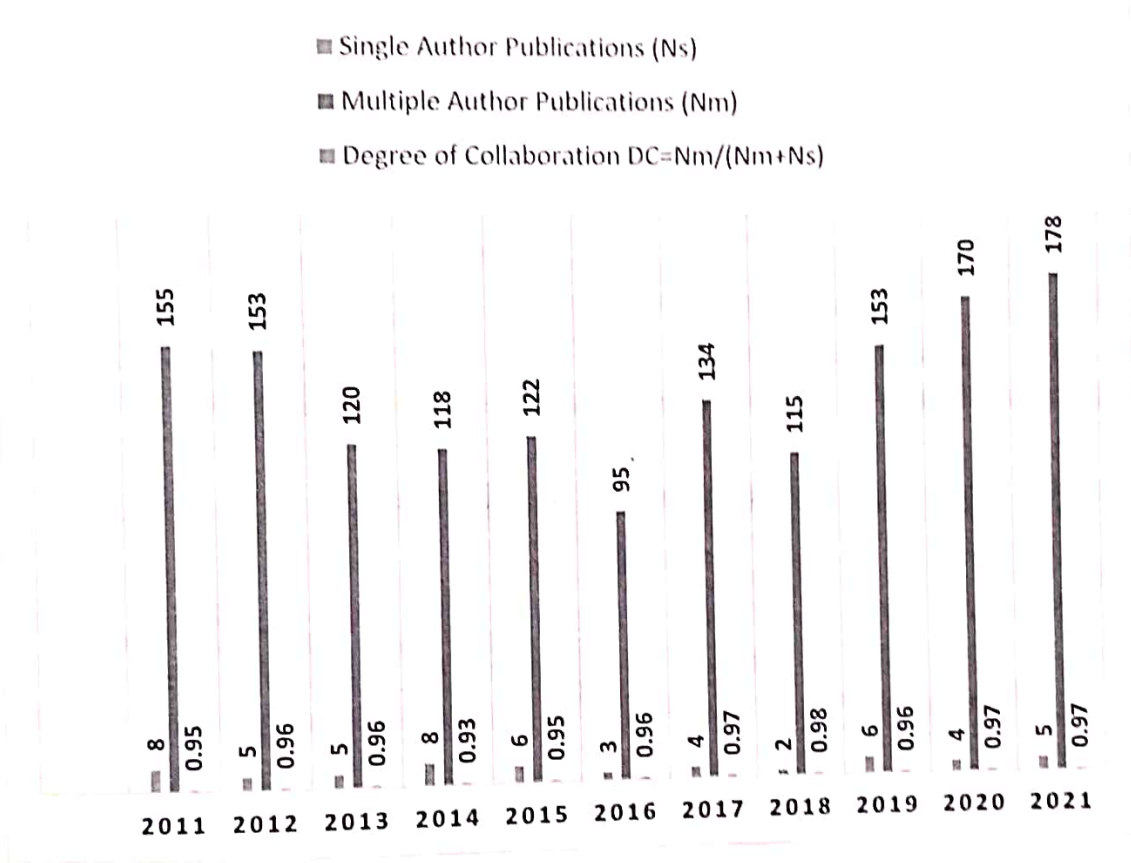

Fig 6: Degree of Collaboration

5.6 Collaborative Index (CI)

This index means number of authors per paper. To calculated collaborative Index formula is given by Elango and Rajendran.

$$CI = \frac{\text{Number of Authors}}{\text{Number of Joint Papers}}$$

Table 6: Collaborative Index (CI)

Years	Multi-author Papers	Total Authors of Multi-author Papers	Collaborative Index
2011	155	688	4.43
2012	153	645	4.21
2013	120	523	4.35
2014	118	568	4.81
2015	122	533	4.36
2016	95	431	4.53
2017	134	689	5.14
2018	115	583	5.08
2019	153	785	5.13
2020	170	928	5.45
2021	178	917	5.15
Total	**1513**	**7290**	**4.81**

Table 6 and figure 7 provide the year wise mean number of authors per joint authored paper. CI ranges from 4.43 (2011) to 5.15 (2021) were recorded, the highest CI (5.45) was recorded in 2020 and average CI was 4.81 for per Joint authored paper which indicates the researcher team trip between 4 and 6.

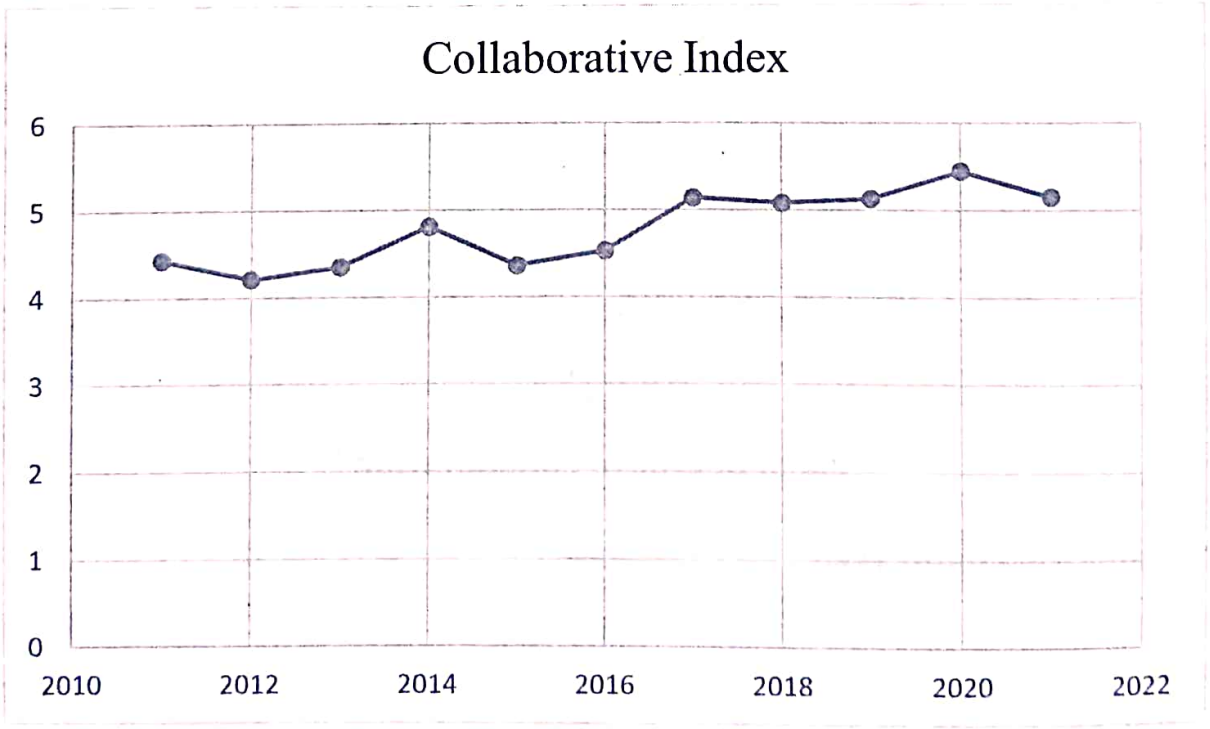

Fig. 7: Collaborative Index (CI)

5.7 Collaboration Coefficient and Modified Collaboration Coefficient

Ajiferuke, Burell and Tague have shown the mean number of authors per publications. According to them the part of multi authorship, as measures of degree of collaboration in a discipline, is inadequate. In this way; they proposed a measure combining some of the benefits of both measures into a term known as Collaborative Coefficient (CC).

The formula for Collaborative Coefficient (CC) is given by Ajiferuke et.al.

$$CC = 1 - \frac{1}{N}\sum_{j=1}^{k}\frac{1}{j}f(j)$$

Where,

fj= number of j-authors research publications published in a discipline during a certain period.

N = total number of research papers published in a discipline during a certain period

k = greatest number of authors per paper in a discipline.

$$\text{Calculation of Collaborative Coefficent} = 1 - \frac{f(1) + \frac{1}{2}f(2) + \frac{1}{3}f(3) + \frac{1}{4}f(4) + \cdots \frac{1}{n}f(n)}{N}$$

Based on the data in table 7Collaborative Coefficient for the year 2019 has been calculated as

$$CC = 1 - \frac{8 + \frac{1}{2}(27) + \frac{1}{3}(36) + \frac{1}{4}(26) + \frac{1}{5}(25) + \frac{1}{6}(15) + \frac{1}{7}(13) + \frac{1}{8}(18) + \frac{1}{9}(2) + \frac{1}{11}(2) + \frac{1}{12}(1)}{163}$$

$$CC = 1 - \frac{50.83}{163}$$

$$CC = 0.689$$

Similarly, all the data for CC calculated by this formula.

Modified collaboration coefficient (MCC)

The formula for calculation of MCC is given by Sarvanur and Srikanth.

$$MCC = \frac{A}{A-1}\{1 - \frac{1}{N}\sum_{j=1}^{k}\frac{1}{j}f(j)\}$$

$$MCC = 1 - \frac{8 + \frac{1}{2}(27) + \frac{1}{3}(36) + \frac{1}{4}(26) + \frac{1}{5}(25) + \frac{1}{6}(15) + \frac{1}{7}(13) + \frac{1}{8}(18) + \frac{1}{9}(2) + \frac{1}{11}(2) + \frac{1}{12}(1)}{163}$$

$$MCC = \frac{163}{162} X\ 0.689$$

MCC = 1.006 X 0.689 = 0.693

Similarly, the value of MCC for all the years can be calculated by using above formula.

Table 7: Collaboration Coefficient and Modified Collaboration Coefficient

Year	Single Authors	Two Authors	Three Authors	Four Authors	Five Authors	Six Authors	More than Six Authors	Total	CC	MCC
2011	8	27	36	26	25	15	26	163	0.689	0.693
2012	5	28	36	32	21	19	17	158	0.693	0.697
2013	5	24	31	17	20	11	17	125	0.687	0.691
2014	8	13	21	25	27	9	23	126	0.698	0.699
2015	6	23	22	30	19	11	17	128	0.688	0.689
2016	3	13	15	23	20	10	14	98	0.718	0.719
2017	4	12	21	27	24	19	31	138	0.750	0.751
2018	2	12	13	31	16	20	23	117	0.733	0.734
2019	6	16	25	29	28	20	35	159	0.741	0.742
2020	4	9	30	37	25	23	46	174	0.756	0.757
2021	5	16	29	37	34	22	40	183	0.745	0.746
Total	**56**	**193**	**279**	**314**	**259**	**179**	**289**	**1569**	**0.785**	**0.786**

Table 7 and figure 8 shows the Collaboration coefficient and Modified collaboration coefficient from the study. Highest CC and MCC was 0.756 and 0.757 successively listed in the year 2020. The total Collaboration coefficient (CC) was 0.785 and Modified collaboration coefficient (MCC) was 0.786.

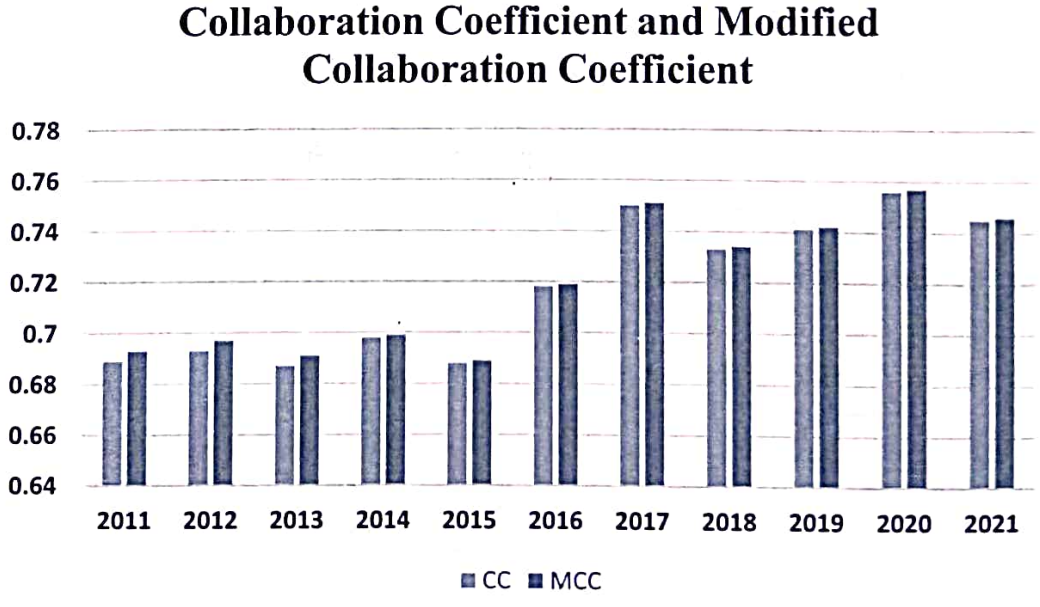

Fig. 8:Collaboration Coefficient and Modified Collaboration Coefficient

5.8 Countries–Wise Distribution of Articles (Top 10)

Table 8 and figure 9 shows displays the country-wise contribution of 1569 publication from different countries. It is found that the highest number of publications are from India (304), followed by the Brazil (167), China (100), Egypt (96), Indonesia (91), Iran (90), and so on.

Table 7: Country-Wise Distribution of Articles (Top 10)

Rank	Name of Country	Number of Publications
1	India	304
2	Brazil	167
3	China	100
4	Egypt	96
5	Indonesia	91
6	Iran	90
7	United States	85
8	Saudi Arabia	64
9	Thailand	64
10	Pakistan	59

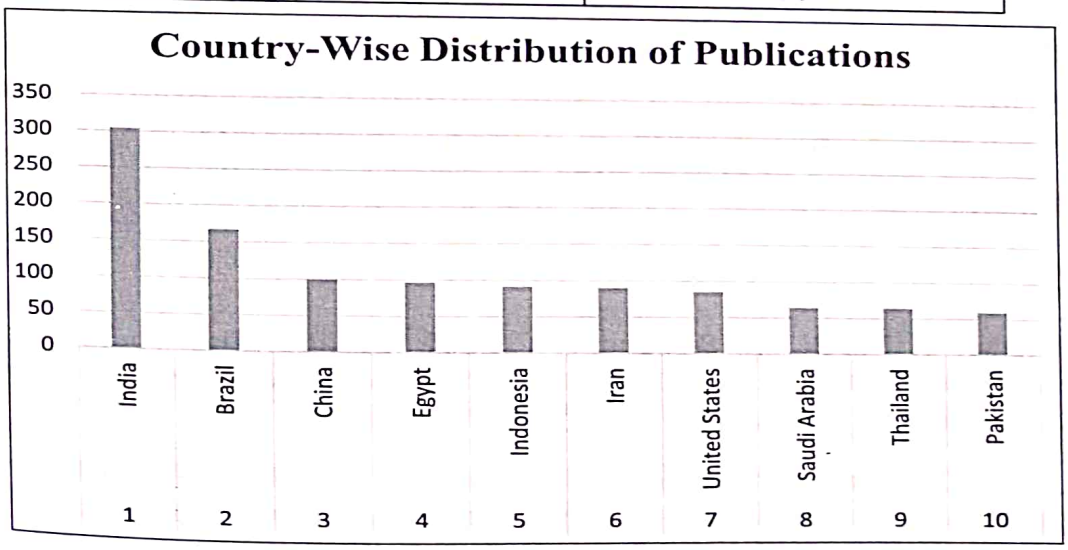

Fig. 9: Country-Wise Distribution of Publications

6. Findings and Conclusions

For studying ***Syzygium aromaticum*** **(Medicinal Plant) have 1569 publications** from the year of 2011 to 2021 using the Scopus database were retrieved. We have

examined such articles based on different scientometric parameters and their tools. We have demonstrated and discussed the observation using different Tables and Figure. The summary of the results are as follows.

- It has been found that in year 2020 maximum no. of articles 183 were published
- The total number of publications are 1569, in which 56 single author publications, 193 two authors publications, 279 three authors publications, 314 four authors publications, and so on. It shows that article publication trend was towards the multiple author approach.
- The *Productivity per author* and *Average Authors Per Paper* are 0.238 and 4.20.
- Relative Growth Rate (RGR) of publication of articles related to this field is 0.710 and average of Doubling time is 0.908.
- CI ranges from 4.43 (2011) to 5.15 (2021) were recorded, the highest CI (5.45) was recorded in 2020 and average CI was 4.81 for per Joint authored paper which indicates the researcher team trip between 4 and 6.
- The total Collaboration coefficient (CC) was 0.785 and Modified collaboration coefficient (MCC) was 0.786.
- It is found that the highest number of publications are from India (304), followed by the Brazil (167), China (100), Egypt (96), Indonesia (91), Iran (90), and so on.

विषयानुक्रमणिका

क्र.	विषय	पृ.क्र.
1.	भारतीय भाषाओं के विकास में प्राकृत का योगदान - डॉ ज्योति बाबू जैन	29
2.	प्राकृत भाषा महत्त्व एवं आधुनिक युग में इसके अध्ययन अध्यापन की दशा और दिशा - प्रो. फूलचंद जैन प्रेमी	39
3.	वैदिक संस्कृत पर प्राकृत प्रभाव - प्रो. दामोदर शास्त्री	51
4.	प्राकृत और संस्कृत का तुलनात्मक विवेचन -प्रो सुदर्शन लाल जैन	59
5.	प्राकृत अपभ्रंश एवं अन्य भारतीय भाषाएँ -प्रो. प्रेम सुमन जैन	70
6.	प्राकृत एवं बौद्ध संस्कृत - प्रो. विजय कुमार जैन	86
7.	प्राकृत भाषा के संरक्षण में संस्कृत साहित्य का योगदान -डॉ. सुदर्शन मिश्र	98
8.	पाली एवं प्राकृतों का परस्परिक संबंध - प्रो. धर्मचंद जैन	119
9.	प्राकृत का हिंदी को योगदान - डॉ दिलीप धींग	128
10.	बिहार की भाषाओं के विकास में प्राकृतों का योगदान -प्रो. ऋषभचंद जैन	133
11.	प्राकृत और पंजाबी भाषा सम्बन्ध - प्रो. प्रद्युम्नशाह सिंह	157

12. मागधी प्राकृत की उत्पत्ति और विकास
- डॉ. सुदर्शन मिश्र 165
13. प्राकृत संस्कृत मैत्री
- प्रो. वीरसागर जैन 180
14. प्राकृत और सिंधी भाषा संबंध
- डॉ. यशोधरा वाधवाणी 183
15. संस्कृत साहित्य में प्राकृत की उपादेयता
- डॉ. गिरीश कुमार शर्मा 197
16. प्राकृत एवं गुजराती भाषा संबंध
- डॉ. कुणाल एम कपासी 206
17. प्राकृत तमिल संबंध और प्रभाव
- डॉ. दिलीप धींग 218
18. कन्नड़ भाषा में प्राकृत व्याकरण
-डॉ. शांतिसागर शिरहट्टि 224
19. महाराष्ट्री प्राकृत एवं मराठी भाषा का अंत:संबंध -
प्रो. महावीर शास्त्री 241
20. प्राकृत का राजस्थानी पर प्रभाव
- डॉ. देव कोठारी 256
21. प्राकृत और बुंदेली भाषा का संबंध -
प्रो. कल्पना जैन 276
22. प्राकृत भाषा विकास और संरक्षण के उपाय
-डॉ. धर्मेन्द्र कुमार जैन 284
23. प्राकृत संस्कृत विभक्तियों की तुलना
-डॉ. ज्योति बाबू जैन 289
24. प्राकृत भाषा और ब्राह्मी लिपि
- डॉ. शुद्धात्मप्रकाश जैन 295
25. Influence of prakrit on Bengali phonology -
Pro. Jagat Ram Bhattacharya, Santiniketan 300

सम्पादकीय

विद्वद्वरेण्य पाइयविण्णो प्रो. जिनेन्द्र कुमार जैन, उदयपुर के सम्मानार्थ ग्रन्थ "णव-सिजणं" का प्रकाशन किया जा रहा है। यह हमारा परम सौभाग्य है कि हमें इस ग्रन्थ के सम्पादन का उत्तरदायित्व प्राप्त हुआ है। सभी सनेही मित्रों एवं गुरुओं की सतत प्रेरणा से ही इस ग्रन्थ का प्रकाशन सम्भव हो पा रहा है। ग्रन्थ के निर्माण हेतु पावन आशीर्वाद परमपूज्य प्राकृतशिरोमणी आचार्यश्री सुनीलसागरजी महाराज, परमपूज्य प्रज्ञाश्रमण अमितसागरजी महाराज एवं परमपूज्य मुनिश्री प्रणम्यसागरजी महाराज और परम-संरक्षक के रूप में परमपूज्य जगद्गुरु कर्मयोगी स्वस्तिश्री चारुकीर्ति भट्टारक महास्वामीजी, श्रवणबेलगोला का आशीर्वाद प्राप्त हुआ है, साथ ही संरक्षक एवं परामर्श प्रदानकर्त्ता के रूप में प्रो. प्रेम सुमन जैन, उदयपुर, प्रो. ऋषभचंद जैन, वैशाली एवं प्रो. जय कुमार जैन, मुजफ्फनगर तथा देश के ख्यातिलब्ध वरिष्ठ विद्वानों से निरन्तर मार्गदर्शन प्राप्त हुआ है।

प्रस्तुत कृति 'णव-सिजणं' का नामकरण सार्थक और उद्देश्यपूर्ण है। जहाँ एक ओर इस नामकरण में नूतनता का संचार है वहीं दूसरी ओर प्राच्यविद्यानुरागी हमारे गुरुवर का सम्मान है।

इस ग्रन्थ के सम्पादन में उत्तरदायित्व का निर्वहन गुरुवर्य प्रो. जिनेन्द्र कुमार जी के आशीर्वाद से ही सम्भव हुआ है। अभिनन्दनीय गुरुजी के विराट् व्यक्तित्व और कृतित्व को 'णव-सिजणं" ग्रन्थ की सीमित परिधि में निबद्ध करना असंभव था। गुरुजी ने महती कृपा करके अपने शोधलेखों में से कुछ विशिष्ट आलेखों को 'णव-सिजणं' ग्रन्थ में प्रकाशित करने की अनुमति प्रदान की है। हमारा निवेदन स्वीकार करके गुरुजी ने अपना जीवन-वृत्त तथा साहित्यिक अवदान प्रदान कर भी हमें उपकृत किया है। यह कार्य उनके द्वारा ही संभव था। उन्होंने अपने इस कार्य को पूरा करने में बड़ा श्रम किया है। ग्रन्थ की प्रूफ रीडिंग का कार्य भी अत्यन्त कठिन था। यह कार्य भी गुरुजी के सहयोग से ही पूर्ण कर पाए हैं। गुरूजी के घर पर मुझे गुरुजी और गुरुमाता श्रीमती मीना जी का असीम वात्सल्य प्राप्त हुआ है।

गुरुजी प्राकृत भाषा, साहित्य एवं जैनविद्या के अनुरागी एवं विश्रुत मनीषी है। आपकी जैन विद्वानों के साथ-साथ जैनेतर विद्वानों में आपके कार्यशैली की बड़ी प्रतिष्ठा है। यही कारण है कि इस ग्रन्थ हेतु जैन विद्वानों के साथ-साथ अनेक जैनेतर विद्वानों ने भी शुभकामनाएँ प्रेषित की हैं। सम्माननीय गुरुजी की निःस्वार्थ श्रुतसेवा और सारस्वत साधना का ही फल है कि उन्हें आचार्य, मुनि एवं भट्टारकजी ने आशीर्वाद प्रदान किया है। इसमें वरिष्ठ मनीषियों ने अपनी शुभकामनाएँ प्रदान की हैं। हम परमपूज्य आचार्य, मुनिश्री, भट्टारकजी एवं वरिष्ठ मनीषियों को सादर नमन करते हुए कृतज्ञता ज्ञापित करते हैं। जिन विद्वानों, साधर्मियों एवं स्नेही साथियों ने अपनी शुभाशंसाएँ प्रेषित की हैं, उनका भी हृदय से आभार व्यक्त करते हैं। विशेषरूपेण हम हमारे कनिष्ठ एवं वरिष्ठ शोधार्थी साथियों का हृदय से आभार व्यक्त करते हैं, जिनके सहयोग एवं प्रेरणा से यह दुरूहकार्य परिपूर्ण हो सका है। हमने णव-सिजणं ग्रन्थ का सम्पादन यथासंभव मनोयोग से पूर्ण किया है, फिर भी इसमें यदि कुछ त्रुटियाँ शेष रह जाना स्वाभाविक है, तो उनके लिए हम क्षमाप्रार्थी हैं।

About the Editors

Prof. Shurveer S. Bhanawat has been working as a Professor and Head, Department of Accountancy and Business Statistics, at Mohanlal Sukhadia University, Udaipur. He is director of MFC and M.Voc (ATA). Having twenty-six years of teaching experience. He possesses degrees of M.Com (gold Medal), M. Phil, Ph.D. and C.S. (1) with all through first-class academic records. Sixty-eight research articles have been published so far in international and national journals. Out of these ten research papers had been awarded 'Best research paper" and two "Quality Papers" in Indian Accounting Conferences and International seminars. He has been awarded Silver Shield for Second Best Research Paper in 2021 and Certificate of appreciation in 2022 under ICAI International Research Award in taxation category by the ICAI, New Delhi. He is also author of textbooks entitled 'Business Statistics and Cost Accounting published in Hindi and English versions. Three edited books are on his credit. He has completed two research projects on 'Socio-Economic Implication of Carbon Taxation: An Exploratory Research and "Determination of Shareholders wealth: A quantitative Analysis". He got president scout's award (1985) from President of India.

Dr. Shilpa Vardia has been working as an Assistant Professor in the Department of Accountancy and Business Statistics, Mohanlal Sukhadia University, Udaipur. She is having eighteen years of teaching experience at the graduate and postgraduate levels. She is the convener of the MFC and PGDIT Programme. She is an executive member of the Indian Accounting Association. She possesses degrees of M.Com and Ph.D. with a thorough meritorious academic record. Twenty-five research articles have been published so far in the journal of international and national repute. Six research papers have been awarded as Best Research Paper at Indian Accounting Conferences and other conferences. She also got the Certificate of appreciation under ICAI International Research award, 2020 from the ICAI, New Delhi. She is also the co-author of a textbook entitled "Business Statistics" published in Hindi version.

Dr. Shilpa Lodha is Assistant Professor at Department of Accountancy and Statistics, Mohanlal Sukhadia University, Udaipur. Having more than twelve years of teaching experience at graduate and post graduate levels, she is a UGC NET (2010) & UGC NET-JRF (2012) qualified faculty actively involved in teaching, research and consultancy. She has also been UCC-PDF. She possesses degrees of M.Com. (Gold Medal), M.Phil. (Gold Medal), and Ph.D., with all through meritorious academic record. She has got the Best Research Paper award three times in International Conferences. Her 20 research papers have been published in journals of national and international repute. She is also a co-author of books entitled "Cost Accounting" published in Hindi version and "Corporate Accounting" published in Hindi and English.

Presently three authors have been working as PI and Co-PIs under RUSA- sponsored departmental project entitled "Block Chain Accounting: An Exploratory Research.

प्राकृत भाषा जनकल्याणी

डॉ. सुमत कुमार जैन

भारतीय भाषा परम्परा में 'प्राकृत' एक प्राचीन भाषा मानी जाती है। प्राकृत भाषा जनसामान्य की भाषा रही है। जनमानस या लोक का शिष्ट या नागरिक समाज से अपना एक विशिष्ट सम्बन्ध एवं महत्त्व रहा है। बिना शास्त्रीय चर्चा, अनुशीलन और मनन के लोकजीवन से उद्भूत अनुभव की बातें अपनी अद्भुत सटीकता रखती हैं। उनके देश की सीमा तो की जा सकती है, पर वे काल की सीमा से मुक्त सदाबहार होती हैं।

जैनधर्म के अन्तिम तीर्थंकर महावीर और महात्मा बुद्ध ने अपने धर्म के उपदेश जनमानस के लिए जनसामान्य की प्राकृत भाषा में दिया था, क्योंकि उस समय जन-जन के मानस-पटल पर कथ्य-भाषा के रूप में प्राकृत विद्यमान थी। श्रमण परम्परा के इन महापुरुषों के ज्ञान का संदेश सहजता, सरलता और सुबोधता से जनसामान्य तक पहुँच सके और वे अपना हित सम्पादन कर सकें, इस मुख्य प्रयोजन की सिद्धि हेतु प्राकृत भाषा में उपदेश दिया गया। इसीलिए जैनधर्म के आगम-ग्रन्थ और बौद्धों के त्रिपिटक प्राकृत भाषा में लिपिबद्ध किये गये। यह जनसाधारण के लिए उदारवृत्ति से सृजित कल्याणकारी साहित्य था, किसी वर्ग या जातिविशेष के लिए निर्धारित नहीं था। साहित्य सृजन का प्रधान उद्देश्य लोक-मंगल है। लोकमंगल लोकभाषा में अपेक्षाकृत अधिक लोकोपयोगी होता है।

भगवान् महावीर के द्वारा उपदेशित जनकल्याणी कार्य कौन से हैं? जो जीव मात्र के कल्याणार्थ प्राकृत भाषा में निहित हैं, मेरा प्रतिपाद्य विषय है। प्राकृत भाषा का माहात्म्य निम्न प्रकार से द्रष्टव्य है-

सव्वजीव-हिदकरा कहदु हो! का वट्टदि जणभासा।
तित्थयरा वि जं आसेज्ज, सा का अत्थि सुभासा।।
अणादिकालदो णारीणं वि, का हिदयमणुहरेदि।
का सा भासा, जा इह भरहे, मादुभासा वि वट्टदि।।

Scanned with OKEN Scanner

सव्वजीव-हिदकरा सुणदु हो! पाइअभासा लोए।
तित्थयराणं दिव्वझुणीए, भासेसा हि सोहदि।।
णिय-सुहदोच्चारणदो एसा, णारीण मणाणं हरदि।
सव्वा मादुसत्तिओ वयणे, पाइयभासा धरदि।।[1]

डॉ. देवेन्द्र कुमार शास्त्री के अनुसार "प्रत्येक देश और जाति के मूल संस्कार, उसकी अपनी भाषा, साहित्य तथा संस्कृति में निहित रहते हैं। जातीय-जीवन, लोक-परम्परा एवं सामाजिक नीति-रीतियों के अध्ययन से हमें उनकी पूरी जानकारी मिलती है, अतएव भाषा और साहित्य का प्रत्येक अंग लोक-मानस की अभिव्यक्ति का ही लिपिबद्ध स्वर होता है। मौखिक रूप में आज भी हमें गुणाढ्य की ही बृहत्कथा तथा प्राकृत और अपभ्रंश में लिखित कथाएँ, सूक्तियाँ, सुभाषित एवं अन्य उक्तियाँ गांवों में प्रचलित सुनाई देती हैं। वस्तुतः युग-युगों से साहित्यिक तथा सामाजिक परम्परा परस्पर विचारों का विनिमय करती आयी है, इसीलिए परम्परा में केवल इतिहास तथा पौराणिकता का लेखा-जोखा न होकर लोकजीवन में परिव्याप्त यथार्थ और आदर्श रूप-कुरूप, नीति और उपदेश तथा वृत्ति एवं रीति का भी समाहार हो जाता है"।[2]

भारतीय भाषा का विकास वैदिक काल में ही प्रारम्भ हो गया था। ऋग्वेद के वाक्सूक्त तथा अथर्ववेद के पृथ्वीसूक्त में स्पष्ट कहा गया है कि लोग देश के नाना क्षेत्रों में भिन्न-भिन्न प्रकार की बोलियाँ बोलते हैं। अशोक के शिलालेखों से भी प्रमाणित होता है कि एक ही प्राकृत भाषा उत्तर-पश्चिम और पूर्व के प्रदेशों में भिन्न-भिन्न प्रकार से बोली समझी जाती थी।[3]

प्राकृत भाषा को विशेष प्रोत्साहन तब मिला जब ई. पू. छठी सदी में भगवान् महावीर और महात्मा बुद्ध जैसे महापुरुषों का अवतरण हुआ और उन्होंने अपने-अपने धर्म सम्बन्धी उपदेशों के लिए उस समय उनकी विहारभूमि में प्रचलित जनभाषा को अपनाया और उन्होंने अपने शिष्यों को भी आदेश दिया कि वे उसी भाषा में उनके उपदेशों की ग्रन्थ रचना करें। यह भाषा मगध देश की होने से 'मागधी' तथा उसके सीमा से लगे हुए शूरसेनादि प्रदेशों के सीमावर्ती क्षेत्रों में प्रचलित बोलियों से भी प्रभावित होने के कारण अर्द्धमागधी कहलायी। दुर्भाग्यतः जिस रूप में उक्त उपदेशों की प्रथम ग्रन्थ रचना हुई होगी, वह रूप हमें अब उपलब्ध नहीं है। बुद्ध के उपदेशों पर आधारित पालि-साहित्य का वर्तमान स्वरूप उसे बुद्ध से सदियों पश्चात् लंका में प्राप्त हुआ था। महावीर के उपदेशों पर आधारित 'द्वादशांग' आगम आज जिस रूप में उपलब्ध है, वह रूप ईसा की पाँचवीं सदी में हुई वल्लभीपुर वाचना का है।

Scanned with OKEN Scanner

प्राकृत भाषा का जो स्वरूप प्राप्त होता है वह प्राकृत का आदिकाल तथा भारतीय आर्यभाषा का द्वितीय या मध्यम स्तर माना जाता है। यह मध्यम स्तर अपने आदि रूप में यद्यपि व्याकरण की दृष्टि से संस्कृत भाषा की अपेक्षा बहुत भिन्न और सुगम है, तथापि उसमें संस्कृत की ध्वनियाँ बहुत कुछ समान पायी जाती हैं। यह स्तर हमें ई. की द्वितीय-तृतीय सदी तक रचे गये ग्रंथों, जैसे-पालित्रिपिटक, अश्वघोष के नाटक तथा राजा अशोक, खारवेल, आंध्रनरेशों के शिलालेखों में प्राप्त होता है।[4]

तत्पश्चात् मध्ययुगीन भाषा का द्वितीय स्तर प्रारम्भ हुआ। इसकी क्रान्तिकालीन परिस्थिति महाकवि भास के नाटकों में देखी जा सकती है। इसका विशेष लक्षण यह है कि शब्दों के क, ग, त, द आदि अल्पप्राण वर्णों का लोप होकर उनके स्थान में मात्र अ, इ आदि स्वर शुद्ध अथवा उच्चारण सौकर्य हेतु य से मिश्रित पाये जाते हैं तथा ख, घ, थ, ध आदि महाप्राणों के स्थान में 'ह' का आदेश कर दिया जाता है। इस प्रवृत्ति से प्रभावित वह समस्त प्राकृत साहित्य है जो विशेष रूप से तीसरी-चौथी सदी से लेकर छठी-सातवीं सदी तक रचा गया। यह मध्य व्यंजनों के लोप की प्रक्रिया महाराष्ट्री प्राकृत का विशेष लक्षण है और उसकी प्रतिनिधि रचनाएँ कालिदास कृत नाटकों के प्राकृत अंश, सेतुबंध, गाथासप्तशती, गउडवहो आदि हैं।[5]

हिन्दी आर्य भाषा के मध्यकाल का तृतीय स्तर का प्रतिनिधित्व करने वाली अपभ्रंश भाषा और उसका साहित्य है।

जनकल्याणी कार्य से तात्पर्य है, जिन कार्यों के निष्पादन से लोककल्याण सम्भव होता है। जो व्यक्ति के आत्मिक विकास में सहायक होते हैं तथा जिनसे समाज का नैतिक-आधार दृढ़ होता है। आगम-ग्रन्थों में प्रायः ऐसे कार्यों को अंकित करने का प्रयत्न किया गया है जो मानव मात्र को सद्भाव में प्रेरित करते हैं, मानव मात्र के लिए कल्याण का साधन बनकर पृथ्वीतल को सुखसम्पन्न एवं शान्ति-भूषित स्वर्ग के रूप में परिणत करने की क्षमता रखते हैं तथा जिनका अनुसरण लोकस्तर को ऊँचा उठाता है। इन्हीं उद्देश्यों के पूर्ति के लिए मुनि, आचार्य मनीषी लोक-वाणी प्राकृत में ग्रन्थों का प्रणयन करते हैं।

आगमों का प्रयोजन भी लोककल्याण से ओतप्रोत आदर्श तथ्यों की स्थापना करना ही रहा है। इसके अन्तर्गत अहिंसा की प्रतिष्ठा, आत्मशुद्धिपरक आध्यात्मिक-चिंतन, नैतिकजागरण, ग्राम्यजीवन की झांकी, आहारशुद्धि, सांस्कृतिक सौहार्द, सद्भाव एवं समन्वय, शिक्षा का महत्त्वपूर्ण घटक अनुशासन एवं विनय, सहनशीलता की मिशाल परिषहजय, मानवता, सद्धर्म श्रवण, जागरुकता का संदेश, परोपकारवृत्ति, संतोषवृत्ति- लोभ की अभिवृद्धि पर रोक, आहारशुद्धि, कर्म-प्रधान समाज, ब्रह्मचर्य व्रतों का राजा, अनुशासनहीनता का प्रतीक अविनय, उत्कृष्ट नारी-चरित्र, जातिवाद

व्यवसाय(पुरुषार्थ) में रहती है। यथा-

अप्पाणं अणुमन्ता जे आरंभन्ति दुग्गमं।
कज्जं परमुहपलोइयाणं, ताण कह होइ जयलच्छी।
न महुमहणस्स वच्छे मज्झे कमलाण नेय खीरहरे।
ववसायसायरे सुपुरिसाण लच्छी फुडं वसइ।।

परोपकारवृत्ति- परोपकार से अभिप्राय है- दूसरों का उपकार, दूसरे पर अनुग्रहबुद्धि, अन्य के प्रति भलाई का भाव।[9]

प्रो. सोगानी जी के अनुसार जनता में आस्था या विश्वास उत्पन्न होने से व्यक्ति में जो मूल्य-वृत्ति सबसे पहिले उत्पन्न होती है, वह है, पर उपकार वृत्ति।[10]

जनकल्याण के कार्यों का उल्लेख प्राकृत भाषा में सम्राट अशोक ने अपने शिलालेखों में किया है।[11] परोपकार के सम्बन्ध में मनुष्यों एवं पशुओं के बीच कोई भेद-भाव नहीं रखा गया है। कल्याण कार्यों में औषधियों और फल-वृक्ष के रोपे जाने, सड़कों पर मनुष्यों और पशुओं के लिए छायादार वृक्ष, आम्रवृक्षों की वाटिकाएँ, कुएँ, तालाब एवं जलासय का निर्माण, विश्रामगृह के निर्माण आदि के उल्लेख प्राप्त होते हैं।[12] उपकार वृत्ति के माहात्म्य बताते हुए कहा गया है कि दो प्रकार के पुरुषों ही पृथ्वी को धारण करते हैं, एक तो वह जिनकी बुद्धि उपकार में लगी रहती है तथा दूसरे वे जो किये गये उपकार को नहीं भूलते हैं। यथा-

वे पुरिसा धरइ धरा अहवा दोहि पि धारिया धरणी।
उवयारे जस्स मइ उवयरियं जो न पम्हुसई।।

समत्वदृष्टि- राग-द्वेष में समत्वदृष्टि। किसी को मत मारो, चोट मत पहुँचाओ, परिताप मत करो, क्लेश मत दो। आचारांग में कहा है-'हे मनीषियों! आपको दुःख प्रिय है या अप्रिय? यदि आप कहें कि दुःख प्रिय नहीं है, तब आपके इस सम्यक् उत्तर पर कहना चाहेंगे कि जैसे आपको दुःख प्रिय नहीं है, वैसे ही सब प्राणी, भूत, जीव और सत्त्वों के लिए दुःख अप्रिय, अशांतिजनक और महाभयंकर है।[13]

अन्यत्र यह भी कहा गया है कि व्यक्ति को विपत्ति और दुर्भाग्य के समय शान्ति और धैर्यपूर्वक जीवन-यापन करने का निर्देश दिया गया है, क्योंकि विपत्ति में ही सम्पत्ति और दुर्भाग्य में ही सौभाग्य का निवास रहता है। गाहासत्तसई में कहा गया है कि सज्जन पुरुष विपत्ति में उद्वेग रहित, सम्पत्ति में गर्व रहित, भय में धैर्य तथा समता-विषमता में अपरिवर्तित स्वभावी होते हैं। यथा-

वसणम्मि अणुव्विग्गा विहवम्मि अगव्विआ भए धीरा।
होन्ति अहिण्णसहावा समेसु विसमेसु सप्पुरिसा।।

Scanned with OKEN Scanner

विवेकसहित ज्ञान की जागृति- 'विवेक' व्यक्ति को हेय-उपादेय की पहचान कराने वाला चक्षु है। इस चक्षु के माध्यम से अच्छे और बुरे की पहचान की जा सकती है। विवेक ही मनुष्य को पशु से भिन्न करता है। विवेकमंजरी के मंगलाचरण में उन वीर प्रभु को नमस्कार किया है जो विवेकरूप दीपक से युक्त है और प्राणीमात्र को परमार्थ का ज्ञान कराते हैं-

सिद्धपुर सत्थवाहं वीरं णमिऊण वरं जिणनाहं।
सवण सुहारससरिअं वुच्चामि विवेकमंजरी अं।।1।।
दुट्ठकम्मवसगा भमंति भीम भवंमि निस्सीमं।
भद्द विवेकपईवो जीवाणं मुणंति परमत्थं।।2।।

विवेक की महिमा बताते हुए कहा है कि विवेकपूर्ण आचरण से मन की शुद्धि होती है।[14] इस शुद्धि के चार कारण निरूपित किये गये हैं - 1.चार शरणों (चत्तारिसरणं) की स्वीकृति 2.गुणों की सच्ची अनुमोदना 3.पापों की निन्दा और 4.बारह भावनाएँ। विवेक सहित ज्ञान शिक्षित करता है, ज्ञान गुणी बनाता है, ज्ञान पर को उपदेश देता है, ज्ञान से न्याय किया जाता है और ज्ञान से ही विनयी होता है। पद्मनंदि-पंचविंशति[15] ग्रन्थ में कहा है कि जो जन उत्तम गुरु के द्वारा प्ररूपित शास्त्र को नहीं पढ़ते हैं, उन्हें बुद्धिमान मनुष्य दोनों नेत्रों से युक्त होने पर भी अन्धा समझते हैं। जिनके अन्दर ज्ञान रूपी ज्योति जल जाती है, उनकी बुद्धि कभी मैली नहीं होती है।[16] यह भी कहा है कि ज्ञान के समान संसार में दूसरा कोई सुख का कारण नहीं है, क्योंकि यह ज्ञान ही जन्म, जरा और मृत्यु रूपी रोग दूर करने के लिए अमृत के समान है।[17] ज्ञान के बिना मोक्षमार्ग की प्राप्ति नहीं हो सकती है।[18] इस प्रकार ज्ञान की अद्वितीय महिमा बतायी गयी है।

शिक्षा का महत्त्वपूर्ण घटक अनुशासन एवं विनय-विनय का जीवन में अत्यन्त महत्त्व है। विद्या से विनय आती है। विनशीलता व्यक्तित्व की पहचान है। उत्तराध्ययनसूत्र के विनय नामक अध्ययन में विनय और अविनय के स्वरूप का विवेचन करते हुए कहा है कि अविनीत शिष्य सूकर और कुतिया की तरह होता है, वह सभी के लिए हेय होता है, जबकि विनीत शिष्य मेधावी होता है और वह गुरु एवं सभी के लिए उपादेय होता है।[19] विनीत का कथन करते हुए कहा गया है कि वह गुरु की आज्ञा और निर्देश का पालन करता, गुरु की शुश्रुषा करता है, गुरु के इंगित और आकार को जानता है। बिना पूछे कुछ नहीं बोलता, पूछने पर असत्य नहीं बोलता, क्रोध आ जाए तो उसे जीत लेता है, प्रिय और अप्रिय को अंगीकार करता है अर्थात् गुरु जैसा कहे उसे शिरोधार्य करता है।[20]

वर्तमान में विपरीत मार्ग पर चल रहे शिक्षार्थियों के सम्यक् बोध हेतु उत्तराध्ययन में वर्णित है कि विद्यार्थी की योग्यता एवं अयोग्यता क्या हो? इस हेतु बहुत ही मर्मस्पर्शी वर्णन किया गया है। यहाँ विद्यार्थी की योग्यता के लिए कहा है कि उसका आचार्यकुल में रहना, उत्साही, विद्या-प्रेमी, मधुरभाषी तथा शुभकर्मा होना आवश्यक माना गया है।[21] विद्यार्थी की योग्यताओं का विवेचन करते हुए उसमें इन आठ[22] गुणों का रहना आवश्यक बताया गया है- सहनशीलता, इन्द्रियनिग्रही, मधुर भाषी, शीलवान, रसों में अलोलुपता, अक्रोधी, शीलवृत्ति की दृढ़ता और सत्यभाषी। आदिपुराण के अनुसार विद्यार्थी में जिन मौलिक गुणों का होना अनिवार्य है, वे ये हैं[23] - जिज्ञासावृत्ति, श्रद्धा (अध्ययन और अध्यापक दोनों के प्रति आस्था), विनयशीलता, शुश्रूषा, श्रवण (पाठ-श्रवण के प्रति सतर्कता एवं जागरूकता), ग्रहण (गुरु द्वारा अध्यापन किए गए विषय को ग्रहण करने की अर्हता), धारणा (पठित विषय को सदैव स्मरण रक्षने की क्षमता), स्मृति (कालान्तर में नहीं भूलना), ऊह (तर्कणा-शक्ति), अपोह (पठित ज्ञान के आधार पर विचार-शक्ति का प्राबल्य एवं अकरणीय त्याग), निर्णीति (विचार करने की क्षमता), संयम, प्रमाद का अभाव, सहज प्रतिभा (विशेष क्षयोपशम शक्ति) और अध्यवसाय।

उक्त तथ्यों के आलोक में यह कहा जा सकता है कि आज जनजीवन में अशान्ति और अनुशासनहीनता के काले बादल मँडरा रहे हैं। उसका मूल कारण जीवन में विनय का अभाव है और अहंकार की वृद्धि है तथा विनय का अभाव परिवारिक, सामाजिक, राष्ट्रिय जीवनशैतान की आँत की तरह बढ़ रहा है, जिससे न परिवार सुखी है, न समाज सुखी है और न राष्ट्र के अधिनायक ही शान्ति में है।

आत्मतुला-प्राकृतिक पदार्थों तथा जिनमें जीवन का अस्तित्व है, चेतना है, ऐसे सजीव पदार्थों का मानव-जीवन के साथ गहरा सम्बन्ध है। तत्त्वार्थसूत्र में कहा गया- 'परस्परोपग्रहो जीवानाम्'[24] अर्थात् जीवों का स्वभाव परस्पर उपकार करना होना चाहिए। यही कारण है कि जैनधर्म के अन्तिम तीर्थंकर भगवान् महावीर ने कहा- धम्मं चरणस्स पंच निस्सा ठाणा तं जहा- छक्काए गणे राया सरीर अर्थात् जो व्यक्ति आध्यात्मिक धर्म का आचरण(साधना) करना चाहता है, उसके लिए निम्न पाँच स्थानों पर आलम्बन लेना बताया है। जैसे कि षट्कायिक जीव, गण, शासक, गृहपति और शरीर। इस सूत्र में छह काय (एकेन्द्रिय से लेकर पंचेन्द्रिय तक) के जीवों के आश्रय को प्राथमिकता दी गई है। अतएव जैनागमों में पृथ्वी, जल, अग्नि, वायु और वनस्पति में जीवन का अस्तित्व स्वीकार किया है एवं इन सभी का विस्तार से निरूपण प्राप्त होता है। ये जीव कहाँ-कहाँ रहते हैं? उनका शरीर किस-किस प्रकार का है, वे कैसे-कैसे श्वासोच्छवास, आहार आदि ग्रहण करते हैं? उनका विकास-

ह्रास कैसे-कैसे होता है? उनकी उत्कृष्ट आयु कितनी है? उनमें कितनी इन्द्रियाँ हैं, कितने प्राण है?- इन सभी प्रश्नों पर बहुत गहराई से विचार प्रस्तुत किया गया है।

क्षमा- क्षमा का अर्थ सहनशीलता है। बारस अणुवेक्खा के अनुसार क्रोध के उत्पन्न होने के साक्षात् बाहरी कारण मिलने पर भी जो थोड़ा भी क्रोध नहीं करता है, उसे उत्तम क्षमा धर्म होता है।[25] कार्तिकेयानुप्रेक्षा में कथन है कि देव, मनुष्य और तिर्यंचों द्वारा घोर व भयानक उपसर्ग पहुँचाने पर भी जो क्रोध से तप्त नहीं होता, उसे निर्मल क्षमाधर्म साधित होता है-

कोहेण जो ण तप्पदि, सुर-णर-तिरिएहि कीरमाणे वि।
उवसग्गे वि रउद्दे, तस्स खमा णिम्मला होदि।।

व्यक्ति को जहाँ तक सम्भव हो, वहाँ तक क्षमा धारण करना चाहिए। सभी प्राणियों के प्रति सुरक्षा, संयम, समुचित व्यवहार और मृदुता की भावना होनी चाहिए। यहाँ तक कहा गया है कि जो क्षमा करने में समर्थ हैं जो धनवान गर्व नहीं करते और विद्वान् विनम्र होते हैं- इन्हीं तीनों से पृथ्वी अलंकृत है। यथा-

जे जि खमेइ समत्थो, धणवन्तो जं न गव्वं उव्वहइ।
जं च सविज्जो नमिओ, तिसु तेसु अलंकिया पुहवी।।-

कार्तिकेयानुप्रेक्षा, गाथा-150

संयम-सम्यक् रूप से यम अर्थात् नियंत्रण संयम है[26] और आत्मा की रुचि का नाम भाव है जो सम्यक्त्व का कारण होता है।[27] शुद्ध चैतन्य शुद्धभाव है।[28] राजवार्तिक (9.6.16.596.1) के अनुसार भावशुद्धि संयम की आठ शुद्धियों में से एक है।

प्राकृत-मनीषियों ने जीवकायसंजमे अजीवकायसंजमे य अर्थात् जैसे जीवकाय के प्रति संयम रखने की प्रेरणा दी है, वैसे ही अजीवकाय (जड़, प्रकृतिजन्य वस्तुएँ या पुद्गलों) के प्रति भी संयम रखने की प्रेरणा दी है, किन्तु, आधुनिक समय में मानव इस तथ्य का नजरअंदाज करके जीवकाय और अजीव-काय दोनों प्रकार के पर्यावरण-संतुलन के लिए उपयोगी सजीव-निर्जीव पदार्थों के प्रति अधिकाधिक असंयम करके अंधाधुंध रूप से संतुलन बिगाड़ने का पराक्रम करके प्रदूषण फैला रहा है। षट्खण्डागम एवं समवायांगसूत्र के सत्रहवें समवाय में संयम का विस्तार से वर्णन उपलब्ध होता है- पृथ्वीकायिक-संयम, अप्कायिक-संयम, तेजस्काय-संयम, वायुकाय-संयम, वनस्पतिकाय-संयम, द्वीन्द्रिय-संयम, त्रीन्द्रिय-संयम, चतुरिन्द्रिय-संयम, पंचेन्द्रिय-संयम, अजीवकाय-संयम, प्रेक्षा-संयम, उपेक्षा-संयम, अपहृत्य-संयम, प्रमार्जना-संयम, मन:संयम, वचन-संयम, और काय-संयम। इन संयम के प्रकारों में पृथ्वीकायिक आदि नौ प्रकारों के जीवों के प्रति संयम रखना, उन जीवों

को कष्ट हो, त्रास हो, ऐसी प्रवृत्ति नहीं करना है। अजीवकाय संयम में प्रकृतिजन्य सभी निर्जीव पदार्थों के प्रति संयम की प्रेरणा है। प्रेक्षा, उपेक्षा, अपहृत्य एवं प्रमार्जना रूप संयम में प्रत्येक प्रवृत्ति करते समय देखें, पूर्वापर का, परिणाम का विचार करें, जिस स्थान पर या प्रवृत्ति में जीवहिंसा अधिक हो, जिससे अपने स्वास्थ्य परिवार एवं समाज की हानि हो, उस प्रवृत्ति के प्रति उपेक्षा करें। जहाँ सींचना, खोदना आदि हो वहाँ भी संयम रखें, ताकि किसी जीव को पीड़ा न हो, क्रोधादि में संयम रखें।

जीवन का सर्वांगीण विकास करना संयम का परम उद्देश्य है। समस्त प्राणियों में संयमभाव ही अहिंसा है- "अहिंसा निउणं दिट्ठा सव्वभूयेसु संजमा"[29] उसके सुख संयम में प्रतिष्ठित है। मन, वचन, काय से संयमी व्यक्ति स्व-पर का रक्षक तथा मानवीय गुणों का आगार होता है। शील संयमादि गुणों से भरपूर व्यक्ति ही सत्पुरुष है और ऐसे सत्पुरुष ही पर्यावरण का रक्षक होते हैं।

सदाचार- सामान्य सदाचार को धर्म का आधार बताते हुए वर्णित है कि "माता-पिता की शुश्रुषा, वृद्धों की शुश्रुषा, गुरुओं की शुश्रुषा, जीवों के प्रति दया, सत्यभाषण, शिष्यों द्वारा आचार्य का आदर और सम्बन्धियों के प्रति समुचित बर्ताव- ये सभी धर्म के तत्त्व हैं।[30] ये सभी आधार धर्म को पूर्णतया व्यवहारिक रूप में प्रस्तुत करते हैं। अशोक के अभिलेखों में धर्म के निम्नलिखित लक्षण उल्लिखित हैं।[31] -

अपासिनवे (पापों से दूर रहना), बहुकयाने (अनेक कल्याणकारी कार्य करना), दया (दीन-दु:खी प्राणियों पर दया करना), दान (आवश्यकतानुसार यथाशक्ति सभी को दान देना), सचे (सत्य बोलना) और सोचये (शरीर, वचन और विचार की शुद्धता)।

उत्कृष्ट नारी-चरित्र- भारतीय संस्कृति में नर की अपेक्षा नारी की विशेषता सिद्ध करने का प्रयास किया है। नारियों की प्रशंसा में कहा गया है कि "नार्यस्तु यत्र पूज्यन्ते रमन्ते तत्र देवता" जिस घर में स्त्रियों का सम्मान होता है, वहाँ देवता भी आनन्दपूर्वक निवास करते हैं। वस्तुत: घर को सुख-समृद्धि से परिपूर्ण बनाने में नारियों का ही प्रथम हाथ होता है। पुरुष तो हमेशा एक रूप में ही दिखाई पड़ता है, जबकि स्त्रियाँ अपने विविध रूप में होकर अपने उत्तरदायित्व को पूर्ण करती हैं। मुख्यत: नारियों के कन्या, पत्नी और माता रूप होते हैं। इन सभी रूपों की अभिव्यक्ति कण्हचरियं में उपलब्ध होती है। कण्हचरियं में राजीमती का कन्या के रूप में उत्कृष्ट आदर्श वर्णित है, जो अनुकरणीय की श्रेणी में रखे जाने योग्य है।

शीलवती स्त्री के रूप में राजीमती का जैसा वर्णन उत्तराध्ययन में वर्णित है, वह अन्यत्र दुर्लभ है। नेमिनाथ के लघुभ्राता रथनेमि राजीमती से विवाह का प्रस्ताव रखता है, तो वह स्पष्ट ही मना कर देती है, क्योंकि उसने मन से नेमिकुमार को अपना

Scanned with OKEN Scanner

जीवन-साथी स्वीकार कर लिया था। पुनः जब साध्वी के रूप में पवित्र राजीमती को रथनेमि विषयभोग के लिए प्रेरित करता है, तब वह उन्हें फटकारती है और प्रतिबोधित करती है। जैसे कहा है-

धिरत्थु ते जसोकामी! जो तं जीवियकारणा।
वंतं इच्छसि आवेउं सेयं ते मरणं भवे।।[22]

अर्थात् हे यशःकामिन! धिक्कार है तुझे जो तू भोगी जीवन के लिए वमी हुई वस्तु को पीने की इच्छा करता है। इससे तो तेरा मरण श्रेष्ठ है। इन बोधवचनों से राजीमती संयम से भटके रथनेमि को प्रतिबोधित कर सन्मार्ग पर लाती है। यहाँ राजीमती के रूप में नारी के उदात्तता का चित्रण किया गया है।

महाकवि हाल ने गाहासत्तसई में नारी के उत्कृष्ट-नारी चरित्र को उद्घाटित कर लोकजीवन के मूल्यों की स्थापना की है। कुछ उदाहरण इस प्रकार हैं:-

साहीणे विपिअअमे पत्ते वि खणे ण मंडिओ अप्पा।
दुग्गअ-पउत्थ-वइअं सअज्जिअं संठवंती ए।।- 1/39

अर्थात् अपने पति के प्रवास से वापस आ जाने पर भी नायिका कुसुंबी चीर इसलिए धारण नहीं करती है कि पड़ोसन एक तो गरीब है और दूसरे प्रोषितपतिका भी, अतः उसके मन को दुःख न पहुँचे। ऐसी परदुःखकातरता यदि आज नायिकाओं में आ जाए तो क्या बात है?

दिअरस्स असुद्धमणस्स कुलवहू णिअअ कुड्डु लिहिआइं।
दिअहं कहेइ रामाणु लग्गा सोमित्त-चरिआइं।।-1/35

अर्थात् अपनी भाभी पर बुरी नजर रखने वाले बिगडैल देवर को नायिका दिन-रात लक्ष्मण का चरित्र सुनाती है। ताकि वह देवर-भाभी के संबंधों की मर्यादा व पवित्रता को पहिचाने। वह सीधे डॉट सकती थी या पति से देवर की शिकायत कर सकती थी, परन्तु इससे संयुक्त परिवार की निश्चित ही हानि होती। इसलिए स्वयं व्यथा सही, परन्तु देवर को लक्ष्मण कथा कही।

अइकोवणा वि सासू रुआविआ गअवईअ सोण्हाए।
पाअपडणोण्ण आए दोसु वि गलिएसु वलएसु।।-5/93

अर्थात् सास के पैर छूने के लिए झुकने पर बहु के दोनों वलय(कंगन) गिर पड़े- बहु की ऐसी कृश-दशा देखकर गुस्सैल सास भी करुणा से रो पड़ी। यह आदर्श हाल के अतिरिक्त कौन प्रस्तुत कर सकता है?

सदगृहस्थ नारी के लक्षण वज्जालग्गं में वर्णित है कि जो नारी परिवार के समस्त सदस्यों के भोजन कर लेने के उपरान्त भोजन करती है, सभी परिजनों के सोने

Scanned with OKEN Scanner

के पश्चात् सोती है और प्रातःकाल सर्वप्रथम जाग उठती है, वह सामान्य गृहिणी नहीं, घर की लक्ष्मी है-

भुंजइ भुंजियसेसं, सुप्पइ सुत्तम्मि परियण सयले।
पढमं चेय विबुज्झइ, घरस्स लच्छी न सा घरिणी।।

-वज्जालग्गं, गाथा

इस प्रकार नारियाँ जहाँ भोग्योपभोग, ऐहिकसुख एवं सन्तानोत्पत्ति की साधन मानी जाती हैं, वहाँ अपने शील और संस्कृति की रक्षा करना अत्यन्त अनुकरणीय है।

आहारशुद्धि

प्राकृत साहित्य में स्वस्थ जीवन के लिए आहार-विज्ञान की उपयोगिता दृष्टिगत होती है। हमारा आहार कैसा हो? इस प्रश्न पर प्राचीन समय से ही निरन्तर चिंतन-मनन किया जाता रहा है। साधना और स्वास्थ्य, आहार-विज्ञान के मुख्य केन्द्र बिन्दु हैं।

स्वास्थ्य की दृष्टि से आहार का बहुत बड़ा महत्त्व है। आहार का सामान्य अर्थ है कि भोजन व पेय। आहार-विज्ञान का अर्थ है- वह विज्ञान जिसमें खाद्य पदार्थों के गुण-दोषों, पोषक तत्त्वों आदि का वर्गीकरण किया जाता है। प्राकृत साहित्य में आहार के चार प्रकार बतलाये हैं- अशन, पान, खाद्य और स्वाद्य। आवश्यक निर्युक्ति में विवेचित है-

असणं पाणगं चेव, खाइमं साइमं तहा।
एसो आहारविही, चउव्विहो होइ नायव्वो।।
आसुं खुहं समेई, असणं पाणाणुवग्गहे पाणं।
खे माइ खाइमं ति य, सएइ गुणे तओ साई।।-गाथा,1587-1588

अर्थात् अशन-जो क्षुधा का शीघ्र शमन करता है, भूखे व्यक्ति द्वारा जिसे खाया जाता है, उसे अशन कहते हैं। जैसे चावल आदि। पान- जो प्राणों का उपग्रह करता है, जिसे पीया जाता है, उसे पान कहते हैं। जैसे द्राक्षा का पानक आदि। खाद्य-जो मुखविवर में समा जाता है, जिसे खाया जाता है, उसे खादिम या खाद्य कहते हैं। जैसे मोदक, खजूर आदि। स्वाद्य- जिसका स्वाद लिया जाये जो मुखवास के रूप में काम आए, उसे स्वादिम अथवा स्वाद्य कहते हैं। जैसे ताम्बूल, सोंठ आदि।

प्राकृत साहित्य में आहार-विज्ञान से सम्बन्धित चर्चा माँस, मधु और पंच उदुम्बरफल का त्याग, रात्रिभोजनत्याग, जलगालन आदि के माध्यम से की गई है और अनशन, अवमौदर्य, वृत्तिपरिसंख्यान, रसपरित्याग आदि के माध्यम से आहार-शुद्धि को बताया गया है।

बहुत से लोग सही और गलत आहार से अनभिज्ञ हैं, वे इन दोनों के अन्तर को समझने में असमर्थ हैं। प्राकृत साहित्य में आहार-शुद्धि पर गहराई से चिन्तन-मनन किया गया है। इस साहित्य में वर्णित है कि अनशन, अवमौदर्य, रसपरित्याग आदि आहार शुद्धि के कारण हैं। इन तथ्यों को आज का विज्ञान भी स्वीकार करता है। यहाँ गाथा में द्रष्टव्य है-

अप्पाहारस्स न इंदियाई विसएसु संपत्तंति।
नेव किलम्मइ तवसा रसेसु न सज्जए यावि।।
थोवाहारी थोवभणियो य, जो होइ थोवनिद्दो य।

अर्थात् अल्पाहारी की इन्द्रियाँ विषयभोगों की ओर नहीं दौड़ती, तप करने पर भी क्लांत नहीं होती और न स्वादिष्ट भोजन में आसक्त होती हैं। जो साधक कम खाता है, कम बोलता है, कम नींद लेता है और धर्मोपकरण की सामग्री कम रखता है, उसे देवता भी नमन करते हैं।

वर्तमान में पाश्चात्य संस्कृति ने हमारी प्राचीन संस्कृति पर चारों ओर से आक्रमण किया है। परिस्थितियों ने भी करवट ली है। जंकफूड, फास्टफूड, पिज्जा आदि जैसे आधुनिक आहार प्रकारों ने एक ओर हमारे स्वास्थ्य पर आघात किया है, मधुमेह, ब्लड प्रेशर, हृदय रोग जैसी अनेक बीमारियों को आमन्त्रित किया है तो दूसरी ओर होटल संस्कृति ने हमारे आहार को अशुद्ध बना दिया है। जिसका असर हमारी मन-वचन-काय की क्रियाओं पर पड़ा है। निश्चित ही हमारे आहार से हमारे भाव प्रभावित होते हैं। भावों की शुद्धता के लिए आहार-शुद्धि एक आवश्यक और अपरिहार्य तत्त्व है, इसलिए कहा गया है-जैसा खाओ अन्न, वैसा होवे मन, जैसा पियो पानी, वैसी होवे वाणी।

संतोषवृत्ति

संतोष शब्द की व्युत्पत्ति है-समतुघज। संतोषवृत्ति का अर्थ है कि जो मिले उसी में प्रसन्न रहने की वृत्ति, संतोषवृत्ति है। संतोष के अन्य अर्थ है- तृप्ति, प्रसन्नता और धैर्य। जीवन में जिस मानव में संतोषवृत्ति होती है, उसका जीवन संयमित एवं सुखद होता है। स्वयं के प्रति उनकी श्रद्धा-आस्था होती है, वे जीवन में दुःखों के क्षणों का धैर्य और साहसपूर्वक मुकाबला करते हैं। संतोष के विपरीत तृष्णा को वर्णित करते हुए कहा है कि जिस प्रकार पाताल की गहराई और सागर की लहरों से उस वडवानल की तृष्णा बुझती नहीं है ,[33] उसी प्रकार मानव का तृष्णा रूपी गड्ढा भी कभी भरता नहीं है। अतः इच्छाओं को सीमित कर संतोषवृत्ति को अपनाना चाहिए। संतोष वृत्ति को धारण करने से ही मानव सुखी होती है।

Scanned with OKEN Scanner

द्वादशानुप्रेक्षा में सहिष्णुता के सम्बन्ध में कहा गया है कि व्रती पुरुष उपसर्ग तथा तीव्र परिषह को ऋणमोचन-कर्ज चुकाने की तरह मानता है। वह जानता है कि ये तो मेरे द्वारा पूर्वजन्म में संचित किये गये कर्मों का ही फल है।[64] दशवैकालिक सूत्र में सहिष्णुता के सम्बन्ध में कहा है कि क्षुधा, प्यास व दुःशैय्या, विषमभूमि-युत वासस्थान, सर्दी, गर्मी, अरति, भय- इन कष्टों को मुमुक्षु अव्यथित चित्त से सहन करे। समभाव से सहन किये गये, दैहिक कष्ट महाफल के हेतु होते हैं।[65]

निष्कर्षतः संक्षेप में कहा जा सकता है कि उपरोक्त अहिंसा, अनुशासन, विनय, सहनशीलता परोपकारवृत्ति, संतोषवृत्ति, आहारशुद्धि, उत्कृष्ट नारी-चरित्र, सम्यक्-आजीविका आदि विषयक जनकल्याणी तथ्यों को सम्यक् विधि से अपनाता है तो अपना जीवन सुखी, समृद्ध और आनंदमय बना सकता है। अपने परिवार में माता-पिता तथा वृद्धों की सेवा एवं आदर भाव, गुरुजनों के प्रति सेवा एवं आदर भाव, सम्बन्धियों के प्रति उचित व्यवहार, दास तथा भृत्यों के प्रति उचित व्यवहार, मित्र, स्वामी, परिचित, सहायक तथा परिवार के प्रति उचित व्यवहार, प्राणियों की हिंसा न करना तथा उन पर दया करना, दरिद्र एवं पीडित व्यक्तियों के साथ उचित व्यवहार और नम्रता, यथाशक्य क्षमा-भाव रखना आदि महत्त्वपूर्ण तथ्यों द्वारा पारिवारिक एवं सामाजिक गुणों के प्रति अपने उत्तरदायित्व को भलिभांति निभा सकता है। इन सभी पर आदर्श घर-परिवार, समाज तथा राष्ट्र का अस्तित्व निर्भर करता है। प्राकृत साहित्य में वर्णित कल्याणपरक तथ्यों को अपनाकर व्यक्ति, समाज, राष्ट्र और विश्व के कल्याण की कामना की जा सकती है।

understand. If only they would realize above all that an artist works of necessity, that he himself is only a trifling bit of the world, and that no more importance should be attached to him than to plenty of other things which please us in the world, though we can't explain them. Picasso clearly explained that art can't be mentioned in the verbal words, but it can only be experienced because its influence in every individual is so personal that it can't be generalized.

Abstract Art:

Visual art is also called as a metaphorical art. Art is reality, but it is situated on the boundaries of dream and reality where we can see it from memory. It can be said in this manner like, the things or events which are left behind from our observation or experiences; we can discover that through art. Art is the manifestation of lost sight, thought, memory and the mystery of our difference. The concept of abstraction has been prevalent in our life since ancient times. These elements have been seen in some form or the other in ancient, classical, folk arts. The concept of abstract art is nothing new. Rather, in the society we live in and the traditions, beliefs and religious beliefs we have, these abstract feelings and beauty have permeated for centuries. From the very beginning, artists started realizing that the beauty of the artwork comes from its abstract nature. Whether that art is made of any style or period, its success depends only on its intangible aesthetic qualities, that is, an artwork is formed by the coordination of many basic elements like line, colour, space, texture, rhythm, tone etc. Not by its morphological representation. Plato said about abstract beauty that "circles, imports are such shapes which are not beautiful because of any external reason or

suitability, but aesthetic. Similarly, there is beauty in the pure use of colours. If seen, abstract art is a visual combination of our feelings and emotions, which the artist does not want to name, but his excitement begins to appear in the picture space by castings images or shapes, in which the shape is clear and vague than the ever recognized.

Figure 1 Ankuran, S H Raza, , Acrylic on canvas, 1992
Source: https://www.architecturaldigest.in/content/art-trust-reveals-retrospective-sh-razas-works-spanning-six-decades/

Many artists have associated this concept of abstraction with its own special contexts and meanings. Raza sees the "point" of his paintings in the context of his own life and experiences. If we understand the concept of abstraction in a limited sense, then it is possible that we will be unable to present its detailed concept. The existence of a figure in abstract art is inspired by its special contextual touch and extremely abstract emotions. Beauty, joy and rasa are closely related in artwork which cannot be separated from each other. Rabindranath Tagore describes beauty, joy and rasa

etc. as abstract expressions of the artwork, which can only be felt. The intense desire to express the inner beauty in abstract forms revealed its inner form and quality through abstraction by banishing the external substance and resemblance to the object. Inspired by this line of thought, Kadiski stunned the then audience by composing the first abstract painting in 1910. Kandisky has repeatedly stated in his views that only the language of abstract forms.

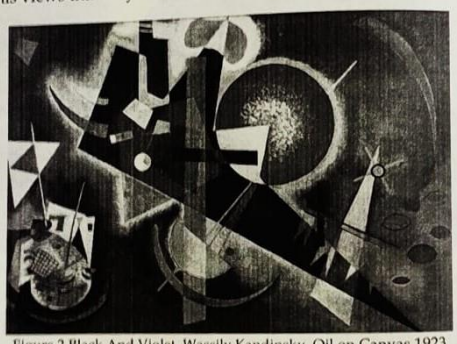

Figure 2 Black And Violet, Wassily Kandinsky, Oil on Canvas,1923
Source: https://www.wassilykandinsky.net/work-234.php

When abstract art was born in the 19th century, the argument was made to present it with a perspective of the illusion of visual reality. Its definition states that when an artist creates a combination in visual language consisting of shape, form, line, color, in which his freedom and perception acquire a visual context, then it, is called abstract art. The path of abstract art is different, it does not try to present the known truth. for the painter shape is just his sense with whi

he creates the abstract art, but the nectar painting would probably take this argument to its climax. If the form of the unknown is not fixed, then it is not possible to explore it with the help of known shapes.

Psychology of the Art:

It is the scientific study of various cognitive and emotional processes which is accelerated by seeing the aesthetic artefacts like watching painting or touching a sculpture. This focus on the experimental methods to measure qualitatively about the psychological responses to art and it includes the neuro-imaging techniques. Abstract art gives us no boundaries of right and wrong. It is open to the viewer's interpretation. It provides the observer the freedom to explore the art with his or her own cognition. It does not contain recognizable objects or themed so sometimes it makes the observer uncomfortable as sometimes he or she faces the difficulties in interpreting the artwork. Abstract paintings do not directly picture anything which is in real physical world.

Brain and Abstract Art:

Our brain is the most complex thing in the whole universe. It uses the top down and bottom-up processing for all analysis. Brain is always finding the familiarity and meaning to the patters as to make it a sense. Art is obviously free from the restrictions which are imposed by the visual system during our daily life. In an FMRI imaging study according to Kawabata and Zeki (2004) various activity evoked at localized and specific brain regions when they demonstrated the different categories of painting like landscape, portrait and still life. When abstract art was shown it did not activate a unique localized brain region. Instead, it activated the entire brain regions which are

related to other categories also. In fact, it can be assumed that there would be neural correlated for the specific cognitive category recognition of abstract art. Kawabata and Zeki (2004) and Vartanian and Goel (2004) found that it should not be expected a unique brain activity related to abstract art. Abstract art viewed does not belong to any other specific category. Lengger et al. (2007) founded that abstract stimuli evoked more positive emotions. This study was done in combination of behavioural and low resolution electromagnetic tomography analysis. He studied that representational artworks were found to be more interesting and were also better understood and also observers felt more association with it. In representation art there was higher activation in the left frontal lobe and bilaterally in the temporal, frontal and parietal lobe, limbic system. The increased brain activities for the representation art consist of the process of object recognition, memory and association system. Solso (2000) studied brain activity by comparing the brain activity of portrait artist and non- artist while drawing face. Brain activity of artist showed less activity in face processing areas (posterior parietal) than that of the non-artist. The lower level of activation of the artist face recognition area indicates that he may be more efficient in the processing of facial feature. While looking at a painting or a beautiful sculpture or any other artwork it increases the blood flow to the brain by 10 percent which is as much equal to the looking to someone whom we love. There is a process named embodied cognition which starts when we look at a piece of art. The more we watch, the more we analyse and we place ourselves to the scene and can actually feel the quality of art. In embodied cognition the mirror neurons in the brain turn things into the actions, movement and energy

which we seen in art into the actual emotions we can feel. The studies related to neuro-anatomical which used FMRI scans showed that representational paintings were more preferred over the abstract paintings. FMRI results revealed that activity in the right caudate nucleus decreased in response to decreasing preference for paintings, whereas the activity in left cingulated gyrus, bilateral occipital gyri, bilateral cerebellum increase in response to increasing preference for paintings. EEG brain scans revealed that there was less arousal was showed by the non- artist as compared to artist while watching the abstract arts whereas in figurative art both artist and non- artist had comparable arousal and the focused attention and evaluation of the art. From all these studies it may be concluded that abstract art seem to reduce the brain activity as compared with representational art which represent to the relevant control. These results indicate that the analysis of abstract art evokes less focal brain activation.

Abstract Art and Personality, Thinking Style:

Various studies have done in relation to the personality, thinking style and their art preferences. The person's choice of art can be useful to measure the type of personality. NEO Five factor inventory which is used to measure big five factors of personality after viewing abstract arts and representational arts. The personality which seeks to thrill and adventure, and Conscientiousness was positively correlated with the choice of representational art and disinhibition and neuroticism was related positively with abstract arts. Openness to experience was linked with both types of arts. Utmost abstract art is preferred by the individual who wants something new, they are open minded and are field independent thinkers. The abstract

thinking type individuals who have very low desire of orders are the viewer who loves to watch abstract art as they enjoy the task of exploring their capacities of organizing the disorganized content. It is clear that when a viewer sees a representational or realistic art it is the actual thing he is seeing like a human, nature, animal as the things we are familiar with. But when the abstract art is watched the brain faces difficulty in finding familiar objects. And then eyes move more on whole of the painting and not focusing on the specific objects. In a study held in 2011, it was observed that in response to the paintings of Jackson Pollock's fractal paintings the people used to move their eyes more uniformly across the whole canvas. The study published in Proceedings of the National academy of sciences points that how the viewing of abstract art is related to the psychologically closely or distantly they viewed it. In this study the researchers gathered eight hundred and forty subjects and was asked to view the artworks which was defined as purely abstract, having a clearly defined object, or partly abstract with a definable object. The subjects were asked to imagine that they were going to decide where to place the paintings on display. They could place the art according to their preferences either in gallery around the corner or in another state and also, they can show the date according to their timeline (in future, or tomorrow). The subject chose to place the abstract works in a distant gallery in the future than to do the same with the more grounded works. This shows the tendency of the association of abstract art with faraway places, and it indicates that we tend to place psychological distance between ourselves and abstract art. According to the psychological concepts abstract notions are seen as a very distant concept. Psychological distance is

the mental distance between self and other paces, events, and things.

Conclusions:

Abstract art free us from the boundaries of reality and watching the abstract art is to explore within oneself which is the reinforcement also. It enables us to flow in the inner states, create new emotional associations and activate the brain states that are harder to access. Abstract artist puts his/her inner self in his/her creative art whereas viewer of that art puts his/her emotions and feelings in the artist artwork. So it can be said the abstract art allows us to represent our inner conflicts, complexes, emotions, cognitions in the means of a beautiful artwork.

Effectiveness of Art therapy and Sandtray Therapy in the treatment of Autism Spectrum Disorders

Ishita Aggarwa
Yusra Asif
Anchita kumar
Shvangini Uberoi
Daulat Ram College, University of Delhi, Affiliated to Amity University, Noida

Abstract

Symbolism is one of the primary sources for exploring one's psyche. Expressive art therapies are based upon this idea. They utilize the therapeutic nature of expressing itself as the art becomes the medium for one's healing. With growing attention on benefits of various expressive arts modalities, empirical evidence demonstrates how efficient and effective they are for diagnosing and treatment of the clinical population, including neurodevelopmental disorders like Autism Spectrum Disorders, ADHD, and many more. Moreover, to develop a deeper understanding, specific implications of Art therapy and Sandtray therapy in autism spectrum disorders are emphasized.

Keywords: *Autism, Art, Play, Therapy, Psychology*

Introduction:

Autism Spectrum Disorders (ASD) are a group of phenotypically heterogeneous neurodevelopmental syndromes characterized by impairments in social communication and behavioral flexibility (Sadock, 2007), often accompanied by cognitive underpinnings directly impacting human behavior (Lord et al., 2020). The DSM-5 criteria for ASD includes persistent deficits in social

Title: Reshaping the business world post-COVID-19 : management strategies for sustainable behavior change / edited by Arvind K. Birdie, PhD, Ruchi Joshi, PhD.

Description: Palm Bay, FL : Apple Academic Press, 2024. | Series: 21st century business management | Includes bibliographical references and index. | Summary: "The COVID-19 pandemic dramatically changed our normal-both in life and in business. The timely volume provides a map of how the world has been significantly changed by the post-COVID-19 pandemic, not only in terms of work and business life but also linking other areas of personal life as well. The volume explores the diverse impacts of the pandemic on businesses and workplaces, addressing topics such as changes in organizational structures, operations, and marketing and consumer behavior. Sharing their rich insights and perspectives on today's business world, the authors also look at personal psychological well-being, the role of spirituality, employee satisfaction, an organization's future competitiveness, and quality of life have been affected and changed by the COVID-19 pandemic. Chapters discuss the challenges and complications of flexible and hybrid working styles and digital collaboration platforms such as Microsoft teams. Other topics include changed consumer choices and shopping psychology, internet addiction, mental health challenges, new psychological aspects of the art and culture industry, and more. The authors also share effective strategies for creating work-life balance and improving psychological well-being and for navigating the "new normal." Reshaping the Business World Post-COVID-19: Management Strategies for Sustainable Behavior Change will be valuable for both industry and academia as it covers concepts of business from various perspectives. The book is sure to help managers of all types navigate the new normal"-- Provided by publisher.

CHAPTER 2

Hybrid Working: The Future of Organizations

TARUN KUMAR SHARMA

Assistant Professor, Department of Psychology, Mohanlal Sukhadia University, Udaipur, Rajasthan, India

ABSTRACT

COVID-19 pandemic is considered a massive unplanned experiment in the world of work. The organizations were able to sustain its functioning by adopting work-from-home (WFH) policy. The experiences of remote working led us to understand that work can be performed with optimum productivity in WFH mode as well. The organizations like Microsoft and others have done extensive surveys to understand hybrid working perceptions among the employees. Hybrid working, its models and how different occupations/organizations differ in the possibility of adopting hybrid work arrangements is discussed.

Surveys such as Work Trend Index 2021 by Microsoft have revealed that the future of organizations is Hybrid work. The other surveys Riverbed/Aternity Hybrid Work Global Survey 2021, KPMG CEO 2021 outlook survey, NASSCOM have also reported the similar findings. The perspectives of Satya Nadella, Sunder Pichai, Mark Zuckerberg, Mark Dixon, and organizational perspectives by TCS, Goldman Sachs, and JP Morgan on Hybrid working are discussed.

However, hybrid work arrangements come with certain challenges and complications to be dealt with. The organizations would have to develop norms and policies to maintain optimum productivity and tracking the
